Limitation of liability: Neither Nortel Networks nor any of its agents or suppliers shall be liable for any indirect, consequential, incidental, or exemplary damages, or economic losses (including damages for loss of business profits, business interruption, loss of business information and the like), arising from the use, inability to use, or performance of the software or this license agreement, even if Nortel Networks or such agent or supplier has been advised of the possibility of such damages and/or losses, and whether any such damage and/or loss arises out of contract (including fundamental breach), tort (including negligence), or otherwise. The entire liability of Nortel Networks for any claim or loss, damage or expense from any cause whatsoever, whether arising out of contract (including fundamental breach), tort (including negligence), or otherwise shall in no event exceed the price paid by you under this license agreement. In some jurisdictions you may have additional rights, in which case some of the above may not apply to you.

Publication history: North American

October 2006

(I)SN09U is an extension of the (I)SN09 software release and supersedes both (I)SN09 and (I)SN09FF for CVoIP applications. (I)SN09 continues to be supported for TDM-only applications. The (I)SN09U software release incorporates all capabilities of (I)SN09, (I)SN09FF, and additional corrective content delivered as part of Nortel's (I)SN09 software robustness program. (I)SN09, (I)SN09FF, and (I)SN09U are valid terms for use within the (I)SN09U software release.

Version 01.4 Standard release for (I)SN09U, combining content from SN09 and SN09FF.

RelDoc Introduction

TDM and Carrier VoIP SOFTWARE

PRODUCT COMPUTING MODULE LOAD RELEASE DOCUMENT

(PCL) Release Document

This release document is supplied for each Software Stream for the North American load. This release document provides software feature information pertinent to the new software load.

A status of DRAFT or PRELIMINARY means the final feature content of the software release has not been finalized and features may be added or deleted without notice. A status of STANDARD indicates that the feature content of the software release is firm.

The release document consists of the following sections:

FEATURE CONTENT
This section provides information concerning TDM and Carrier VoIP system features associated with software releases. Each office configuration is customized to meet Telco/Carrier requirements. The following subsections include information necessary to determine that system software changes have occurred since the last software release.

> ***Note:*** Only features NEW or CHANGED in the release(s) covered by the document are included

CROSS REFERENCE TABLES
This section contains tables to make it more efficient to find information. A description of the tables precedes them.

The following sections provide information necessary to support changes applicable to the new software release. Only features that impact a section category are included; therefore, some sections may be left out of this NTP because none of the features for this release had an impact to that section.

- Functional Descriptions (FN) -summarizes the functions of the feature

- Fault Management (FM)
  - — Logs (LG) -indicates major additions/changes to the LOGs
- Configuration (CN)
  - — Data Schema (DS) -indicates major additions/changes to the Data Schema table
  - — Service Orders (SO) -indicates major additions/changes to the Service Orders
  - — User Interface (UI) - indicates major additions/changes to the User Interface
- Accounting (ACC)
  - — Automatic Message Accounting (AM) -indicates major additions/ changes to the AMA
- Performance (PF)
  - — Operational Measurements (OM) -indicates major additions/changes to the OM groups

How To Use the Feature Content Section

The feature content software section contains the documentation for the features new or changed in the release. There are tables included to help in the reading of the feature content section.

The items in the tables are feature numbers and feature functional groups. Features are designed by NT against an NT featid.

A functional group is made up of several features.

- Table1: Feature to Functional Group Cross Reference

  These tables list all features new to the release that may be included in the release document. The functional group is indicated along with the Nortel featid and its title against which the documentation has been written.

- Table 2: Functional Groups to Feature Impacts Cross Reference

  These tables list all documentation listed in the feature content section. As stated above, the documentation is sorted first by feature functional group, and then by featid within the functional group. This table indicates which sections (for example, FM, CN, PF, or ACC) are included in the release document.

(I)SN09U Feature Subset Cross Reference Tables: North American Features

Feature to Functional Group Cross Reference

Table 1 shows North American feature IDs, feature titles, and the corresponding functional group (under Stream and release).

Note: Features available in Nortel's FMDOC library show a version/issue number (i.e., AA05, etc.), while the features obtained from other sources do not have a version/issue number.

For details on specific features, refer to the FN sections.

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00007143.AB02	IPSec Integration with MS2010	Core23

A00009043	CS2K SS SIP Lines Provisioning Support	MCS09
A00009045	CallP Checkpointing Support	MCS09
A00009078.AA11	ICM Dual CTI	Core22

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00009085.AA06	ACD & ICM Capacity Expansion	Core22
A00009091.AA33	Equal Access (EA) LPIC Privilege Routing	Core22
A00009092	CS2K MSM SIP Lines Cisco 7960 Client	MCS09
A00009129.AA11	Controlled Hot Swact	Core22, NCGL09
A00009153.AA02	H.323 RLT Development	GC09
A00009156	USP-Compact Hardware	USP11
A00009158.AA05	M3UA over SCTP from Core to USP	Core22
A00009173.AA06	Linux <-> SOS Messaging	Core22
A00009182.AA02	Nortel Carrier Grade Linux Persistent Memory Application Programming Interface	NCGL8
A00009189	SESM support for 64 character FQDN	CS2M09
A00009190.AA23	Universal Carrier Protocol (UCP) C7UPTMR Enhancements	UCS22, GC09
A00009200.AA14	Packet Trunking Trunk Test: Milli-watt Tone Swap	Core22, GC09
A00009204.AA09	Siren Call Agent Customer Visible Capacity Tools	Core22
A00009207.AA05	DPT Trunk Testing Support	Core22
A00009208.AA12	SN09 180K Lines Support	Core22
A00009218	MG9K Data Audit Robustness	MG9KEM09
A00009227	NPM Robustness	MG9K09, CS2M09, MG9KEM09, GC09
A00009230	CS2000 Session Server Linux Support	MCS09
A00009235.AA09	TLS for SIP	NCGL8, NGSS09
A00009239.AA09	Services for SIP Lines	Core22, GC09
A00009241.AA06	NCAS and QSIP Development on CS2K SS	MCS09

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00009252.A02	Multi-Time Zone AMA Enhancments	Core22
A00009280.v3	MG9K Line Circuit Enhancements	MG9KEM09
A00009282	Emergency Stand Alone (ESA) Multiple Level Precedence and Preemption (MLPP) for MG9KEM	MG9KEM09
A00009289	IEMS (Integrated Element Management System) - 10 Minute Default on User Inactivity Timer	IEMS09
A00009292	IEMS: UserID-based Partitioning by NE	IEMS09
A00009294.AA11	T.38 Annex D interworking with SIP	GC09
A00009310	SSPFS Restricted Access Shell	CS2M09, SPFS09
A00009311	SSPFS Dark Office backup	SPFS09
A00009313	SSPFS SN09 Upgrades and ESD Support	SPFS09
A00009315	Detect failures from syslog and generate alarms	SPFS09
A00009316	Backup and Restore Enhancements	SPFS09
A00009320, A00009336	Remote Ping and Traceroute for Gateway Controller and SSPFS Platforms	IEMS09, GC09
A00009332.AA14	P-Time and Codec Negotiation Selection Policy	CS2M09, GC09
A00009337.AA12	PacketCable 1.0, 1.1, and 1.5 Compliance	Base22, GC09
A00009339.AA16	Packet Cable T.38 Support	CS2M09, GC09
A00009353.AA10	GWC Unit Availability/ Health Monitoring	GC09
A00009359.AA06	HW Intro of MCPN905 for Compact Call Agent	NGCL8
A00009361	CICM: Enhancement to IP Phone 2001 CICM client	CICM9
A00009362	IP Phone 2007 User Interface support	CICM9
A00009364	CICM End-of-call QoS Reporting	CICM9
A00009365	Mid-call Session Description Protocol (SDP) renegotiation	CICM9

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00009375 &A00009376	CICM Third-party Corrective Content Patching & CICM Selective Binary Component Patching	CICM9
A00009378.AA07	LI Support of SIP Lines	Core22, GC09
A00009417	Cold Cache Recovery	MCS09
A00009418	MCS as a 3G Application Server	MCS09
A00009443.AA07	T.38 Annex D for NGSS	GC09, NGSS09
A00009446.AA01	M2UA/SCTP Protocol for PVG SS7 backhaul support	USP11
A00009463.AA08	CBM to Support Centralized User Authentication with IEMS	SDM22
A00009470.AA09	SDM to support Security Assertion Markup Language (SAML) NSSwitch client	SDM22
A00009508.AA12	Automatic Message Accounting Session Initiation Protocol (SIP) Line Identification	Core22, SDM22
A00009513.AA07	PMA for SIP Lines	GC09
A00009514.AA25	CS2K-MCS Interop for SN09	NGSS09
A00009515.AA14	Out-of-Band Interop with MCS	NGSS09
A00009520.AA05	Trunk blocking tools for MG4K and GWC on SN09	Core22
A00009530.AA07	H248 & xUA NAT traversal for CPE Gateways	CS2M09, GC09
A00009532	Support host to host tunnels for all northbound OSS connections	IEMS09
A00009550.AA08	CBM-NPM Patching Convergence	SPFS09, SDM22
A00009576.AC04	H.323 RASLess Provisioning	CS2M09.1, GC09.2
A00009610	IEMS Calix Integration	IEMS09
A00009611	IEMS Keymile Integration	IEMS09

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00009612	Restricted Shell Access	IEMS09
A00009614	Tamper-proof Key Storage and Event Generation	IEMS09, SPFS09
A00009616	IEMS Backward Compatibility and Upgrade	IEMS09
A00009651	Meet Me Web Collaboration Multilingual	MCS09
A00009655	BladeCenter-T RTP Media Portal	MCS09
A00009711	Multimedia Communication Server E911 Caller Hold	MCS09
A00009726	Addition of CALIX_C7 Gateway certificate	CS2M09
A00009777	IEMS Mediant 2000 Integration	IEMS09
A00009822	General Security Log When the User Logs Out	SPFS09
A00009823	Security Logging for SSPFS	SPFS09
A00009828	Granular Service Packaging	MCS09
A00009829	Subscriber Open Provisioning Interface Pro-ductization	MCS09
A00009830	Complete Re-IP Support	MCS09
A00009831	Patching	MCS09
A00009838.AA04	Removal of DCE from default install and install wizards	SDM22
A00009839.AA04	Ability to apply patches during ESUP upgrade	SDM22
A00009840.AA09	CBM IPSec Northbound Interface	SPFS09
A00009865	Add MCP820 supporting on SAM21 EM	CS2M09
A00009890	Provisioning for Media Proxy insertion for SIP lines	CS2M09
A00009893.AA12	Session Server Call Processing Overload	NGSS09
A00009905	Private and Public Name and Number Display	MCS09

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00009950 (CICM) &A00010293 (GWC)	Media Portal Removal for Inactive CICM Clients	CICM9, GC09
A00009951	Introduction of 221X Wireless handset	CICM9
A00010024.AA01	Nortel Carrier Grade Linux kernel emergency pool	NGCL8
A00010168.AA06	H.323 support for COnnected Line Presentation/ COnnected Line Restriction (COLP/COLR)	GC09
A00010251.AA01	Support for SCTP (Simple control transmission protocol) security on GWC (Gateway controller	GC09
A00010303.AA22	Map Level Service Control Application Programming Interface	Base22
A00010329	Remove ASPEN protocol support on PVG	PVG09
A00010452	LANComm Multi-home Enhancements	Base22
A00010490	Adding Support MCPN905-270 card in SAM21 EM	CS2M09
A00010567	CS2M - G729 CODEC for AAL2	CS2M09.1
A00010617	Addition of NUERA_BTX4K and MGCP_IAD_40 Gateway certificates lines (Corrective)	CS2M09
A00010742	GWC EM Enhancements to Support SIREN	CS22M09.1
A00010880.AA08	ABI SMU Support	Core23
A00011167	MG9KEM Central Userid and Password Support	MG9KEM09
A00011281	MS2000 IPSec Configuration via IEMS	IEMS09
A00011740	Packet Cable Multimedia for CS2K	MCS09
A00011746	Addition of LGRP_TYPE field to GW profiles (Corrective)	CS2M09
A00011827.AB14	GWC Autonomous SWACT	CS2M09.1, GC09.2

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00012001.V5	IEMS Call Server 2000 SIP Integration	IEMS09
A00012109.AA17	Session Server Shared Library Replacement (SLR) Patching	NGSS09.1
A00012183	Public Key Manager	MG9KEM09.1, IEMS09.1, SPFS09.1, CS2M09.1
A00012198.V2	GLC12 Coin Card Support from EM	MG9KEM09.1
A00012199	MG9K EM CPR Robustness	MG9KEM09.1
A00012210	Geo OA&M Automatic Backup and Accelerated Restore	SPFS09
A00012215	Global Line Card Field Programmable Gate Array	MG9KEM09.1
A00012223, A00012217, A00012225	SESM Support for SIP Lines, Part 2	CS2M09.1
A00012242	TME-CD with GSM Wireless Client, Ph-1	MCS09.1
A00012273.AA14	SIP Lines: Call Forwarding Indication	Core23, MCS09.1, GC09.1
A00012308.AA19	SIP Lines Services: PRK, DPRK, CPU	Core23, GC09.1
A00012310.AA04	Hunt, SCMP, and CWT variant support for SIP Lines	Core23, CS2M09.1
A00012315.AA07	Telemetry for SIP Lines	Core23, MCS09.1, GC09.1
A00012317.AA17	Session Initiation Protocol (SIP) Services - Automatic Call Back (ACB) and Automatic Recall (AR)	Core23, MCS09.1, GC09.1
A00012321.AB01	SIP Services: Long Distance Alerting (LDA)	Core23, MCS09.1, GC09.1
A00012322.AA07	Session Initiation Protocol (SIP) Services - Busy Line Verification (BLV)	Core23, GC09.1

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00012323.AA13	Session Initiation Protocol (SIP) Services - Directed Call Pickup with Barge-in (DCBI) and Directed Call Pickup Barge-in Exempt (DCBX)	Core23, MCS09.1, GC09.1
A00012325.AA05	SIP Lines: Teen Line	Core23
A00012326.AA03	SIP Lines: Authentication and Authorization	Core23
A00012385.AA24	SIP Lines MADN Support	Core23, MCS09.1, GC09.1
A00012386	Media Gateway 9000 Public Key Infrastructure	MG9K09.1
A00012390.AA11	Call Transfer Screening for SIP Lines	Core23
A00012402.AA15	911 Hold/Ringback Support on SIP Lines	Core23, MCS09.1, GC09.1
A00012403.AA08	Data Protection for SIP Lines	Core23
A00012410.AA06	Support SIP lines for Malicious Call Hold	Core23
A00012470.AA08	Compact Call Agent - Support for NA/Intl Hybrid Market	CA09, SDM23
A00012478.AA14	Compact Call Agent: Geo Support for GigE	NCGL9, CA09
A00012506	Border Control Point (BCP) Operational Measurement (OM) Enhancements	MCS09.1
A00012526.AA12	TDM Call Recording Feature	Core23
A00012527.AA22	Provisioning of CS2K trunks on GW and Carrier basis	Core23
A00012528.AA16	ICM Queue Expansion	Core23
A00012538, A00012537, A00012539	SIP Lines Support - Part 2	MCS09.1
A00012569.AA22	NI2 PRI/ ISUP UUI over SCAI	Core23, GC09.1
A00012570	Disabling Non-secure Network Services in SSPFS	SPFS09.1

Table 1 Feature to Functional Group Cross Reference

Featid	Title	Stream and release
Note: Core is comprised of Base/TL, CCM, CNA, CSP, MSH, SHR, and UCS streams.		
A00012571	CBM User Group Improvements	SDM23
A00012622	Platform HW Alarm Reporting	MCS09.1
A00012635	Netra 240 146 GB Disk Drive Upgrade	SPFS09.1
A00012735.AA13	Session Server Fault Handling Enhancements	NCGL9, CA09
A00012766 (Refer to A00012470)	SDM/CBM800 connected with BRISC to CBM850 connected with CCA cutover	SDM23
A00012843	IEMS support for MDM security Interface changes	IEMS09.1
A00012889	Passphrase Protected Keys for SSH	SDM23
A00012893	BCP 7200 VLAN Tagging	MCS09.1
A00012905	ERS8600 Alarm Mapping Correction in IEMS	IEMS09.1
A00012974	Correct Execdata mismatch between GWC EM and Core	CS2M09.1
A00013063	PacketCable Multimedia for MCS and Carrier	MCS09.1
A00013457.AA01	Message Waiting Indication using SIP VM/UM based on RFC 3842	Core23
A00013508.V7	System Manager Auto-Failover Support	IEMS09.1
A00013935.AA04	PKMTA Extraction for DPT Calls	Core23, GC10
A00014049.AA02	GWC and SESM support for AAL2-G726-32 codec in IP Network	GC09.2, CS2M09.1
CR Q01333369	Triggering gateway capabillities audit while changing T.38 network option on CS2K with TGCP gateways	Core23

Functional Group to Feature Impacts Cross Reference

Table 2 is organized alphabetically by functional group. Within each group, the features are listed numerically. If a Feature belongs to more than one group, it

appears in each group to which it belongs. The table also indicates which sections are included for a given feature (for example, FN, FM, CN, PF, or ACC) in the release document.

Table 2 Functional Group to Feature Impacts Cross Reference

Functional Descriptions List (FNs)

Introduction

This chapter describes new and changed North American features that are planned for this release.

Note: Features available in Nortel's FMDOC library show a version/issue number (i.e., AA05, etc.), while the features obtained from other sources do not have a version/issue number.

Featid	Title
A00007143.AB02	IPSec Integration with MS2010
A00007217	ITRANS Media Proxy Selection
A00007269.AB19	NGSS Backup and Restore
A00007544.AB06	NCAS Link and SIP NMS Support based on RFC 3842
A00007547.AB13	SIP Lines Core Call Processing Support
A00007703.AA08	SDM/CBM Log Capacity & Robustness
A00007704.AB06	Table Access Manager Robustness
A00007814.V3	REX testing for MG9000 (Media Gateway 9000) from Element Manager
A00008090.AA14	SBA: Alternate Scheduled Closure of Billing Files
A00008323.AA05	H.323 64k UDI
A00008522	SESM Support for SIP Lines
A00008601.AA03	IW-SPM-IP Fully Provisionable Codec Lists for G.711/G.729

A00008629.AA08	GEM-II AAL2 IW-SPM SN09 Core Preparation Work
A00008724.AA04	OMDD Enhancements and Robustness
A00008740	SN09 Clock Sync Robustness
A00008858	CS2M and MG9KEM User Inactivity Time-out
A00008916.AA02	Gateway Controller Lines Density Increase
A00008969	ATM50 SSI Monitoring, Corrective
A00009011.AA02	TOPS Internet Protocol (IP) Security Enhancements
A00009012.AA10	TOPS OSSAIN Service Enhancements
A00009013.AA09	TOPS announcements via UAS/AMS
A00009026.AA08	RMGC Security
A00009027.AA04	Global Network Product Support Trace Tool Enhancements
A00009028.AA12	CS2K MSM SIP Lines OAM Support
A00009036.AA07	Table HOMELRN Option SITE Expansion
A00009043	CS2K SS SIP Lines Provisioning Support
A00009045	CallP Checkpointing Support
A00009078.AA11	ICM Dual CTI
A00009085.AA06	ACD & ICM Capacity Expansion
A00009091.AA33	Equal Access (EA) LPIC Privilege Routing
A00009092	CS2K MSM SIP Lines Cisco 7960 Client
A00009129.AA11	Controlled Hot Swact
A00009153.AA02	H.323 RLT Development
A00009156	USP-Compact Hardware
A00009158.AA05	M3UA over SCTP from Core to USP
A00009173.AA06	Linux <-> SOS Messaging

A00009182.AA02	Nortel Carrier Grade Linux Persistent Memory Application Programming Interface
A00009189	SESM support for 64 character FQDN
A00009190.AA23	Universal Carrier Protocol (UCP) C7UPTMR Enhancements
A00009200.AA14	Packet Trunking Trunk Test: Milli-watt Tone Swap
A00009204.AA09	Siren Call Agent Customer Visible Capacity Tools
A00009207.AA05	DPT Trunk Testing Support
A00009208.AA12	SN09 180K Lines Support
A00009218	MG9K Data Audit Robustness
A00009227	NPM Robustness
A00009230	CS2000 Session Server Linux Support
A00009235.AA09	TLS for SIP
A00009239.AA09	Services for SIP Lines
A00009241.AA06	NCAS and QSIP Development on CS2K SS
A00009252.A02	Multi-Time Zone AMA Enhancments
A00009280.V3	MG9K Line Circuit Enhancements
A00009282	Emergency Stand Alone (ESA) Multiple Level Precedence and Preemption (MLPP) for MG9KEM
A00009289	IEMS (Integrated Element Management System) - 10 Minute Default on User Inactivity Timer
A00009292	IEMS: UserID-based Partitioning by NE
A00009294.AA11	T.38 Annex D interworking with SIP
A00009310	SSPFS Restricted Access Shell
A00009311	SSPFS Dark Office backup
A00009313	SSPFS SN09 Upgrades and ESD Support
A00009315	Alarm Logging Failure

A00009316	Backup and Restore Enhancements
A00009320, A00009336	Remote Ping and Traceroute for Gateway Controller and SSPFS Platforms
A00009332.AA14	P-Time and Codec Negotiation Selection Policy
A00009337.AA12	PacketCable 1.0, 1.1, and 1.5 Compliance
A00009339.AA16	Packet Cable T.38 Support
A00009353.AA10	GWC Unit Availability/ Health Monitoring
A00009359.AA06	HW Intro of MCPN905 for Compact Call Agent
A00009361	CICM: Enhancement to IP Phone 2001 CICM client
A00009362	IP Phone 2007 User Interface support
A00009364	CICM End-of-call QoS Reporting
A00009365	Mid-call Session Description Protocol (SDP) renegotiation
A00009375 & 9376	CICM Third-party Corrective Content Patching & CICM Selective Binary Component Patching
A00009378.AA07	LI Support of SIP Lines
A00009417	Cold Cache Recovery
A00009418	MCS as a 3G Application Server
A00009443.AA07	T.38 Annex D for NGSS
A00009446.AA01	M2UA/SCTP Protocol for PVG SS7 backhaul support
A00009463.AA08	CBM to Support Centralized User Authentication with IEMS
A00009470.AA09	SDM to support Security Assertion Markup Language (SAML) NSSwitch client
A00009508.AA12	Automatic Message Accounting Session Initiation Protocol (SIP) Line Identification
A00009513.AA07	PMA for SIP Lines
A00009514.AA25	CS2K-MCS Interop for SN09

A00009515.AA14	Out-of-Band Interop with MCS
A00009520.AA05	Trunk blocking tools for MG4K and GWC on SN09
A00009530.AA07	H248 & xUA NAT traversal for CPE Gateways
A00009532	Support host to host tunnels for all northbound OSS connections
A00009550.AA08	CBM-NPM Patching Convergence
A00009576.AC04	H.323 RASLess Provisioning
A00009610	IEMS Calix Integration
A00009611	IEMS Keymile Integration
A00009612	Restricted Shell Access
A00009614	Tamper-proof Key Storage and Event Generation
A00009616	IEMS Backward Compatibility and Upgrade
A00009651	Meet Me Web Collaboration Multilingual
A00009655	BladeCenter-T RTP Media Portal
A00009711	Multimedia Communication Server E911 Caller Hold
A00009726	Addition of CALIX_C7 Gateway certificate
A00009777	IEMS Mediant 2000 Integration
A00009822	General Security Log When the User Logs Out
A00009823	Security Logging for SSPFS
A00009828	Granular Service Packaging
A00009829	Subscriber Open Provisioning Interface Productization
A00009830	Complete Re-IP Support
A00009831	Patching
A00009838.AA04	Removal of DCE from default install and install wizards
A00009839.AA04	Ability to apply patches during ESUP upgrade

A00009840.AA09	CBM IPSec Northbound Interface
A00009865	Add MCP820 supporting on SAM21 EM
A00009890	Provisioning for Media Proxy insertion for SIP lines
A00009893.AA12	Session Server Call Processing Overload
A00009905	Private and Public Name and Number Display
A00009950 (CICM) &A00010293 (GWC)	Media Portal Removal for Inactive CICM Clients
A00009951	Introduction of 221X Wireless handset
A00010024.AA01	Nortel Carrier Grade Linux kernel emergency pool
A00010168.AA06	H.323 support for COnnected Line Presentation/COnnected Line Restriction (COLP/COLR)
A00010251.AA01	Support for SCTP (Simple control transmission protocol) security on GWC (Gateway controller
A00010303.AA22	Map Level Service Control Application Programming Interface
A00010329	Remove ASPEN protocol support on PVG
A00010452	LANComm Multi-home Enhancements
A00010490	Adding Support MCPN905-270 card in SAM21 EM (Corrective)
A00010567	CS2M - G729 CODEC for AAL2
A00010617	Addition of NUERA_BTX4K and MGCP_IAD_40 Gateway certificates lines (Corrective)
A00010742	GWC EM Enhancements to Support SIREN
A00010880.AA07	ABI SMU Support
A00011167	MG9KEM Central Userid and Password Support
A00011281	MS2000 IPSec Configuration via IEMS
A00011740	Packet Cable Multimedia for CS2K

A00011746	Addition of LGRP_TYPE field to GW profiles (Corrective)
A00011827.AB14	GWC Autonomous SWACT
A00012001.V5	IEMS Call Server 2000 SIP Integration
A00012109.AA17	Session Server Shared Library Replacement (SLR) Patching
A00012183	Public Key Manager
A00012198.V2	GLC12 Coin Card Support from EM
A00012199	MG9K EM CPR Robustness
A000012210	Geo OA&M Automatic Backup and Accelerated Restore
A00012215	Global Line Card Field Programmable Gate Array
A00012223, A00012217, A00012225	SESM Support for SIP Lines, Part 2
A00012242	TME-CD with GSM Wireless Client, Ph-1
A00012273.AA14	SIP Lines: Call Forwarding Indication
A00012308.AA19	SIP Lines Services: PRK, DPRK, CPU
A00012310.AA04	Hunt, SCMP, and CWT variant support for SIP Lines
A00012315.AA07	Telemetry for SIP Lines
A00012317.AA17	Session Initiation Protocol (SIP) Services - Automatic Call Back (ACB) and Automatic Recall (AR)
A00012321.AB01	SIP Services: Long Distance Alerting (LDA)
A00012322.AA07	Session Initiation Protocol (SIP) Services - Busy Line Verification (BLV)
A00012323.AA13	Session Initiation Protocol (SIP) Services - Directed Call Pickup with Barge-in (DCBI) and Directed Call Pickup Barge-in Exempt (DCBX)
A00012325.AA05	SIP Lines: Teen Line
A00012326.AA03	SIP Lines: Authentication and Authorization

A00012385.AA24	SIP Lines MADN Support
A00012386	Media Gateway 9000 Public Key Infrastructure
A00012390.AA11	Call Transfer Screening for SIP Lines
A00012402.AA15	911 Hold/Ringback Support on SIP Lines
A00012403.AA08	Data Protection for SIP Lines
A00012410.AA06	Support SIP lines for Malicious Call Hold
A00012470.AA08	Compact Call Agent - Support for NA/Intl Hybrid Market
A00012478.AA14	Compact Call Agent: Geo Support for GigE
A00012506	Border Control Point (BCP) Operational Measurement (OM) Enhancements
A00012526.AA12	TDM Call Recording Feature
A00012527.AA22	Provisioning of CS2K trunks on GW and Carrier basis
A00012528.AA16	ICM Queue Expansion
A00012538, A00012537, A00012539	SIP Lines Support - Part 2
A00012569.AA22	NI2 PRI/ ISUP UUI over SCAI
A00012570	Disabling Non-secure Network Services in SSPFS
A00012571	CBM User Group Improvements
A00012622	Platform HW Alarm Reporting
A000126235	Netra 240 146 GB Disk Drive Upgrade
A00012735.AA13	Session Server Fault Handling Enhancements
A00012766 (Refer to A00012470)	SDM/CBM800 connected with BRISC to CBM850 connected with CCA cutover
A00012843	IEMS support for MDM security Interface changes
A00012889	Passphrase Protected Keys for SSH

A00012893	BCP 7200 VLAN Tagging
A00012905	ERS8600 Alarm Mapping Correction in IEMS
A00012974	Correct Execdata mismatch between GWC EM and Core
A00013063	PacketCable Multimedia for MCS and Carrier
A00013457.AA01	Message Waiting Indication using SIP VM/UM based on RFC 3842
A00013508.V7	System Manager Auto-Failover Support
A00013935.AA04	PKMTA Extraction for DPT Calls
A00014049.AA02	GWC and SESM support for AAL2-G726-32 codec in IP Network
CR Q01333369	Triggering gateway capabillities audit while changing T.38 network option on CS2K with TGCP gateways

1: Functional Description (FN) A00007143

1.1 Feature name and Feature ID

A00007143: IPSec Integration with MS2010

1.2 Description

Media Server 2010, MS2010 is an audio server in the succession network and is responsible for announcements, lawful intercept, and conference ports. The MS2010 communicates its signalling messages via the audio Gateway Controller (GWC) which has one of the following profiles: AUDCNTL, AUDCNTLINTL, AUDCNTL_RMGC, AUDCNTL_RMGCINTL. The integrated element management system (IEMS) is the element manager for the MS2010 and is the supported interface for IPSec configuration on the MS2010.

This ICAF integrates the IPSec interactions between the audio GWC and the MS2010 as configured by the IEMS. There has been no additional development required on the GWC to support this feature as it relies on existing IPSec functionality and CS2M IPSec configuration tools. This integration tests that the new IPSec functionality on the MS2010 and the corresponding configuration interface on the IEMS work in conjunction with the existing functionality on the GWC and CS2M.

The documentation for using the IEMS graphical user interface for configuration and maintenance of the IPSec functionality on the MS2010 is in feature A00011281.

The documentation for general configuration and maintenance of the GWC IPSec functionality via the CS2M, is covered in the FCAP documentation NN10213-611 with the following considerations specifically for using this functionality for securing communication to the MS2010:

Key Exchange Method: The key exchange method used between the MS2010 and the audio GWC is IKE (internet key exchange).

IKE Cipher Algorithms: The MS2010 does not support AES encryption algorithm so the AES-CBC option should not be used on the GWC for IKE cipher algorithm.

IKE Diffie-Hellman key group: In order to properly match this value with the value configured on the MS2010 the user needs to know that Diffie-Hellman key group 1 on the GWC corresponds to dH-786-BIT setting on the MS2010 and Diffie-Hellman key group 2 on the GWC corresponds to dH-1024-BIT setting on the MS2010.

IPSec ESP Cipher Algorithms: The MS2010 does not support AES encryption algorithm so the option ESP-AES must not be used on the GWC for IPSec ESP cipher algorithm.

PFS: Diffie-Hellman key group: Perfect Forward Secrecy (PFS) is not supported on the MS2010 so this value must be set to NONE on the GWC

Fault Management: IPSec Fault management is covered in FCAP document NN10202-911 Gateway Controller Fault Management (no Kerberos logs would be applicable to this interface, only IKE management logs).

1.3 Hardware Requirements or Dependencies

None

1.4 Software Requirements or Dependencies

Depends on MS2010 support for IPSec and IEMS GUI for configuration and maintenance of IPSec for MS2010

1.5 Limitations and restrictions

None

1.6 Interactions

As with any other links that support IPSec, there is a performance degradation associated with applying security to the messaging link. The degradation for messaging to the MS2010 would be comparable to the degradation experienced on any of the other links that currently support IPSec.

1.7 Glossary

Term	Description
MS2010	Media Server 2010
IEMS	Integrated Element Management Server
IPSec	Internet Protocol Security
IKE	Internet Key Exchange
Diffie-Hellman	A key exchange method used in IKE phase 1 and perfect forward secrecy
PFS	Perfect forward secrecy

Term	Description
New term	**Definition**
no new terms	

2: Functional Description (FN) A00007217

2.1 Feature name and Feature ID

A00007217: ITRANS Media Proxy Selection

This feature is mapped to Actid A00007217 and A00009367. This FN covers the functionality added by both activities.

2.2 Description

Media Proxies (MPs) have been used in Internet Transparency features since SN06.2. They allow Media Streams to be sent to/from devices that are behind Network Address Translators (NAT).

Prior to this enhancement, the MPs were provisioned against Gateway Controllers (GWC). The MPs on the GWC were selected using a "round robin" approach when a call involving one of its subtending gateways required a MP. This did not completely satisfy customer requirements because a GWC could have Media Gateways (MG) from diverse locations. The round robin approach to MP selection could cause an MG to use a MP located a great distance from it. Another MP on the same GWC could have been a better choice because it was better located relative to the MG.

This SN09 activity will improve the method of selection of a MP by allowing customers to provision Media Proxy (MP) preferred groups. A MP preferred group will represent a subset of Media Proxies that are preferable for use in a particular part of the network configuration. For example a cluster of media Proxies in a particuar location could be put in a group to be used exclusively by a set of gateways in the same location. By enabling sub-division and restricted access of Media Proxies greater flexibility is given in the use of the MPs known to the GWC.

Media Proxy Groups can be allocated to Itrans Network Zones (Nats, LBLs and composite Nat/Lbl zones). The GWC will select the MP to use for the media stream at call setup time by finding the first Media Proxy Group in the Network Zone hierarchy linked to the Gateway and selecting an MP from that group on a round robin basis. Customers will be able to allocate MPs more efficiently (in terms of increased speed and cost savings) by grouping them according to location and reducing the distance travelled through the nextwork.

In addition to the capability to create preferred Media Proxy Groups, this feature will also retain the pre-SN09 capability to allow media proxies to be associated to GWCs. The media proxies associated to a GWC will be refered to as the GWC's default media proxies (see more detail below).

A Media Proxy may belong to more than one Media Proxy Group as well as a GWCs default media proxies. A Media Proxy Group may be associated with more than one Network Zone.

This feature also provides the capability to group Nat Itrans Network Zones into virtual private networks (VPNs). A VPN can contain one or more Nats. The VPN identifiers of the parties involved in a call will be used during call setup time to determine if a media proxy is required (see the call processing section below for more details).

Media Proxy Group (MPG) and Virtual Private Network (VPN) functionality will be included in the SN09 release and will be enabled in the CS2000 Management Tools User Interface. No additional action is required to enable this functionality.

This feature comprises provisioning enhancements and call processing enhancements.

2.2.1 Provisioning Enhancements

This enhancement will facilitate the creation, deletion and alteration of Media Proxy Groups (MPG) by means of a graphical user interface (GUI) incorporated into the CS2000 management Tools GUI. A MPG can consist of up to 5 MPs selected from a list of available MPs.

The pre-SN09 capability to provision media proxies against the whole GWC will remain. Media proxies that are provisioned against the GWC are referred to as the GWC's default media proxies, and can be used if no preferred Media Proxy Groups are provisioned. Thus, at provisioning time, a media proxy can be either:

1. Associated with one or more GWCs, but not be part of any preferred media proxy group. This is the retention of the SN08 functionality. This media proxy will be refered to as a default media proxy in SN09. And/or,

2. Made part of one or more preferred media proxy groups, And/or,

3. Made part of one or more preferred media proxy groups, and also be associated with one or more GWCs. I.e. a media proxy can be in one or more Media Proxy Groups, and also be a default media proxy for one or more GWCs.

A GWC may have none or several default media proxies associated to it.

The architecture is shown in Figure 1 below.

Figure 1 Functional Behaviour Diagram: Media Proxy Selection

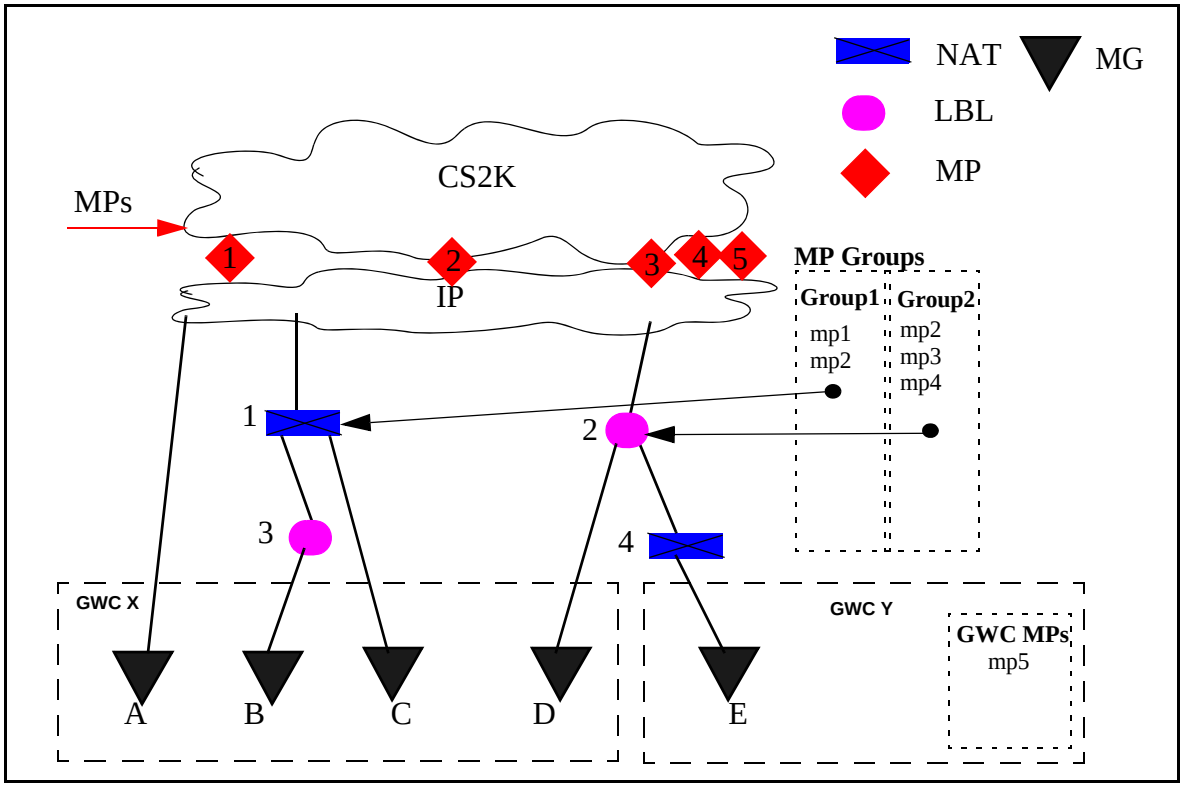

Figure 1 shows that MPs are assigned in MP Groups with some MPs being assigned as default MPs on a GWC. The MP Groups are then assigned to Nat, LBL and composite Nat/LBL Network Zones by the customer. If a call being set up on a MG requires a MP, the GWC would search the Itrans Middlebox hierarchy of the MG until it got to a NAT or LBL with a MP group. The MP would then be selected from the group on a round robin basis. If no MP Group was found in the hierarchy the GWC would select an MP from the default MPs provisioned on the GWC.

The following provisioning functionality will be added in this feature:

The capability to Provision a Media Proxy Group - a Media Proxy Group may be created with up to 5 Media proxies. A media proxy may be in more than one group and/or be one of the GWC's default media proxies.

The capability to modify a Media Proxy Group - The Media Proxies associated with a Media Proxy Group may be changed, and the number of media proxies in the group may be increased or decreased (subject to a maximum of 5 and minimum of 1). A Media Proxy Group that has been provisioned on a GWC(s) may not be modified unless it is first disassociated from the GWC(s). Disassociating the Media Proxy Group (s) from a GWC will affect call processing in that the Media proxies in the

group will not be available for selection for the duration of the modification operation.

The capability to query a Media Proxy Group - The Media Proxy Group may be queried as follows:

To return the media proxies in the group.

To return a list of all media Proxy Groups.

To return a list of GWCs that are provisioned with the Group.

To return a list of groups that have a particular Media Proxy.

The capability to delete a Media Proxy Group - The Media Proxy Group may be removed from the system. The Media Proxy Group must first be disassociated from any Itrans Network Zones that are present on any GWC.

The capability to associate a Media Proxy Group with an ITRANS Network Zone - A user may add a media proxy group to an Itrans Network Zone. A group may be associated with more than one Itrans Network Zone.

The capability to change the Media Proxy Group associated with an Itrans Network Zone - A user may change the Media Proxy Group that is selected for an Itrans Network Zone. This operation is likely to affect call processing and the availability of Media Proxies for the duration of the change.

The capability to associate a NAT Itrans Network Zone with a Virtual private network (VPN) - A NAT Network Zone may be assigned a VPN identifier. NAT Network Zones with the same VPN identifier are considered as being in the same VPN. Gateways may be moved to different network zones in a VPN even if the top-level network zones are different.

The capability to delete a VPN - A VPN may only be deleted if no NAT Network Zones are associated with it. This means that all Network Zones in a VPN must first be changed to remove the association with the VPN.

The capability to query a VPN - The NAT network Zones in the VPN may be queried.

The capability to Change a VPN - NAT Network Zones may be added or removed from a VPN by changing the VPN that a NAT Network Zone is associated with.

If any of the above listed actions fails to be executed on the server, the data will either be rolled back and the system restored to its original state or an alarm will be set to indicate a potential database mismatch. A message window will be displayed to alert the user to the provisioning fault.

2.2.2 Call Processing Enhancements

2.2.2.1 Media Proxy Selection During Call Processing.

During call setup, the GWC will determine whether or not the call requires a media proxy in order to facilitate call completion (see 2.2.2.2). If a media proxy is determined to be required, a media proxy is selected using the process in 2.2.2.3. If the selected media proxy is successfully contacted, it will be inserted into the media stream and call setup completed.

2.2.2.2 Criteria For Determining If A Media Proxy Is Required

Prior to SN09, whether or not a call required a media proxy to facilitate call completion depended on whether the parties involved in the call were behind NATs, and if so, whether the NATs of each party belonged to different Network Zones.

In SN09, whether or not a call requires a media proxy to facilitate call completion depends on whether the parties involved in that call are in the same virtual private network (VPN). A media proxy will be deemed to be required for call completion if either:

1. The two parties involved in the call belong to different VPNs. Or,

2. The call is an inter-domain SIP-T call, and the non-SIP-T media endpoint is not located in the common public domain. Or,

3. One of the endpoints is a SIP line.

2.2.2.3 Media Proxy Selection Process

At call setup time, if the GWC has determined that the call requires a media proxy to achieve call completion, a media proxy will be selected using the following process. At any point in the selection process, if a media proxy is successfully selected and contacted, then this media proxy selection process will stop and call processing will continue to insert the media proxy into the media stream, and set up the call.

MEDIA PROXY SELECTION PROCESS:

If it is determined that Early Slave Insertion of a media proxy is required, then the Slave GWC will "walk up" its Itrans Network Zone hierarchy, starting from the Itrans Network Zone adjacent to the Slave gateway, looking for a preferred media proxy group. It will select a media proxy, using a round-robin approach, from the first preferred media proxy group that it finds associated with a NAT, LBL or combined NAT-LBL zone. If none of the media proxies in that preferred media proxy group can be used, (e.g. all are out of capacity, or not active), then the Slave GWC will select a media proxy, using a round-robin approach, from its default media proxies.

If The Slave GWC does not have any default media proxies associated to it, or, if none of its default media proxies can be used (e.g. all are full to capacity),

then it means that the call required a media proxy, but no useable media proxy could be found. The call will then be taken down.

However, if Early Slave Insertion is not required, then the Master GWC will "walk up" its Itrans Network Zone hierarchy, starting from the Itrans Network Zone adjacent to the gateway, looking for a preferred media proxy group. It will select a media proxy, using a round-robin approach, from the first preferred media proxy group that it finds associated with a NAT, LBL or composite NAT-LBL zone. If none of the media proxies in that preferred media proxy group can be used, (e.g. all are out of capacity, or not active), then the Master GWC will select a media proxy, using a round-robin approach, from its default media proxies.

If the Master GWC does not have any default media proxies associated to it, or,if none of its default media proxies can be used (e.g. all are full to capacity), then the Master GWC will request the Slave GWC to perform media proxy insertion, provided that the Slave GWC has media proxies provisioned.

If Slave media proxy insertion is invoked by the Master GWC, the Slave GWC will perform a media proxy selection process that is the same as that described for Early Slave Insertion above.

2.2.2.4 Load Sharing Among Media Proxies

Load sharing among media proxies is implemented as follows:

1. Within each preferred media proxy group, media proxies are selected using a round-robin approach.

2. Selection of a default media proxy, from the default media proxies allocated to a GWC, is also performed using a round-robin approach

2.3 Hardware Requirements or Dependencies

There are no additional Hardware requirements for this feature.

2.4 Software Requirements or Dependencies

- The GWC should be running a software load of an equivalent stream to that of the SESM/GWC-EM, and should be running under a profile that enables ITrans functionality.
- The GWC should be running a software load that allows the use of a preferred Media proxy group.

2.5 Limitations and restrictions

A maximum of 5 Media Proxies may be assigned to a Media Proxy group.

A maximum of 20 Media Proxies are permitted on a GWC.

A maximum of 8 Media Proxy Groups are permitted on a GWC.

A maximum of 512 Media Proxy Groups can be provisioned in the system.

A maximum of 20 GWCs can be provisioned with a particular Media Proxy.

Only an Itrans Network Zone (Nat, LBL or composite Nat/LBL) may be assigned a Media Proxy group.

An Itrans Network Zone may be assigned only one Media Proxy Group.

A Media Gateway that does not have a media Proxy Group assigned via its Itrans Network Zone Hierarchy will use the default Media Proxies provisioned on the GWC.

Media Proxies must be provisioned before Media Proxy Groups can be created.

Media Proxy Groups must be provisioned before association with an Itrans Network Zone.

Only a Nat or Composite Nat Network Zone can be provisioned with a VPN.

A VPN cannot be deleted if it contains Nat Zones that are associated on a GWC.

A Media Proxy Group cannot be deleted if it is associated with a Network Zone that is on a GWC.

A Media Proxy cannot be deleted from the system if it belongs to a media proxy group.

A Media Proxy cannot be deleted from the system if it is a default media proxy on a GWC.

A Media Proxy Group cannot be changed if it is on a GWC. Changes to a Media Proxy Group and the Media Proxies in the group must be done in such a way that the Media Proxy Group is first removed from all GWCs. This can be done by disassociating the network zone with the group from GWCs or by changing the group associated with that network zone. Changes of this nature will affect the availability of Media Proxies (for call processing) for the duration of the change.

2.6 Interactions

Changes have been made to include the Media Proxy Group association with a Network Zone. These changes are, in part, on interfaces which are common to both the Call server 2000 Management Tools (CS2MT) and the Session Policy Controller (SPC). In particular the xml schemas used by the OSSGATE

interface for network Zones, are common to both systems. Therefore the changes made in the xml for the purposes of this feature are expected to be implemented in the SPC. The SPC implementation of the xml interface changes is not a part of this feature.

NAT traversal for CICM gateways is unchanged by this feature.

SIP line Provisioning is not affected by this feature. Any topology changes will flow through to the SIP GW to ensure that NAT traversal is correctly calculated. CS2K MP insertion will then proceed as normal. Media Proxy insertion by the SIP GW is unchanged and is done according to the existing SIP GW rules, using the common topology.

The provisioning of Media Proxy Group data brings changes to the following GUIs:

- GWC-EM Network Panel
- GWC Media Proxies Panel
- Add Itrans Network Zone Dialogs
- Change Itrans Network Zone Dialogs
- Itrans Network Zone Panels
- Network Devices Media Proxies Panel

See the GUI section in Configuration for full details of the changes to the GUIs.

See the OSS Gate section in Configuration for details of the xml changes.

See the Walkthrough section in Configuration for details of the provisioning use cases.

Term	Description
Media Proxy Group	a group of Media Proxies

3: Functional Description (FN) A00007269

3.1 Feature name and Feature ID

A00007269 NGSS Backup and Restore

3.2 Synopsis

This activity enhances the backup functionality provided by the NGSS Session Server for SN09. These enhancements include creating a new directory to store the backed up files, backup additional files not previously backed up, and provide a mechanism for the customer to change the backup time. It also documents a restore procedure for the various backed up components.

3.3 Background Information

3.3.1 NGSS Pre-SN09 Backup Capability

In SN07 and SN08 the NGSS Session Server performs a daily backup of the Solid database files into the following directory on each NGSS unit:

```
/opt/apps/database/solid/backup
```

The database backup is performed by an automatic timed command at 1 AM daily. The backup time can not be configured. A single copy of the database backup is stored on the NGSS.

3.3.2 NGSS SN09 Backup Capability

For SN09, this activity backs up the Solid database, certificates, commish, and web files on the NGSS Session Server.

All backed up files are placed in a TAR file on the following directory:

```
/data/bkresmgr/backup
```

The backup mechanism is controlled by a cron job running on the NGSS. The backup time can be configured by the customer. The backup cron job is set to run at 1 AM as a default setting.

Customers need to ensure that NGSS backup times are synchronized with the times set for IEMS backups.

It is strongly recommended that customers transfer the backups to an external server or location daily to protect against system or office outages.

NOTE: In SN09, both units will be backed up. As some files are different between them, customers are recommended to store the backups taken from both units.

3.4 Description

3.4.1 NGSS Back up Directory

Backup files are stored locally on the NGSS. A new directory is created to store the backed up files. A directory is created for this purpose is:

`/data/bkresmgr/backup`[1]

All backed up files are placed in a TAR file in the backup directory. The name of the backup file is in the following format:

`<hostname>.backupfile.date_time.tgz`

For example:

`vm0.backupfile.2005-03-14_09-47.tgz`

3.4.2 NGSS Backed up Files

The following files are backed up on the NGSS for SN09:

- Solid Database files
  - /opt/apps/database/solid/backup/solid.db
  - /opt/apps/database/solid/backup/solid.ini
  - /opt/apps/database/solid/backup/solmsg.out
- certificate files
  - /opt/base/share/ssl/gen_cert.txt
  - /opt/base/share/ssl/server.crt
  - /opt/base/share/ssl/trusted.crt
- commish files[2]
  - etc/hosts[3]
  - etc/ntp.conf
  - etc/sysconfig/network-scripts/ifcfg-eth0[4]
  - etc/sysconfig/netnodes

[1]This backup directory naming convention was introduced by the A00006979 Synchronized Backup and Restore activity for Succession products.

[2]Note: files in the etc/ directory are identical to those in the /persist directory. They can be backed up from either directory.

[3]This is unit specific data.

[4]This is unit specific data.

- etc/group
- etc/passwd
- etc/shadow
- /opt/base/synch_local/common/etc/ssh/ssh_host_dsa_key.pub
- /opt/base/synch_local/common/etc/ssh/ssh_host_key.pub
- /opt/base/synch_local/common/etc/ssh/ssh_rsa_key.pub

• web files

- /opt/apps/webint/jakarta-tomcat-4.1.30/conf/server.xml
- /opt/apps/webint/jakarta-tomcat-4.1.30/webapps/prov/jsp/redirect.jsp
- /opt/apps/webint/jakarta-tomcat-4.1.30/webapps/prov/jsp/redirect_SSPFS.jsp
- /opt/apps/webint/jakarta-tomcat-4.1.30/webapps/prov/jsp/redirect_no-SSPFS.jsp
- /usr/local/apache/htdocs/redirect_apps.php

All backed up files are placed in a tar file on the following directory:

```
/data/bkresmgr/backup
```

3.4.3 Restoring NGSS Backed up Files

In general the backed up files simply need to be returned to their original directories as documented above “NGSS Backed up Files” on page 53. The files should be applied to their respective directories after the commish and SIPGW installation steps have been completed and prior to unsuspending the SIPGW application.

Perform these initial steps to start the restore process.

1. Log into NGSS as root.
2. Transfer backup TGZ file to /data/bkresmgr/restore
3. If image is stored locally, copy it from /data/bkresmgr/backup

   ```
   cp /data/bkresmgr/data/backupfile.tgz /data/
   bkresmgr/restore
   ```

4. If image is stored externally, use NFS, SFTP, SCP, or read it from a CD/DVD/tape drive.
5. Go to restore dir

   ```
   cd /data/bkresmgr/restore
   ```

6. Un-compress the backup image into the current dir.

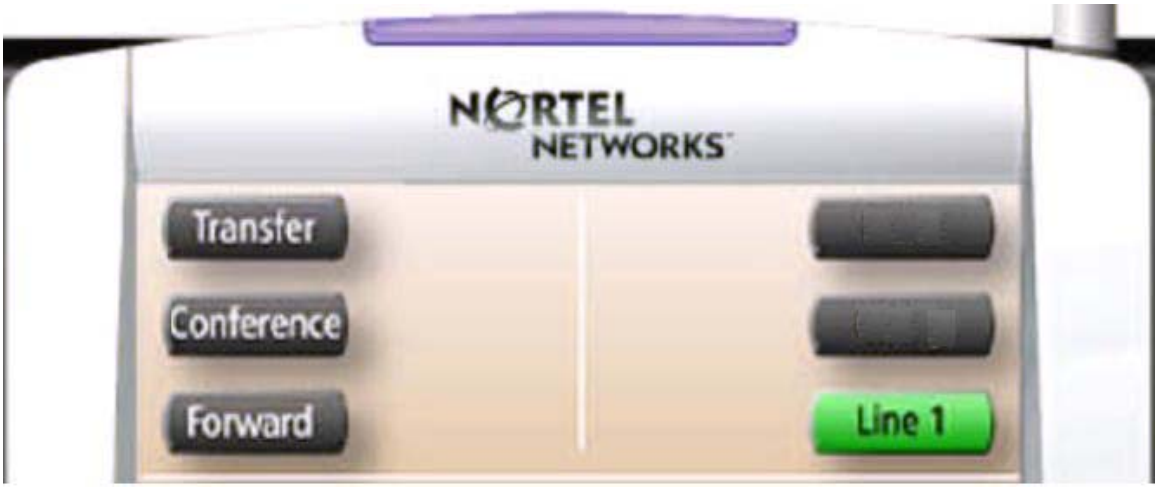
   ```
   tar -xzvf backupfile.tgz
   ```

The following sections provide a detailed procedure on how to restore files for each component that was backed up. Determine which components need to be restored. Follow the restore steps for that component if they are relevant to what needs to be restored. For instance, if the keys do not need to be restored, skip that step.

3.4.1.1 Restoring database from a backup copy

The following procedure is used to restore the database from the backup copy. The database is restored to its state when the backup was made. In general this procedure should only be followed when database corruption has occurred on both units of the NGSS. The database must be restored on the **active unit** of the NGSS.

1. Jam the Active Unit.
2. Suspend Call Processing
3. Copy over the database files[1]



```
chmod 700 /opt/apps/database/solid/backup/
solmsg.out
```

5. Run the restorebackup script as shown from the following directory:

```
cd /opt/apps/database/solid_install/

./restorebackup.sh
```

6. Unsuspend Call Processing
7. UnJam the Active Unit

Jamming the active unit is necessary to prevent the database from switching activity while its being restored. The database must be restored on the active unit. No action is needed to restore the database on the inactive unit. The database on the inactive unit is automatically updated by the active unit. Call processing should be suspended since the database will not be available.

[1]For each copy the system asks for confirmation. Please ensure the copy is correct before typing yes.

3.4.1.1 Restoring certificate

Stop the services which use the certificates and copy over the existing ones.

1. Restore **all** files

```
cp -i gen_cert.txt /opt/base/share/ssl/
cp -i server.crt /opt/base/share/ssl/
cp -i trusted.crt /opt/base/share/ssl/
cp -i server.xml /opt/apps/webint/jakarta-tomcat-4.1.30/conf/
```

2. Set the permissions on the files accordingly

```
chmod 644 /opt/base/share/ssl/server.crt
chmod 644 /opt/base/share/ssl/gen_cert.txt
chmod 644 /opt/base/share/ssl/trusted.crt
```

3. suspend the application
4. /opt/apps/webint/tomcatd stop
5. /usr/local/apache/bin/apachect1 stop
6. /usr/local/apache/bin/apachect1 start
7. /opt/apps/webint/tomcatd start
8. unsuspend the application

3.4.1.1 Restoring system data

Copy over and set permissions on the files that need to be restored.

1. Copy over the following files as needed

```
cp -i hosts /etc/
cp -i passwd /etc/
cp -i group /etc/
cp -i ntp.conf /etc/
cp -i shadow /etc/
cp -i ifcfg-eth0 /etc/sysconfig/network-scripts/
cp -i netnodes /etc/sysconfig
cp -i ssh_host_dsa_key.pub /opt/base/synch_local/common/etc/ssh/
cp -i ssh_host_key.pub /opt/base/synch_local/common/etc/ssh/
cp -i ssh_rsa_key.pub /opt/base/synch_local/common/etc/ssh/
```

2. Set the permissions on the restored files accordingly

```
chmod 755 /etc/hosts
chmod 755 /etc/passwd
chmod 755 /etc/shadow
chmod 755 /etc/group
chmod 755 /etc/sysconfig/netnodes
chmod 755 /etc/sysconfig/network-scripts/ifcfg-eth0
chmod 644 /opt/base/synch_local/common/etc/ssh/ssh_host_key.pub
chmod 644 /opt/base/synch_local/common/etc/ssh/ssh_host_dsa_key.pub
chmod 644 /opt/base/synch_local/common/etc/ssh/ssh_rsa_key.pub
```

3.4.1.1 Restoring web files

1. Copy over the following files

```
cp -i redirect*.jsp /opt/apps/webint/jakarta-tomcat-4.1.30/webapps/prov/jsp/
cp -i redirect_apps.php /usr/local/apache/htdocs/
```

Note: If additional web files need be restored then do a reinstall.

3.4.4 Configuring the backup time on the NGSS

The backup utility is run as a cron job. Cron is the name of a program that enables users to execute commands or scripts at specific times and dates. It is recommended that the backup utility be run daily on the NGSS during off peak hours. As a default setting the backup utility on the NGSS is scheduled to run at 1 AM daily.

Changing the scheduled time of the NGSS backup involves changing the cron programs configuration file: *crontab*. An entry in the crontab file is made up of a series of fields with each separated by a space. An example crontab entry follows:

0 1 * * * /opt/apps/database/solid_install/bkup_solprov.sh

A list of the fields follows:

minute hour day month weekday user cmd

minute: the minute of the hour the command will run on, range 0 to 59.

hour: thehour of the day the command will run on as specified on a 24 hour clock, range 0 to 23, where 0 is midnight.

day: the day of the month the command will run, e.g. to run a command on the 19th of each month, the day would be 19.

month: the month of the year the command will run on, range 0 to 12.

weekday: the day of the week the command will run, range 0 to 7.

cmd: the command/program to run.

To run a program daily set the minute and hour fields and place a ***** in the remaining fields (day, month, and weekday). In the previous example the bkup_solprov.sh program gets run at 1 AM daily.

Notes: Place a * in any unused fields. More than one value may be put into a field by separating the values with commas.

3.5 Hardware Requirements or Dependencies

N/A.

3.6 Software Requirements or Dependencies

N/A.

3.7 Limitations and restrictions

For security reasons *.key and *.keystore files are not backed up by this feature:

/opt/base/share/ssl/certificate.keystore
/opt/base/share/ssl/server.key
/opt/base/synch_local/common/etc/ssh/ssh_host_dsa_key
/opt/base/synch_local/common/etc/ssh/ssh_host_key
/opt/base/synch_local/common/etc/ssh/ssh_rsa_key

3.8 Interactions

N/A.

4: Functional Description (FN): A00007544

4.1 Feature name and Feature ID

A00007544: NCAS Link and SIP NMS Support based on RFC 3842.

4.2 Description

This development includes following two separate but interdependent design:

- Non-Call Associated Signaling (NCAS) link development.
- Session Initiation Protocol (SIP) based network message waiting service (NMS) support based on RFC 3842.

4.2.1 NCAS Link Development

The NCAS Link provides a light weight switching control point (SCP) like functionality. The NCAS link provides a non-call associated link between the Communication Server 2000 (CS2K) Session Server (SS) (formally known as Next Gen Session Server (NGSS)) and the CS2K Core (Brisk/88K, XA-Core and Compact/3PC). The NCAS link is used by the SIP NMS support based on RFC 3842.

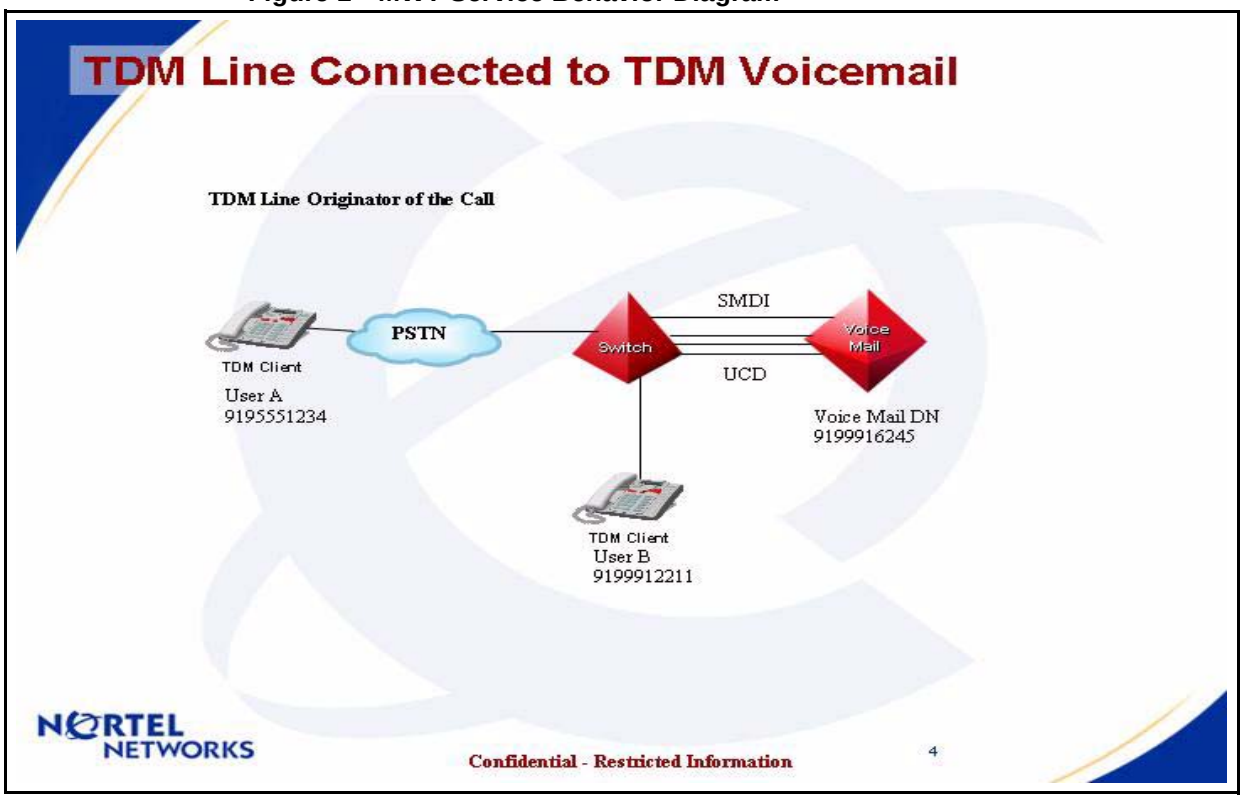
In the CS2K Core, NCAS link development is done under activity A00004500 in SN07. However, this development did not consider some internal drawback associated with Intelligent Network Access Point (INAP) signalling. Therefore, under this activity, the INAP drawback has been removed.

4.2.2 SIP NMS Support based on RFC 3842

The Message Waiting (MWT) service is a CS2K Core based service. The complete MWT service, includes Voicemail system (VM) to record voice messages and retrieve voice messages, communication link between CS2K Core and VM, the MWT service control in the CS2K Core, end user devices to provide MWT Indication (MWI) and CS2K Core based Redirection Services, such as Call Forward Do not Answer (CFD/CFDA) etc.

The following figure provides a pictorial view of how MWT service is provided to an end user and how an end user uses the service in traditional switching environment.

Figure 1 MWT Service Behavior Diagram



The following steps describe the functionality shown in Figure 1 above:

1. User A (In PSTN network) is calling User B (On serving End Office (EO))
2. User B does not answer (User B's CFDA is set to go to DN of VM). Call Forwarding happens and Call terminates to DN of VM.
3. VM answers the call and prompts user A for message. Message is recorded by User A. User A exits and call clears.
4. VM sends a turn on notification to EO for providing MWT functionality to User B.
5. EO sends appropriate message to User B's device to turn on the MWT Indication (MWI).
6. User B finds MWI, initiates call request for retrieval (CRR) functionality. The call terminates to DN of VM.
7. VM answers the call and prompts User B for User ID and Password for authentication. User B enters appropriate details. The VM play the message from User A to User B. User B can continue to interact with VM.
8. VM sends a turn off notification to EO for providing MWT functionality to User B.
9. EO sends appropriate message to User B's device to turn off the MWI.

The above functionality provides support for the traditional MWT service along with a traditional Voice Mail system. Increasingly, number of customers are deploying the VM connection with the CS2K Core or equivalent class 5 switches in a network mode. In this case, the customers have to maintain only one VM for mutiple customers servred via different class 5 switches (including CS2K). The existing software in CS2K Core already provide this service using NMS based on GR-866_core using SS7 network.

Due to advancement of Unified Messaging (UM) which combines all type of mail messages (e.g. Voice Message, E-mail, Paging etc.) and Voice over Internet Protocol (VoIP), an increasing emphasis to provide same functionality using SIP based on RFC 3842.

The MWT functionality to CS2K Core based SIP lines is developed under SIP lines development plan (Please refer to actid A0000 - for CS2K Core design, actid A0000 - for CS2K GWC design and actid A0000 - for CS2K SS design). The communication between CS2K SS and SIP Line is based on the RFC 3842.

Deployment of the SS7 network is expensive proposition in the VoIP network. While SIP based on RFC 3842 can provide similar network capability using SIP messages between two CS2K or a CS2K and SIP compliant remote node (e.g. MCS). This feature develop necessary software in CS2K SS to support RFC 3842 based message waiting SIP messages and expands existing NMS software in CS2K Core to use the SIP network to provide network message waiting service to/from remote CS2K or SIP compliant remote node.

This feature does not cover development needed in SIP clients, SIP compliant remote node and SIP compliant VM.

Based on the converged network needs and support for multiple interfaces following end user devices are supported:

- Traditional Phones (e.g POTS, RES, IBN, KSET etc.)
- CICM IP sets
- Traditional Lines off of a remote switch
- Traditional Lines off of a remote SIP domain
- Traditional Lines off of a PBX
- SIP lines served by MCP 5100/5200.

Also, following interfaces to a message server (Voicemail) system are supported:

- Traditional SMDI and UCD/HUNT group to VM.
- Traditional VM using public SS7 network for NMS.
- Traditional VM using SIP NMS based on RFC 3842.
- SIP NMS based on RFC 3842 for MCP 5100/5200 platform.

The combination of above user devices and VM interfaces are supported with following interoperatibility limitations.

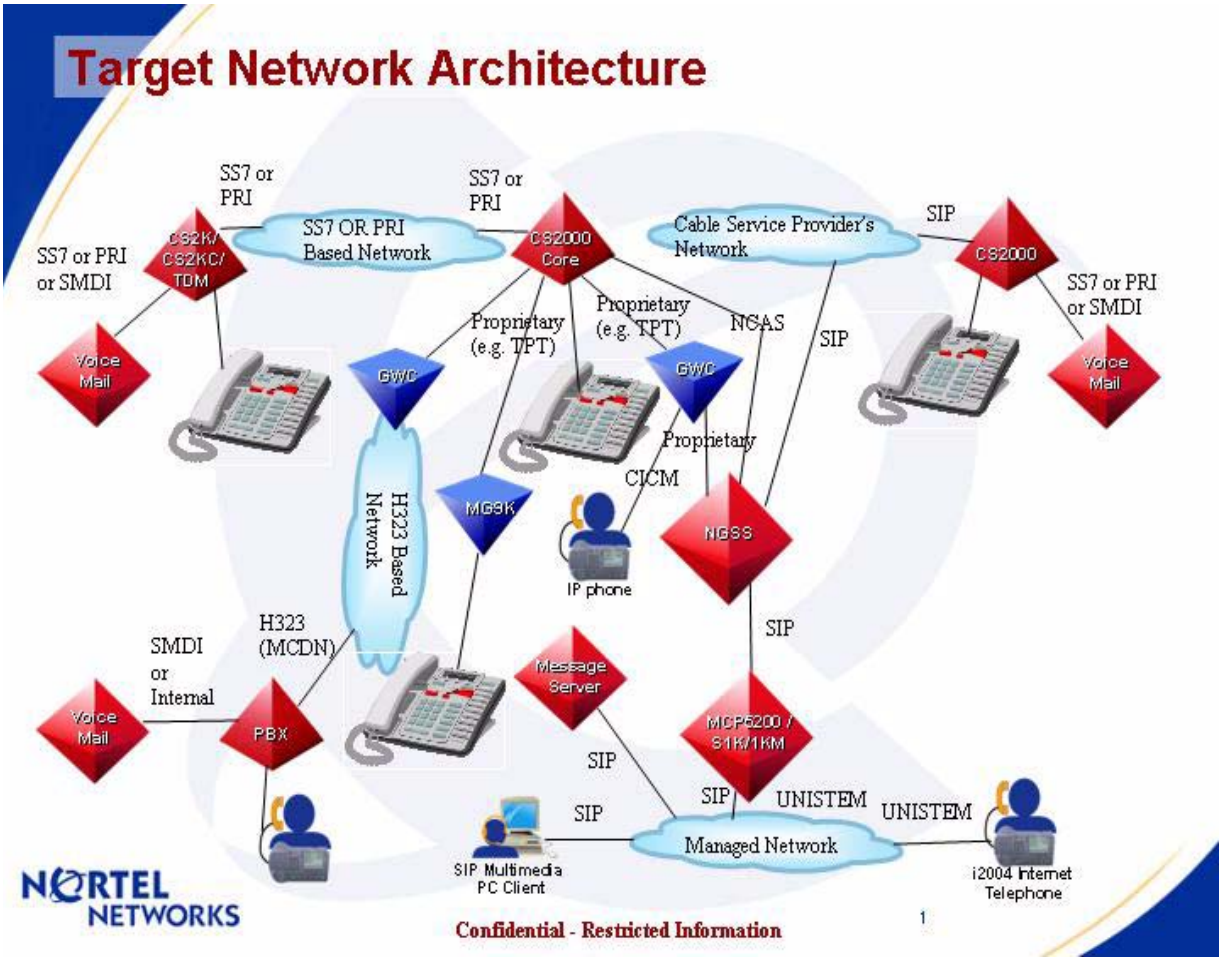
The design is generic and based on RFC 3842 standards, we are unable to test every possible interoperatibility using different handware and different vendor equipments. Therefore, we can only be able to claim the support for the tested networks. In order to make other hardware and different vendor equipment supported, proper interoperatibility testing must be done in Nortel approved interoperatibility lab. After the complete testing, appropriate support will be provided for them.

For Cable network support we need a design lab with appropriate Media Terminal Adaptors (MTAs). For design testing, no such lab identified yet. Without this testing, we can not claim the compatibility with cable specification for this feature.

4.2.3 Target Network Architecture

The feature develops a converge network architecture. In this architecture of the Message Waiting the VM or Message Server (MsgSrv) can resides any network and the user device can resides in any network. The communication required for MWT service is supported by this architecture. The following figure (Figure 2) is pictorial representation of the target architecture.

Figure 2 Target Architecture



With this development, MWT is provided across the different type of networks within Service Provider's network. The following are the advantages to the service provider:

- Support of MWI on user's choice of device
- Consolidation of the VM system in service provider's network
- Converged network support
- MWI to SIP clients or S1K/1KM

Other topologies and how MWT service provided are described in "Supported Configurations" on page 65.

4.2.4 Supported Configurations

The connection and communication bases the supported configurations are separated in two catagories. 1) Configurations of Voicemail or MsgSrv systems and 2) Configurations of Lines or clients.

The configurations described here are specific to MWT service and VM communications for MWT service. These configurations assumes that the call related communications and signalling are provoided prior to the MWT service and exists in the given configuration.

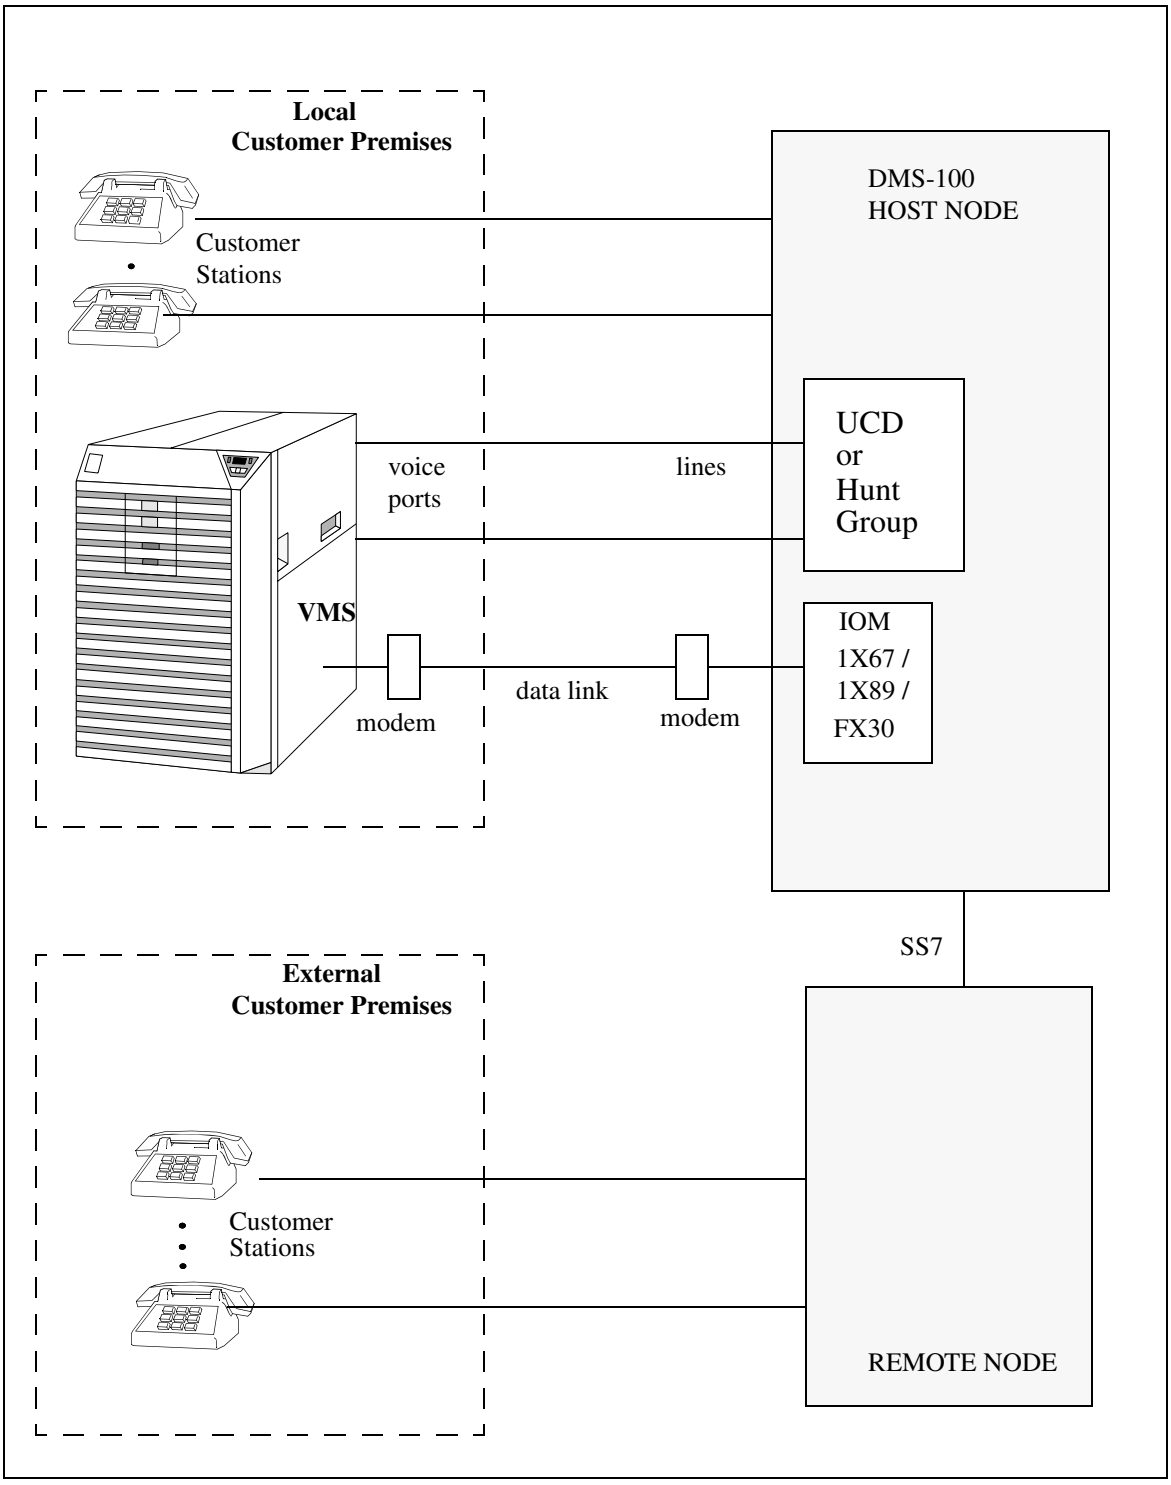
4.2.4.1 Configurations of Voicemail or MsgSrv Systems

The following configurations are separated by the protocol used for communication between CS2K and VM system:

4.2.4.1.1 Traditional VM communication using UCD/HUNT group and SMDI link

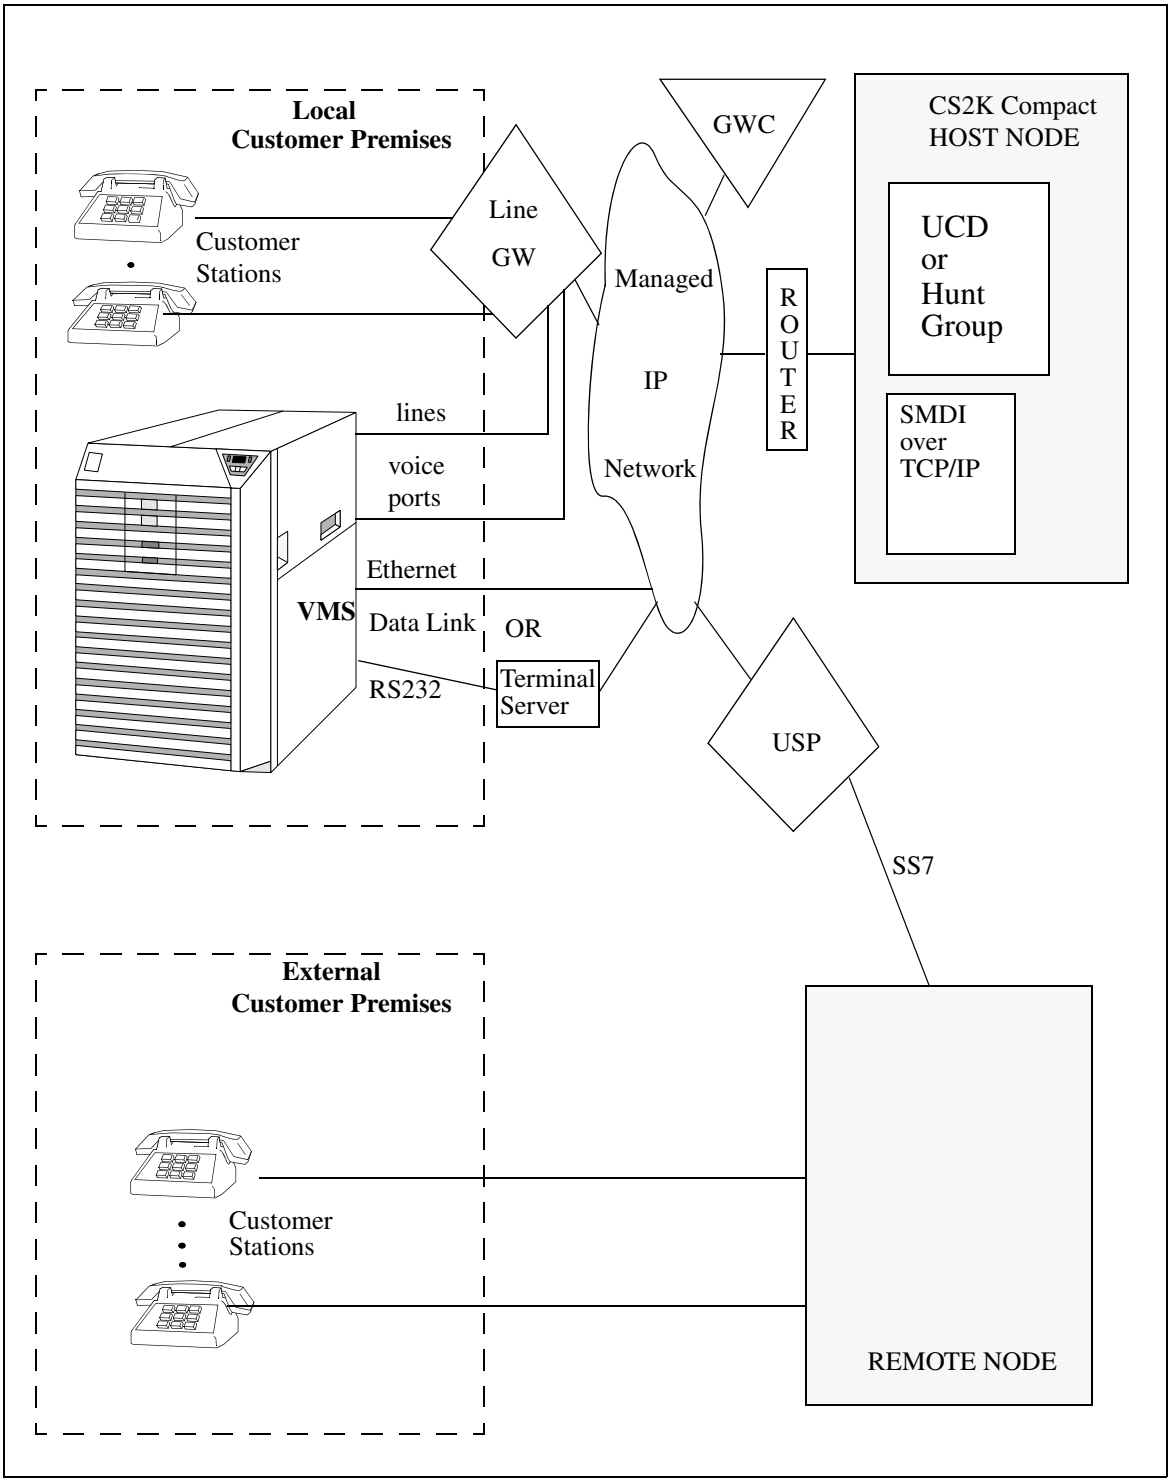
This is an existing and supported configuration in CS2K/DMS. For details on this configuration, please look in the NTP 297-2051-104- SMDI Setup and Operation. The following figure is a generic view of this configuration in DMS:

Figure 3 Simple VM Configuration in DMS



The data link in above Figure 3 is based on SMDI specifications described in the GR-283-Core. The following figure provides simple VM configuration in the CS2K Compact:

Figure 4 Simple VM Configuration is CS2K Compact



In Figure 4 , the communication between the CS2K Compact and VM is SMDI based on GR-283-Core. However, the transport medium is TCP/IP. The

details of this configuration can also be found in the NTP 297-2051-104 - SMDI Setup and Operation.

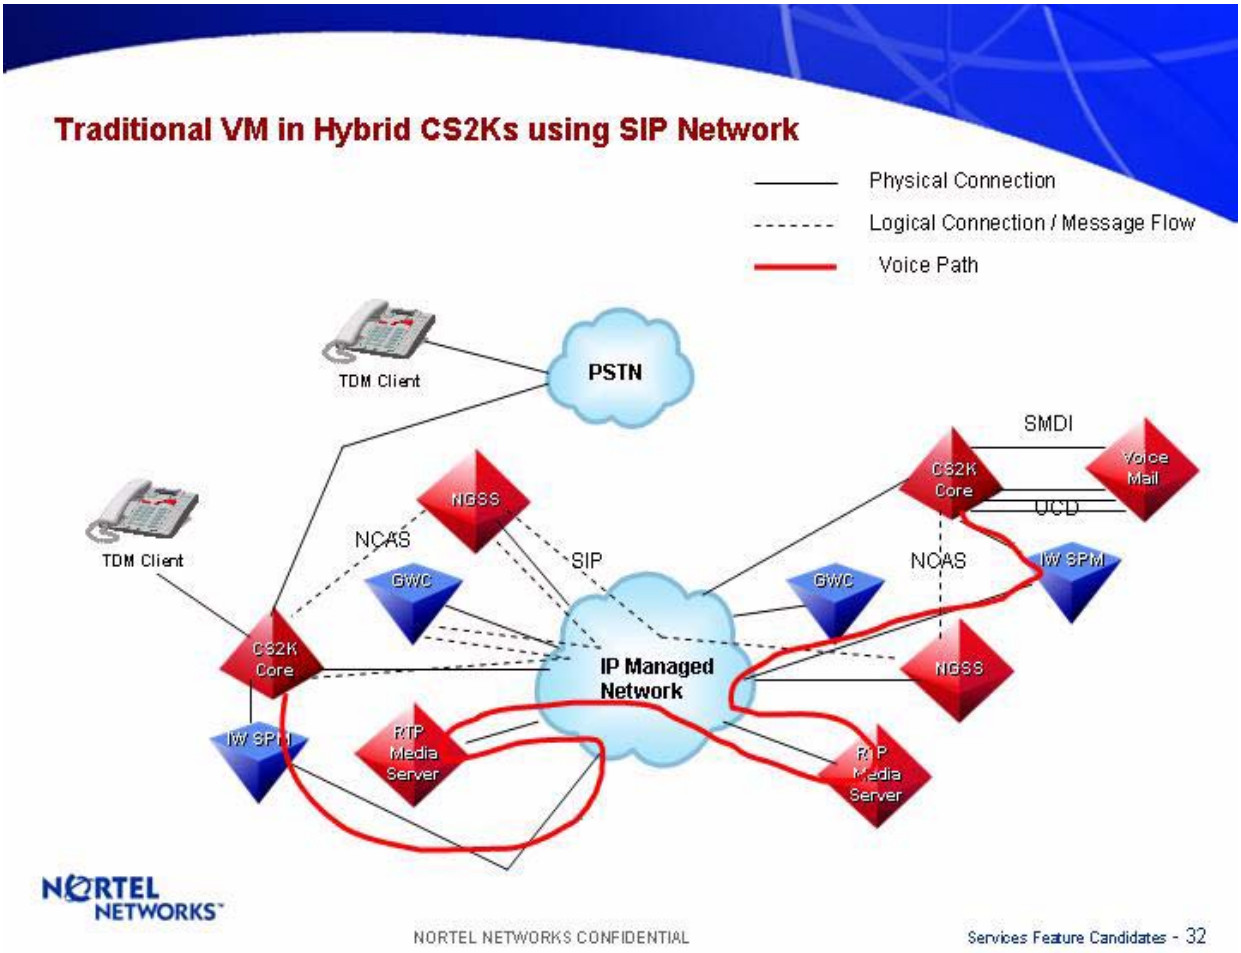
4.2.4.1.2 Network VM communication using SS7 network

The Figure 3 and Figure 4 also describe the configuration of the VM communication using SS7 network between host node and remore node. For details, please see NTP 297-2051-104 - SMDI Setup and Operation; and NTP 297-8021-350v13 - North American Translation Guide Volume 13 of 25.

4.2.4.1.3 Traditional VM communication using SIP network

This configuration, the VM is a traditional VM connected to one CS2K via SMDI and UCD/HUNT group. The line is on another CS2K. The RFC 3842 based SIP messages are used between two CS2K to pass MWI information for NMS.

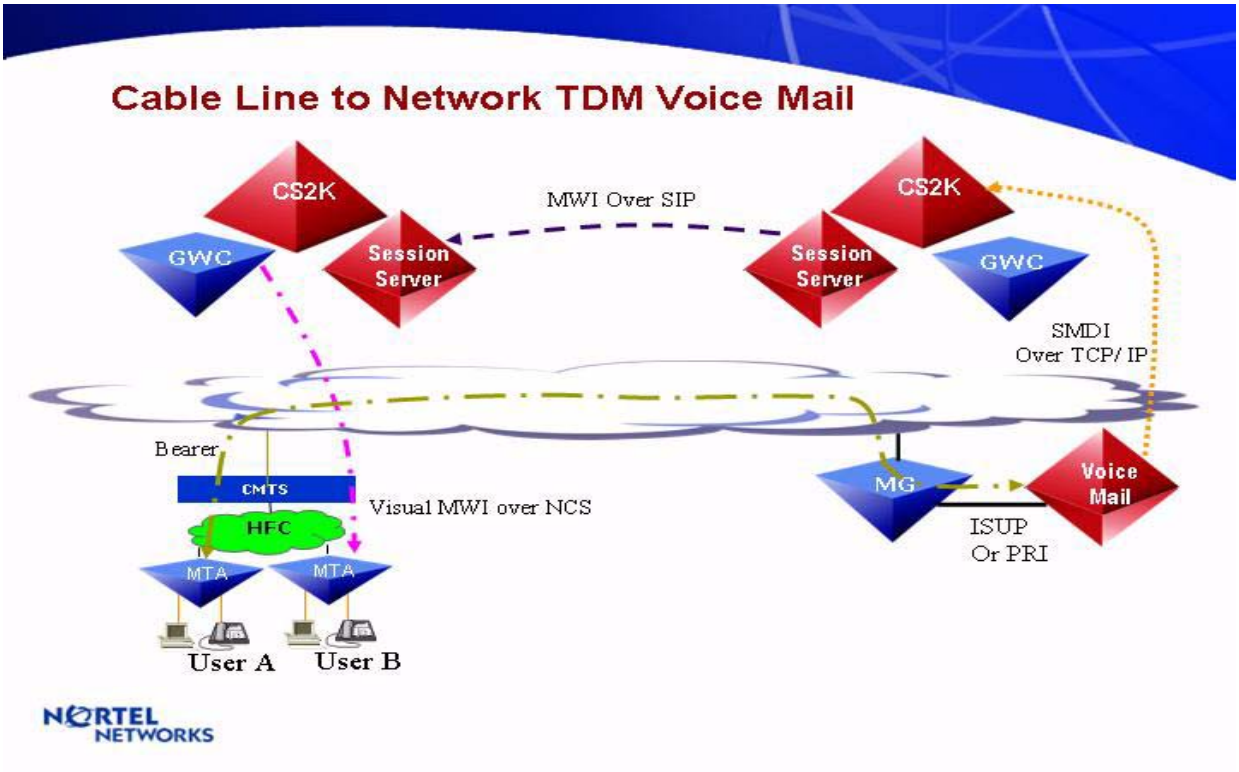
Figure 5 Traditional VM communication using SIP network



4.2.4.1.4 Network VM communication using SIP for Cable Service Providers

In cable service provider network, the VM is connected to a CS2K compact as described in previous section. However, the communication between two CS2K Compact is based on the managed IP network using SIP signalling.

Figure 6 VM in Cable Network

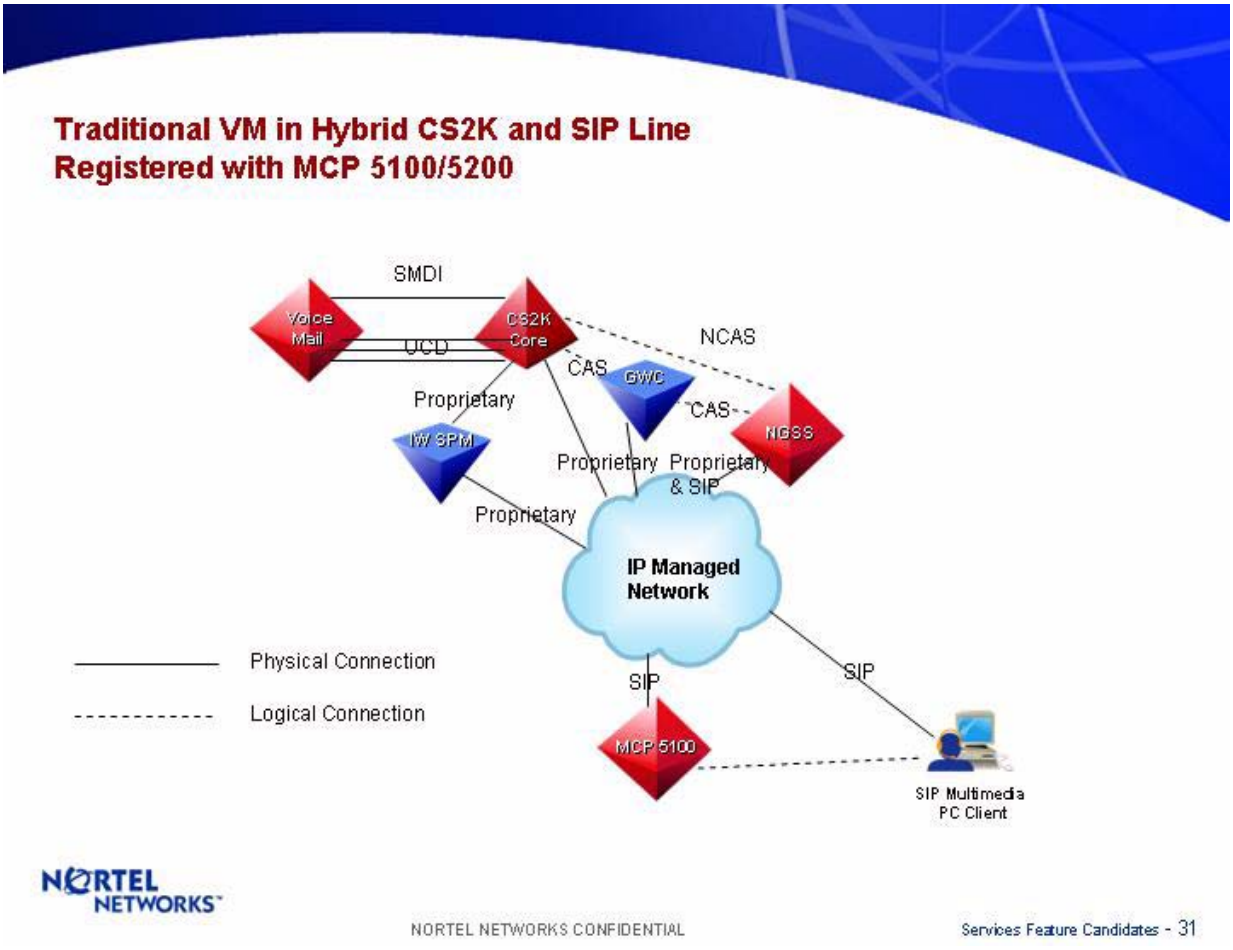


Note: The complete interoperatibility and compliance depends on the availability of the design lab. This configuration is quite similar to configuration describe by Figure 5 in previous section. The only major difference is the usage of MTA and conformance testing for cablelab specifications.

4.2.4.1.5 VM support for MCP 5100/5200 Platform using SIP network

This configuration, the VM is a traditional VM connected to one CS2K via SMDI and UCD/HUNT group. The SIP line is registered with the MCP 5100/ 5200 platform and SIP line is served by the traditional VM. The CS2K is sending RFC 3842 defined SIP messages to MCP 5100/5200 platform to provide network based MWI service.

Figure 7 VM support for MCP 5100/5200 using SIP network



4.2.4.2 Configurations of Lines or clients

The details of these configurations (datafill and setup) are described in the CN section of the feature. The following configurations are separated by the protocol used for communication between CS2K and line/client:

4.2.4.2.1 Lines connected via LCM/XPM

The phone line which is connected via LCM/XPM using PSTN network to the host node are supported today. In case of the SIP VM, these type of lines are considered as non-SIP lines and appropriate additional configuration is required in the Session Server.

4.2.4.2.2 Lines connected via Gateways

The phone lines which are connected via a MG9000 behave the same as traditional line connected to the CS2K via LCM/XPM. There is no change anticipated in this configuration. The CICM lines which are connected via an

IP gateway behave the same. There is no imapct to thier setup and operation. In case of the SIP VM, these type of lines are considered as non-SIP lines and appropriate additional configuration is required in the Session Server.

4.2.4.2.3 Lines connected to a remote node

The lines connected to a remote node (e.g. PBX, another switch, MCP etc.) are considered as networked lines. For these lines network message waiting (NMS) service is provided. The CS2K does not store any data associated with these remote lines.

4.2.4.2.4 Media Terminal Adaptor

The media terminal adaptor is used in the cable network to provide media (voice) services. From the CS2K perspective, the media terminal adaptor is same as a line in the CS2K supported via gateways and gateway controller. The MWT service is provided to the Media Terminal Adaptor same way as it is provided to lines connected via gateways.

> ***Note:*** The complete interoperatibility and compliance depends on the availability of the design lab. The availability of MTA will allow us to perform this cable network requirement. However, it will not be tested, if no lab or MTA available. If we assume that the MTA cable line is another line in the CS2K and behave same way as any other line with MWT service assignment, than this design will support the MTA.

4.2.4.2.5 Single Physical Line with Multiple VM Access

Current design of MWT service in the CS2K does not restrict a single physical line to have access to multiple VM systems. With this design, there is no change to such support. The support is provided using the datafill of the Call Forwarding on the single physical line. The following example explain how this works:

Line B is a KSET line with two different DN keys and has MWT service assigned to it.

The first key's DN is datafilled with call forwarding busy (CFB) and call forwarding do not answer (CFD) and call forwarding number to DN of VM 1.

The second key's DN is datafilled with call forwarding busy (CFB) and call forwarding do not answer (CFD) and call forwarding number to DN of VM 2.

Now let say first call to DN Key 1 encounters busy condition and forwards to the VM 1. The VM 1 records the message and send a message to CS2K to turn MWT light on for the DN Key 1. The MWT light is now lit for the first message from VM 1.

During the first call, a second call come to the DN key 2 and encounters no answer condition and forwards to the VM 2. The VM 2 records the message and send a message to CS2K to turn MWT light on for the DN Key 2. The request is now enqueued for the VM 2.

When user of Line B retrives the message from the VM 1, the MWT light will remain lit for the second message.

Please note that the MWT request from each VM will be treated as two separate requests in the MWT service.

4.2.4.2.6 Multiple Lines with Single VM Access

The multiple lines in a given CS2K are supported by a single VM. In this case the VM has each line provisioned as individual user. This is already supported functionality. This functionality is not changed by this feature.

If VM is capable to provide multiple MWT messages for multiple lines in a single mail box than it is also suppored because for each line CS2K receive a MWT message.

4.2.4.2.7 Multiple Lines with Multiple VM Access

This configuration is also supported in current design. The following example describes how this is supported.

Line A is a RES line with MWT service and datafilled with CFB and CFD forwarding to DN of VM 1. The VM 1 is on a remote node.

Line B is an IBN line with MWT service and datafilled with CFB and CFD forwarding to DN of VM 2. The VM 2 is on host node.

Line C is a SIP Line with MWT service and datafilled with CFB and CFD forwarding to DN of VM 3. The VM 3 is a SIP VM. The Line C is not registered.

Originator A calls Line A and Line A is busy. The call forwards to VM 1 on remote node. The VM 1 records the message from Originator A. The remote node sends a MWT message to the host node. The request of network MWT is now queued to Line A from VM 1.

Originator B calls Line B and Line B is busy. The call forwards to VM 2. The VM 2 records the message from Originator B. TheVM 2 sends a MWT message to the host node. The request of local MWT is now queued to Line B from VM 2.

Originator C calls SIP Line C and SIP Line C is not registered. The call forwards to VM 3. The VM 3 records the message from Originator C. TheVM

3 sends a MWT message to the host node. The request of network MWT is now queued to Line C from VM 3. The MWT notification is not sent to the Line C because it is not register. When the user of Line C sends a subscribe message for MWT after registration, the CS2K sends the current status of the MWT service in the CS2K to the line C.

4.2.5 Sample Message Details for SIP

The message details are based on the SIP Line configuration described above.

Step 1: The SIP Line SUBSCRIBE for MWT service.

Figure 8 SIP Line Register with CS2K - SUBSCRIBE Message

Step 6: CS2K sends NOTIFY message.

Figure 28 CS2K sends NOTIFY Message

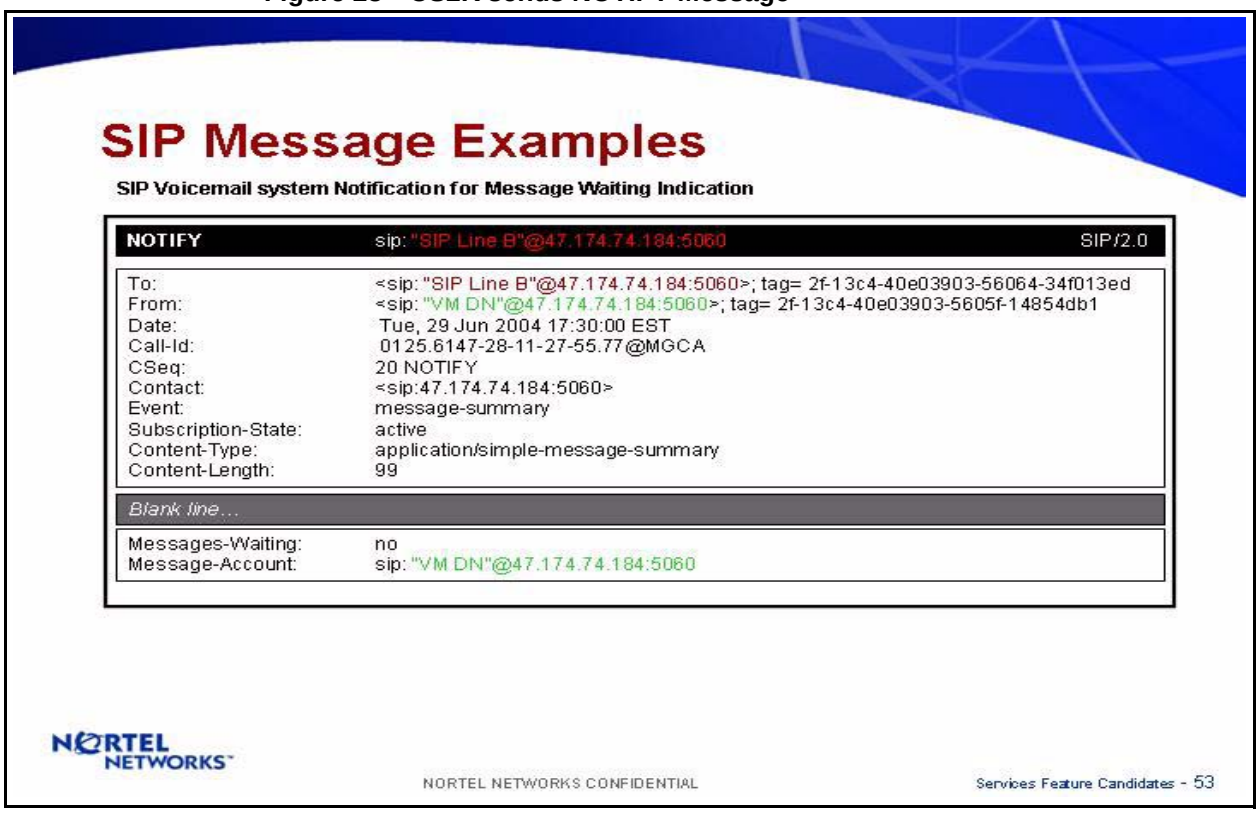

Figure 29 SIP Line - 200 OK Response

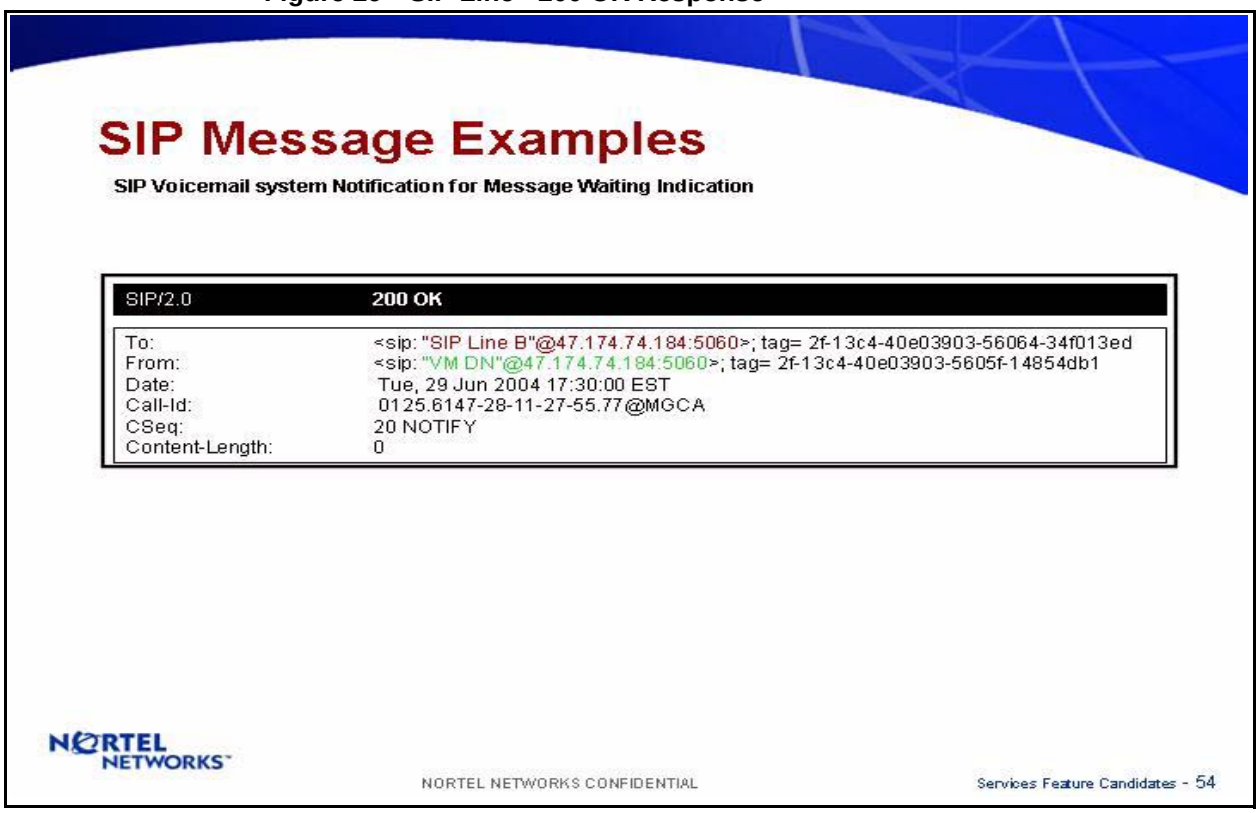

4.2.6 SOC Control

The new functionality is controlled by a SOC. This is a state controlled SOC. The following SOC is developed for this feature:

MDC00078 - NMS Over IP (SCTP)

4.3 Hardware Requirements or Dependencies

This feature uses the existing hardware of CS2K Core and Session Server. The Session Server provides standardized interface to SIP. Therefore, all 3rd party hardware and Voicemails are directly supported.

There is no new hardware dependency or requirement for this feature.

4.4 Software Requirements or Dependencies

The development depends on following 3rd party software currently exists in respective platform:

- SIP Stack from RADVISION in Session Server

4.5 Limitations and restrictions

The following limitations and restrictions apply to the feature:

- The NMS service sends MWI ON/OFF for the remote lines. It is assumed that the remote node or SIP Client will provide appropriate indication to end user for the MWI. The MWI indication can not be enforced.
- The Call Request Retrieval (CRR) functionality can not be invoked as second leg of Three way call (TWC). This limitation is for fraud prevention.
- The Call Request Retrieval (CRR) functionality can not be invoked as second or subsequent leg of a conference (CNF) call. This limitation is for fraud prevension.
- The MWT functionality is only provided to multiple appearance directory number (MADN) primary member.
- The MWT functionality is only provided to HUNT group primary member only.
- All existing MWT and NMS service limitations apply to this feature.
- The optional data defined in the RFC 3842 are not supported by this feature due to limited design scope. The support for the optional data can be developed in future releases.
- The direct SIP VM communication is not tested. Therefore, support for non-SIP lines using SIP VM can not be verified nor tested.
- In cases where a Line connected to a CS2K, the VM connected to a remote node (e.g. MCS) via SIP network and if G729 compatible codec is used for interconnect voice paths than remote node or device must support RFC 2833 for out of band DTMF signalling.
- When the line is connected to a remote node (e.g. MCS) via SIP network, VM is connected to a CS2K and if G729 compatible codec is used for interconnect voice paths than remote node or device must support RFC 2833 for out of band DTMF signalling.
- The design is generic and based on RFC 3842 standards. Testing limitations does not allow to test every possible interoperatibility using different handware and different vendor equipments in a network. Therefore, only tested network configurations are supported. In order to make other hardware and different vendor equipment supported, proper interoperatibility testing must be done in Nortel approved interoperatibility lab. After the complete testing, appropriate support will be provided.

4.6 Interactions

The service is controlled by the CS2K Core. The Session Server and GWC only provides access to various networks and protocol conversions. Therefore, CS2K Core interactions are applicable to this service.

The existing MWT and NMS service software is used for the development. Therefore, all existing interactions are apply to this expansion of service. There is no new interaction anticipated at the time of this writing.

4.7 Glossary

Term	Description
MWT	Message Waiting
MWI	Message Waiting Indication

5: Functional Description (FN): A00007547

5.1 Feature name

A00007547: SIP Lines Core Call Processing Support

5.2 Description

This activity provides initial CS2K support for SIP (Session Initiation Protocol) lines basic call for SIP agents that interface to the CS2K via the GWC and CS2K Session Server. This includes the following components:

- Support for multiple call appearances for DPL lines
- CS2K call processing support for SIP basic call including signalling interface with the TPT in the GWC.

5.2.1 Multiple Call Appearances

Support for multiple call appearances relies on a new pool of resources (virtual terminal identifiers). This new pool has OMs and logs associated with it.

The new OM group DPLOM, has registers:

- DPLFNVA, DPLFBAL, DPLFREB, DPLRLOS
- DPLRCAL, DPLUSE, DPLFRE, DPLNOA, DPLNOD

DPL logs: DPL100, DPL101

The remainder of this section explains the rationale for these items and how they will be used when multiple call appearances are supported for SIP lines on the CS2K.

SIP allows devices to make multiple simultaneous call attempts, and actively engage in multiple simultaneous calls. The maximum number of such calls will be limited on a per-line basis, as part of the DPL SERVORD option, as described in feature A00008556. In order for the CS2K to handle these lines in a manner that preserves the way various line options work (as much as possible) and that makes efficient use of CS2K resources, a new resource pool is created. This section describes the resource pool and how it is controlled and monitored.

The new resource pool consists of “virtual terminal identifiers” (VIDs). VIDs are an existing resource on the CS2K. One VID is required for each appearance

of a SIP line in a CS2K call. The pool will be sized to the total of the maximum call appearances of all DPL lines (from the DPL SERVORD option) but capped at twice the maximum number of simultaneous calls (existing office parameter NCCBS in OFCENG).

5.2.1.1 Resource pool monitoring

There is a new OM group (DPLOM) defined that contains pegs and usage measurements of the resource pool. The registers are:

- DPLUSE - usage register (100 sec sampling, with extension register) that tracks the number of VIDs in use by call processing
- DPLFRE - usage register (100 sec sampling, with extension register) that tracks the number of VIDs on the resource pool free list.
- DPLNOA - peg register (with extension) that indicates the number of allocations from the resource pool.
- DPLNOD - peg register (with extension) that indicates the number of deallocations to the resource pool.
- DPLFNVA - peg register that indicates the number of times that a failure to allocate a VID happened because the resource pool free list was empty.
- DPLFBAL - peg register that indicates the number of times that a failure to allocate a VID happened because the resource pool free list was unavailable due to rebalancing (part of the rebuild process).
- DPLFREB - peg register that indicates the number of times that a failure to deallocate a VID happened (resulting in a “lost” VID) because the resource pool free list was being rebuilt.
- DPLRLOS - peg register that indicates the number of “lost” VIDs that were recovered .
- DPLRCAL - peg register that indicates the number of VIDs that were in use by call processing, but were not returned to the resource pool free list.

5.2.1.2 Resource pool recovery

As with any resource pool, there are recovery mechanisms. There is an audit which will recover “stranded” VIDs, that is, VIDs which are no longer in use, but have not been returned to resource pool free list. There is also a mechanism which detects corruption in the resource pool free list, and reconstructs it. A log will be output at the beginning of that reconstruction, and another at the end (DPL100 and DPL101, respectively).

5.2.2 Call Processing

The call processing component of this feature has very little customer visible impact to functionality. From the CS2K’s perspective, calls to and from DPL lines will function in the same manner that calls to and from standard IBN or RES lines function. Other than the VID allocation described in the previous

section, the CS2K will provide very little indication that the end user is in fact a SIP client.

The entire call progresses as a typical IBN or RES line call would progress. This will include any standard OMs and logs that apply to IBN and RES lines. Additional OMs and logs related to the DPL VIDs may be produced as described in the previous section.

The main exception to the IBN/RES call processing model is the fact that the DPL SIP line can have multiple call sessions active at any given time. This introduces 2 new concepts: 1) A maximum number of call appearances per DPL line can be defined, and 2) The presence of certain options on the line can dictate whether or not multiple terminations are allowed when the line is "busy".

5.2.2.1 Maximum Call Appearances

Each DPL SIP line defined in the core will be provisioned with a suboption called MAX_CALL_APPEARANCES. (See A00008556 for more information on provisioning the DPL line.) MAX_CALL_APPEARANCES will define the total number of VIDs that can be allocated for the line. Therefore, the total number of incoming and outgoing calls that involve the DPL line cannot exceed the value of MAX_CALL_APPEARANCES for that line.

Once the call appearance limit has been reached, any incoming call attempts will receive BUSY treatment, and any outgoing call attempts will receive NOSR (No Software Resources) treatment.

5.2.2.2 Allow Busy Terminations

The ability of a DPL line to have multiple active call sessions introduces some interaction problems with common CS2K features. For example, standard call waiting has no useful purpose if multiple calls can already be terminated on a DPL line.

To solve this problem, the concept of ALLOW_BUSY_TERMINATIONS is introduced. ALLOW_BUSY_TERMINATIONS is an internal bool that will be stored for every DPL line in the CS2K.

When the bool is set to N, incoming calls will not be presented to the DPL line if there is already at least one active call in progress. These calls will receive BUSY treatment instead. When the bool is set to Y, the only restriction on incoming calls being presented to the DPL line is the value of MAX_CALL_APPEARANCES.

Outgoing calls originated by the DPL line will not be restricted by the ALLOW_BUSY_TERMINATIONS bool at all.

ALLOW_BUSY_TERMINATIONS is not intended to be a provisionable value. It will be stored internally, and altered based on the addition or removal of certain options on the DPL line. For example: Initially the bool will be set to N, meaning that if one call is active, all subsequent incoming calls will receive busy treatment. The addition of the CWT option on the DPL line will cause the system to flip the internal bool to Y, and thus additional call terminations will be allowed as per the CWT feature function.

5.3 Hardware Requirements or Dependencies

5.4 Software Requirements or Dependencies

5.5 Limitations and restrictions

The DPL option will only be assignable to IBN and RES LCCs.

5.6 Interactions

Keyset and ISDN lines also make use of VIDs, but do so strictly based on provisioning. VIDs used for keyset and ISDN lines are separate from VIDs used in the resource pool defined by this activity. Thus, provisioning of keyset and ISDN lines will decrease the number of VIDs available for the resource pool defined by this activity, and vice versa.

5.7 Acronyms

Acronym	Description
ACD	Automatic Call Distribution
CS2K	Call Server 2000
DPL	Dynamic Packet Line
GWC	Gateway Controller
IBN	Integrated Business Network Line Type
ISDN	Integrated Services Digital Network
MADN	Multiple Appearance Directory Number

Acronym	Description
RES	Residential Line Type
SCMP	Series Completion
SIP	Session Initiation Protocol
VID	Virtual Identifier

6: Functional Description (FN): A00007703

6.1 Feature name and Feature ID

A00007703 SDM/CBM Log Capacity & Robustness

6.2 Description

A00007703 is intended to increase the log-flow capactity from the DMS Core to the SDM or CBM. Currently, the log rate is 10 logs/second (sustained) and 20 logs/second (2-minute burst) from the Core to the SDM or CBM. The sustained and burst rates are to be increased to 40 logs/second.

The increase in log throughput will be handled through one or two means. Firstly, a stream-lined LOGDEVP process will be implemented for the SDM and CBM log device, SDM_LOGDEV01. Currently, each LOGDEVP process communicates extensively with its associated LOGSLAVE process. The stream-lined process will bypass LOGSLAVE, thus removing the involvement of the middle-man and the inter-process communications overhead associated with it. This enhancement requires only changes to the Core software.

Optionally[1], the messaging scheme used to send the Core logs to the SDM or CBM will be made more efficient. The protocol iscurrently being used to send only one log at a time from the Core to the SDM or CBM, but it is capable of sending multiple logs at once. The implementation will be changed on both the Core and the SDM/CBM sides to allow the handling of multiple logs per message, and thus increasing log throughput.

This feature affects only the SDM_LOGEV01 log device, which is specifically used to send Core logs to an SDM or CBM for storage, downstream processing, etc. No other log devices will be affected.

The types of logs being handled by SDM_LOGDEV01 will not change as a result of this feature.

Logs handled by SDM_LOGDEV01 will still be visible on the Core as per normal handling, such as through LOGUTIL buffers and DLOGs. The logs will still be available to other log devices as required.

No new logs will be introduced by this feature.

[1]This option will be exercised if the LOGSLAVE bypass functionality does not increase Core-to-SDM/CBM log throughput to 40 logs/second.

6.3 Hardware Requirements or Dependencies

There are no specific hardware requirements or dependencies for A00007703. The feature is applicable to any DMS Core hosting an SDM or CBM.

6.4 Software Requirements or Dependencies

There are no new software requirements or dependencies for A00007703.

6.5 Limitations and restrictions

There are no restrictions or limitations associated with A00007703.

6.6 Interactions

This feature does not have any end-user-visible interactions.

6.7 Glossary

Term	Description

SDM	SuperNode Data Manager

7: Functional Description (FN): A00007704

7.1 Feature name and Feature ID

A00007704: Table Access Manager Robustness

7.2 Description

This feature A00007704: Table Access Manager Robustness will allow the user/applications to make up to 5000 symbol changes and 1000 type info changes continuously without breaking the connection with SDM/CBM Table Access service. Prior to this feature, only less than 150 continuous DD changes were supported.

7.3 Hardware Requirements or Dependencies

None.

7.4 Software Requirements or Dependencies

The Table Access Service application is installed on the SDM/CBM and is in InSv state.

7.5 Limitations and restrictions

This activity does not prevent the SDM or CBM from re-downloading the Data Dictionary due to problems on the SDM/CBM side such as the DD file size exceeding 10 MB or the DD file being corrupted.

7.6 Interactions

None

8: Functional Description (FN) A00007814

8.1 Feature name and Feature ID

REX testing for MG9000 (Media Gateway 9000) from Element Manager - A00007814

8.2 Description

Routine Exercise (REX) of intelligent card pairs is being introduced in SN09 release to perform the diagnostics of the inactive card. During REX, the inactive card of a card pair will be diagnosed. Followed by the inactive card, REX is executed on the active card, after a SWACT is initiated on the active card which now becomes inactive.

The need for a REX test stems from the fact that the inactive card (standby card) may be prone to latent faults, as it does not get exercised on a regular basis. Exercising it in a way that an active side operates during normal operation will provide a means to detect dormant failures. Moreover, the impact of incorrect or failed operation is in itself a means of detecting problems. Thus REX tests improve fault coverage of hardware and software, repair can take place during off-peak hours and the system re-instated into service before peak hour begins.

User will be able to input the schedule for REX on a particular NE. Intelligent card pairs considered for REX on MG9000 are SCO/SCI/SCG (DCC), ITP and ITX cards. User will be able to see the progress of the REX on a particular NE from the REX GUI of Subnet View and on NE Desktop View. Success/failure of the operations in REX for a given NE are also logged.

2.2.1 REX Scheduling

REX NE option is provided in the configuration menu of Desktop view. On clicking the REX NE menu, REX GUI will be opened. User will be able to initiate REX on NE(s) using REX GUI. REX GUI contains options to Add, Remove, Suspend, Resume an NE for REX. User can perform the following from the REX GUI:

1. REX on an NE can be scheduled for a particular day, time from the GUI or can be executed immediately. Scheduling of REX is similar to that of Audit.

2. An option is provided to remove an NE for which REX is already scheduled. On removing the NE, if the REX is in progress, it would be suspended.

3. User can suspend the already scheduled REX.

4. User can resume the suspended REX.

5. User will be able to view the results/progress details of REX executed on the selected NE.

2.2.2 REX Results

During REX, inactive card of the intelligent card Diagnosed. The results of all these operations are logged and progress of REX is shown on the progress details field of the REX GUI. Progress details are also shown on the REX tab of NE Desktop View. Success/Failure of SWACT and diagnostics are displayed to the user as part of the progress details and also in the Logs.

8.3 Hardware Requirements or Dependencies

None

8.4 Software Requirements or Dependencies

None

8.5 Limitations and restrictions

1. REX will not be supported on ABI cards. ABI cards behave as master-slave and hence SWACT is not possible on ABI cards.

2. REX will not be supported on DS1 cards as they adhere to 1:N protection scheme.

3. Any swact on ITPs should be followed by a wait period of at least 1 minute prior to locking the newly inactive card. Until ready for service calculations are handled on the inactive, the possibility remains that an ITP newly swacted to, may give up activity, shortly after the swact (as it discovers its not truly capable of providing service)

4. A critical datasync fault on the inactive card must not block Rex from locking/diagnosing/unlocking the inactive. A corollary to this restriction is that the card pairs exhibiting CPU overload alarms (or cards subtending a card with CPU overload alarms, like an ITP below an overloaded Supercore) must not be REX tested. A log should be output if a card pair is skipped due to CPU overload.

9: Functional Description (FN): A00008090

9.1 Feature name and Feature ID

SBA: Alternate Scheduled Closure of Billing Files: A00008090

9.2 Description

This feature facilitates the closure of billing files at the scheduled Interval as specified in the Stream Configuration and providing an additional functionality of Resetting the DIRP Billing File sequence number at Midnight. This feature does not impact the existing functionality of file closure based on time and other mechanisms like file closure based on file size or number of records in a file.

With this feature, all the open billing files are rotated exactly at scheduled interval without any drift or delay. Irrespective of the opening time of the billing File, the closure will take place at the exact scheduled interval. For e.g. if the scheduled interval for the ‘ Scheduled File Closure time options’ is ‘6 Hour’ then for the time frame 00:00 to 06:00,all the billing files which are in the open state will get closed at 06:00. In the time frame 06:00 to 12:00, all the billing files which are in the open state will get closed at 12:00. Similarly next file closure will be at 18:00 and 00:00 respectively.

If the billing files are closed by any other criteria such as BSY of SBA or issue of ‘closec’, prior to the scheduled rotation then additional file rotation occurs without impacting the scheduled closure of the next file. In the above example suppose that a closec command is issued for the scheduled stream at 04:00, but still the next file closure will happen at 06:00, if any open file exists.

This feature is introducing a new option in the Stream Configuration to schedule closure of billing files without any drift or delay. This option is mutually exclusive with the option of ‘Files Closure based on a time limit’ which means users can only turn on either ‘Files closed at scheduled intervals from midnight’ or ‘Files Closure based on a time limit’, but not both.

The functionality of file closure at scheduled intervals from midnight can be enabled at the time of configuring a Stream or at the time of changing the configuration of an existing stream. In the latter case, the functionality will be activated only for the billing files which are opened after enabling the functionality. Bsy/Rts of SBA application is not required to activate this functionality.

Following are the Options for the file closure of billing files at scheduled intervals from midnight.

1) Close billing files every 24 hours

2) Close billing files every 12 hours

3) Close billing files every 6 hours

4) Close billing files every 2 hours

5) Close billing files every 1 hour (Default Schedule Time)

6) Close billing files every 30 minutes

7) Close billing files every 15 minutes

7) Close billing files every 10 minutes

8) Close billing files every 5 minutes

Reset DIRP Sequence Number at Midnight:

This feature provides a facility to reset the DIRP Billing File sequence number at midnight. The first DIRP billing file which is opened after midnight (00:00 Hr) will have a sequence number 00, if there is no other file exists with the same name. If the same filename exists then increment the sequence number and rename the file with that Sequence Number.

This is introducing a new option in the Stream Configuration to enable the functionality of 'Reset DIRP Sequence Number at Midnight'. This option is mutually exclusive with the option of 'Files renamed with close date' which means users can only turn on either 'Files renamed with close date' or 'Reset DIRP Sequence Number at Midnight', but not both.

9.2.1 Desired Behavior of 'file closure based at scheduled intervals from midnight' with Respect to the Daylight Saving Time:

Since the proposed design uses RWTime, the 'file closed based at scheduled intervals from midnight' behaves in the similar way which is explained below with the help of an example.

Note: In the below examples consider that files are not closed by any other criteria such as BSY of SBA or closing the file with the command 'closec' or any other criteria other than the scheduled rotation.

Considering the US/Eastern TimeZone .

CASE1: On 04 April 2004, when Time Changes from 01:59:59 -> 03:00 (Time changes from EST to EDT)

Scheduled Interval : 05:00 Mins

SBA closes the file at intervals 00:05 hr, 00:10 hr,...,01:50 hr,01:55 hr(EST),03:00 hr(EDT),03:05 hr(EDT),...,23:50 hr,23:55 hr,00:00 hr.

Scheduled Interval : 10:00 Mins

SBA closes the file at intervals 00:10 hr, 00:20 hr,...,01:40 hr,01:50 hr(EST),03:00 hr(EDT),03:10 hr(EDT),...,23:40 hr,23:50 hr,00:00 hr.

Scheduled Interval : 15:00 Mins

SBA closes the file at intervals 00:15 hr, 00:30 hr,...,01:30 hr,01:45 hr(EST),03:00 hr(EDT),03:15 hr(EDT),...,23:30 hr,23:45 hr,00:00 hr.

Scheduled Interval : 30:00 Mins

SBA closes the file at intervals 00:30 hr, 01:00 hr,01:30 hr (EST),03:00 hr(EDT),03:30 hr(EDT),...,23:00 hr,23:30 hr,00:00 hr.

Scheduled Interval : 01:00 Hrs

SBA closes the file at intervals 01:00 hr(EST),03:00 hr(EDT),04:00 hr(EDT),...,22:00 hr,23:00 hr,00:00 hr.

Scheduled Interval : 02:00 Hrs

SBA closes the file at regular intervals 03:00 hr (EDT), 04:00 hr (EDT),06:00 hr,...,20:00 hr,22:00 hr,00:00 hr.

Scheduled Interval : 06:00 Hrs

SBA closes the file at intervals 07:00 hr (EDT), 12:00 hr ,18:00 hr,00:00 hr

Scheduled Interval : 12:00 Hrs

SBA closes the file at intervals 13:00 hr (EDT) and 00:00 hr

Scheduled Interval : 24:00 Hrs

SBA closes the file on April 5 2004(next day) at 01:00 hr and 00:00 hr

CASE 2: On 31 October 2004, when Time Changes from 01:59:59 -> 01:00 (Time changes from EDT to EST)

Scheduled Interval : 05:00 Mins

SBA closes the file at intervals 00:05 hr, 00:10 hr,...,01:50 hr,01:55 hr(EDT),01:00 hr(EST),01:05 hr(EST),...,23:50 hr,23:55 hr,00:00 hr

Scheduled Interval : 10:00 Mins

SBA closes the file at intervals 00:10 hr, 00:20 hr,...,01:40 hr,01:50 hr(EDT),01:00 hr(EST),01:10 hr(EST),...,23:40 hr,23:50 hr,00:00 hr.

Scheduled Interval : 15:00 Mins

SBA closes the file at intervals 00:15 hr, 00:30 hr,...,01:30 hr,01:45 hr(EDT),01:00 hr(EST),01:15 hr(EST),...,23:30 hr,23:45 hr,00:00 hr.

Scheduled Interval : 30:00 Mins

SBA closes the file at intervals 00:30 hr, 01:00 hr,01:30 hr (EDT),01:00 hr(EST),01:30 hr(EST),...,23:00 hr,23:30 hr,00:00 hr.

Scheduled Interval : 01:00 Hrs

SBA closes the file at intervals 01:00 hr(EDT),01:00 hr(EST),02:00 hr(EST),...,22:00 hr,23:00 hr,00:00 hr.

Scheduled Interval : 02:00 Hrs

SBA closes the file at intervals 01:00 hr (EST), 02:00 hr (EST),04:00 hr,...,20:00 hr,22:00 hr,00:00 hr.

Scheduled Interval : 06:00 Hrs

SBA closes the file at intervals 05:00 hr (EST), 06:00 hr ,12:00 hr,18:00 hr,00:00 hr

Scheduled Interval : 12:00 Hrs

SBA closes the file at regular 11:00 hr (EST) 12:00 hr and 00:00 h**r**

Scheduled Interval : 24:00 Hrs

SBA closes the file on 31st October 2004 at 23:00 hr and 00:00 hr

9.2.2 Desired Behavior of 'Reset DIRP Sequence Number at Midnight' with Respect to the Daylight Saving Time:

The functionality 'Reset DIRP Sequence Number at Midnight' does not have any impact if the time changes is happening in the same day. But if the time changes happens across the day following is the behavior.

for e.g. consider

CASE1: On 04 April 2004, suppose Time Changes from 22:59:59 -> 00:00 (Time changes from EST to EDT)

The resetting of DIRP Sequence number will happen when the new billing file opens on April 05 2004 after 00:00 hr.

CASE 2: On 31 October 2004, suppose Time Changes from 00:29:59 -> 23:30 (Time changes from EDT to EST)

In this case, resetting of DIRP sequence number will not happen again when the time changes from Oct 30 midnight(23:59 EST) to (00:00)Oct 31 , since the previously set date in Mib was of October 31.

i.e. The reset of DIRP Sequence number will occur only if current Date is greater than the date which was set in the Mib.

9.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies are introduced by this feature

9.4 Software Requirements or Dependencies

None

9.5 Limitations and restrictions

- The option of 'Files closed at scheduled intervals from midnight' is mutually exclusive to the existing option of 'Files Closed based on a time limit'
- The Option of 'Reset DIRP Sequence Number at Midnight' is mutually exclusive to the existing option of 'Files renamed with close date'.
- This feature supports only Scheduled Rotation as '24 Hours','12 Hours','6 Hours','2 Hours','1 Hour','30 Minutes','15 Minutes', '10 Minutes' and'5 Minutes'
- If there are large numbers of billing files, then the file closure may get delayed since the OS not Real time
- File Closure may get delayed when SBAStreams is busy writing the billing records to the disk

- Billing File name does not guarantee that all the records are in line with the file closure time, in the event of any delay in transferring the call records from core to SBA
- During the event of BSY of SBA, prior to the scheduled closure of billing files all the open files will get closed.
- During Daylight Saving Time, the file closure does not happen at the exact schedule time.
- If the functionality is enabled by using Change command from CONFSTRM then the functionality will be activated only for the newly opened Files

10: Functional Description (FN) A00008323

10.1 Feature name and Feature ID

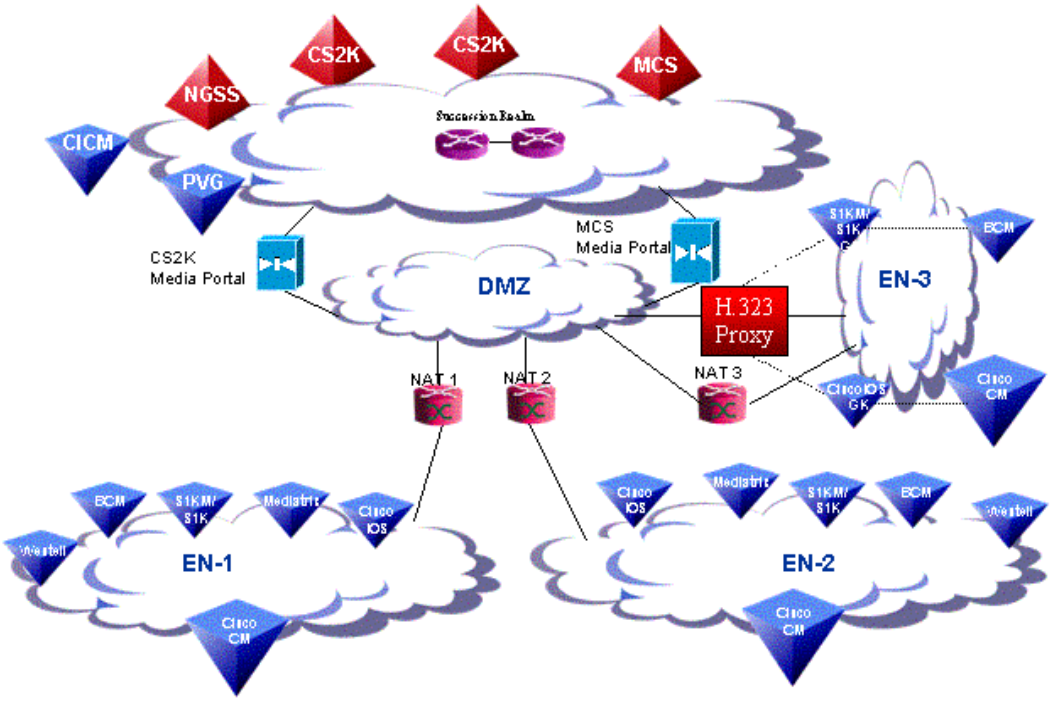
A00008323 H.323 64k UDI

10.2 Description

Besides packetization and depacketization, a VoIP media gateway performs additional processing on the media stream which it sends and receives. For example, the VoIP gateway may perform echo cancellation, DTMF detection, and encoding/decoding on the media stream.

However, there is a class of data streams that does not allow any data processing within the VoIP media gateway except for packetization and depacketization. ISDN data terminals, for example, will produce data streams that are not compatible with a non-linear encoding that is used for voice. For such applications, there exists a necessity for a bit-transparent relay of 64 kbit/s data streams in Real-time Transport Protocol (RTP) packets. This mode is often referred to as *Clear Channel Data* (CCD) or *64 kbit/s unrestricted data.*[1] No encoder or decoder is needed for CCD. However, a unique RTP payload type is necessary, and a related MIME type is to be registered for signaling purposes.

[1]CCD mode is not restricted to ISDN. It can be used by any application that does not need special encoding/decoding for transfer via an RTP connection.



CCD Mode in Succession CS2K

Existing VoIP vocoders (e.g. G.711, G.729) are not suitable to transmit a bit-transparent 64 kbit/s data stream. When processing a 64 kbit/s data stream, gateways should behave as follows:

- Gateways must turn off all voice processing features such as echo cancellation, DTMF detection, silence suppression, comfort noise insertion, A-law/u-law conversion, gain adjustment and packet loss concealment.
- Gateways should increase their jitter buffer size by 2 to reduce the possibility of buffer under-runs.
- Transport of the CCD stream through the gateway must be bit exact.

The H.323 standards (H.323, H.225 or H.245, H.323 implementation guide) do not provide stipulations for clear channel data within H.245 messages (for example in TCS, OLC). While the use of a bit-transparent 64 kbit/s channel can be signaled in the Bearer Capability information element of the H.225 SETUP message, it is not possible to advertise or negotiate the CCD capability in H.245 messaging. There is no standard codec defined in the industry to describe CCD data streams, so dynamic payload types must be used. In order to convey dynamic payload types in H.245, non-standard identifiers must be defined and agreed upon. Any solution based on this approach is therefore by default proprietary.

The Succession CS2K uses dynamic payload type 101, as specified in the SN07 IP Gateway InterOP Requirements, to indicate 64 kbit/s unrestricted data. The outgoing SDP for 64 kbit/s unrestricted data includes dynamic payload type 101 and rtpmap:101 X-CCD / clock-rate.

A sample outgoing SDP is illustrated below.

Figure 1 Example SDP: Gateway is requested to use 64 kbit/s unrestricted data

```
v=0
o=H323 0 0 IN IP4 172.29.224.26
c=IN IP4 172.29.224.26
m=audio 16398 RTP/AVP 101
a=rtpmap:101 X-CCD/8000
a=ptime:20
```

Succession CS2K CCD Interworking Requirements for H.323 Gateways

If the use of a bit-transparent 64 kbit/s channel is signaled in the Bearer Capability information element of the H.225 SETUP message (BC = UDI), the H.323 gateway should behave as follows.

Calls from H.323 gateway to CS2K:

- The H.323 gateway autonomously transitions to CCD mode.
- No requestMode commands are sent by the gatekeeper or by the H.323 gateway.
- Gateways shall use either 10ms or 20 ms packetization rate and signal this in the TCS.
- A non-standard CCD codec is not introduced. H.323 gateways may still use G.711 as codec in the TCS/OLC/Fast start element exchange, but the CS2K will ignore this information in case of UDI request in H.225 signaling.

- H.323 gateways must use dynamic payload type 101 for all CCD media streams.
- CCD calls cannot be converted to voice calls, and vice-versa.

Calls from CS2K to H.323 gateway:

- Upon receiving a H.225 SETUP with BC = UDI, the H.323 gateway must autonomously transition to CCD mode.
- No requestMode commands are sent by the GWC or by the H.323 gateway.
- CS2K shall signal the packetization rate from the far end in the TCS/OLC/Fast start element exchange (10 or 20 ms).
- H.323 gateway must expect and be able to handle dynamic payload type 101 for CCD media streams.
- CS2K signals G.711 as codec in the TCS/OLC/Fast start element exchange but the H.323 gateway must ignore this information in case of UDI request in H.225 signaling.
- CCD calls cannot be converted to voice calls, and vice-versa.

Note: There is no change to the gatekeeper functionality when interworking to non-H323 gateways that support CCD. The Session Descriptor is unchanged in this case as per the SN07 Succession Gateway Interoperability Requirements.

10.3 Hardware Requirements or Dependencies

There no CS2K hardware dependency, however needs customer provides devices to enable 64K UDI data transporting capabilities.

10.4 Software Requirements or Dependencies

This feature is sourced in SN09 and patched back to SN07 and SN08.

This feature requires H.323 Bearer Capability transparency which was sourced in SN07.

10.5 Limitations and restrictions

Not applicable.

10.6 Interactions

Not applicable.

11: Functional Description (FN) A00008522

11.1 Feature name and Feature ID

A00008522, SESM Support for SIP Lines

11.2 Description

Feature A00008522 will deliver the lines flow through and pre-provisioning functionality in the Succession Element and Sub-element Manager (SESM) required for the Session Server (SS) integration with Succession. The design will be split into Nodes provisioning for SS virtual gateways (GWs), and lines provisioning for SIP terminations/users.

The Nodes provisioning feature component will provide for the provisioning of SS GWs. Nodes provisioning will also provide functionality to pre-provision the SIP terminations in the GWC-EM and to pre-provision LENs (Line Equipment Numbers) in XACore table LNINV. The Lines Provisioning component will provide flow through of service information entered at OSSGate (SERVORD+ commands). New line provisioning functionality will be delivered to allow line data to be transmitted to the SS Element Manager (SS-EM).

11.2.1 SS Provision Concepts

From figure 1, the interaction of various devices and tables is shown. Starting with the upper left is Table SITE in the CM. These site names are used to name line groups in the CS2KSS. This is performed during provisioning the GW.

From the example, GWC 0 has two GWs provisioned (also called a virtual gateway or VMG) called GW0_SM1 and GW1_SM2. More than GW is permitted on a GWC, as long as the GWs refer to different SS gateways. The GWC may support up to 12276 lines, or 12 LGRPs (12 LGRPs * 1023 endpoints per LGRP). These 12 LGRPs may be distributed over the 2 provisioned GWs in any fashion.

Note that multiple site names can be used in naming the LGRPs and the site names can span multiple GWs. The frame and group portions of the LGRP name are determined by the SESM/Nodes Provisioning and not by the user.

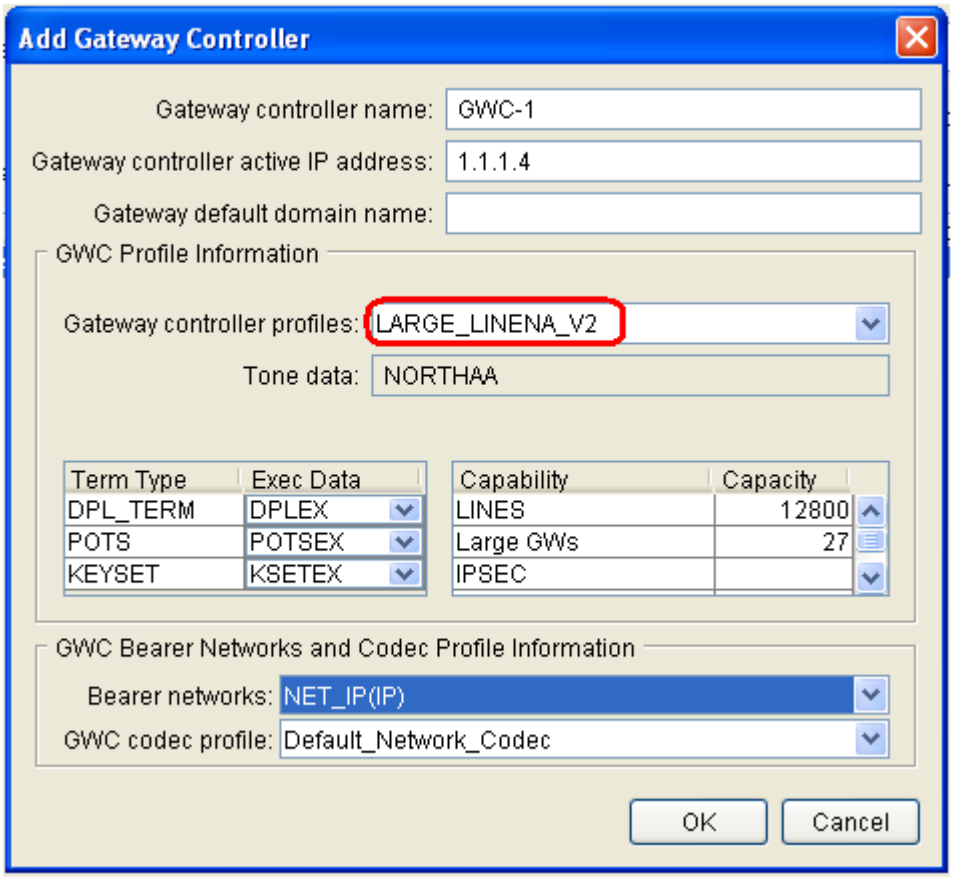
11.2.2 Adding a GWC

11.2.2.1 Add GWC

GWCs for CS2K Session Server gateways are provisioned using either the Large_LineNA_v2 or Large_LineINTL_v2 GWC profile. These GWC profiles will cause a GWC to be added to the CM, table SERVRINV, with the exec lineup of DPLEX/DPL, POTSEX/POT and KSETEX/KEYSET.

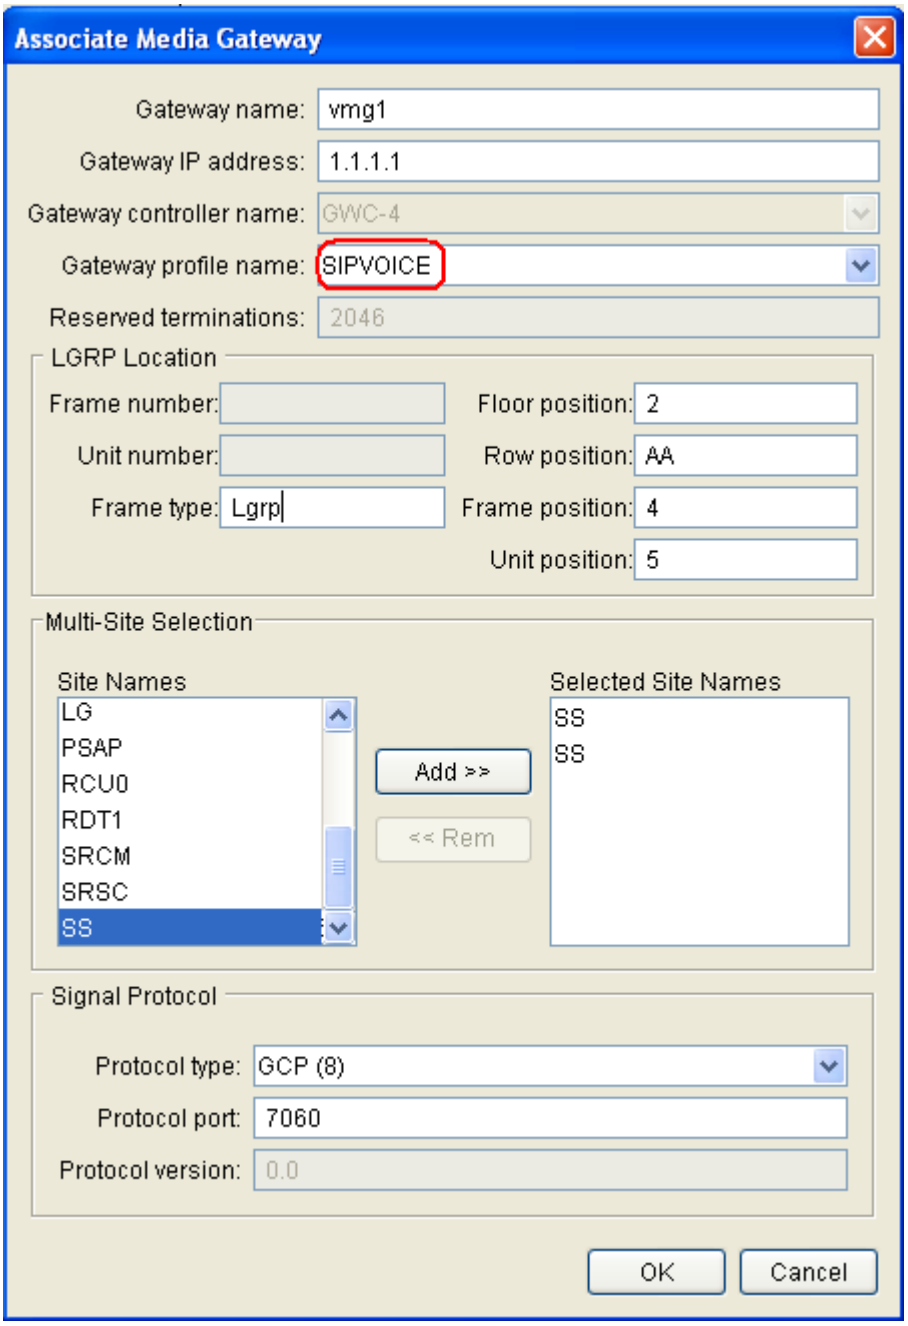


Also, the addition of these GWC profiles will update the GWC with a DPL enabled in the GWC configuration/capacity (GWC-PROFILE-MIB change).

11.2.2.2 Delete GWC

There are no changes required for this action.

11.2.2.3 Add GW



Adding a GW involves identifying a gateway name, IP address and selecting the SIPVOICE profile from the Gateway profile name list. The SIPVOICE selection causes an LGRP Location and Multi-Site Selection panel to appear.

The LGRP Location panel is used to provide the physical equipment location of the GW. LGRP_type is a string. Floor position, frame position and unit positions are all integers while row position is a char ‘A’ - ‘Z’, ‘AA’ or ‘AB’.

Below the LGRP Location panel is the Multi-Site Selection panel. Within this panel is a Site Names list and a Selected Site Names list. The Site Names list consists of all of the site names from table SITE in the CM. Site names are selected (placed in the Selected Site Name list) by simply clicking on the site name and selecting Add.

For SN09, a maximum of 12 site names can be selected. The same site name may be used multiple times by selecting Add several times.

Each site name represents one LGRP as defined by:

<site>/frame/group

Each LGRP is provisioned in table LGRPINV (CM) and represents 1023 endpoints. Each endpoint is added to table LNINV as:

<site> frame group terminal

where the terminal number ranges from 00 00 to 10 22.

The reserved termination field is updated as the Add button is selected.

The entries in the Signal Protocol panel are defaulted but can be changed.

Note: **Adding a fully provisioned CS2K SS GW will require approximately 10 minutes, or 2 minutes per LGRP.**

Note: Provisioning SIP GWs can only be performed one at a time. Attempts to provision multiple SIP GWs at the same time may cause all provisioning sessions to fail.

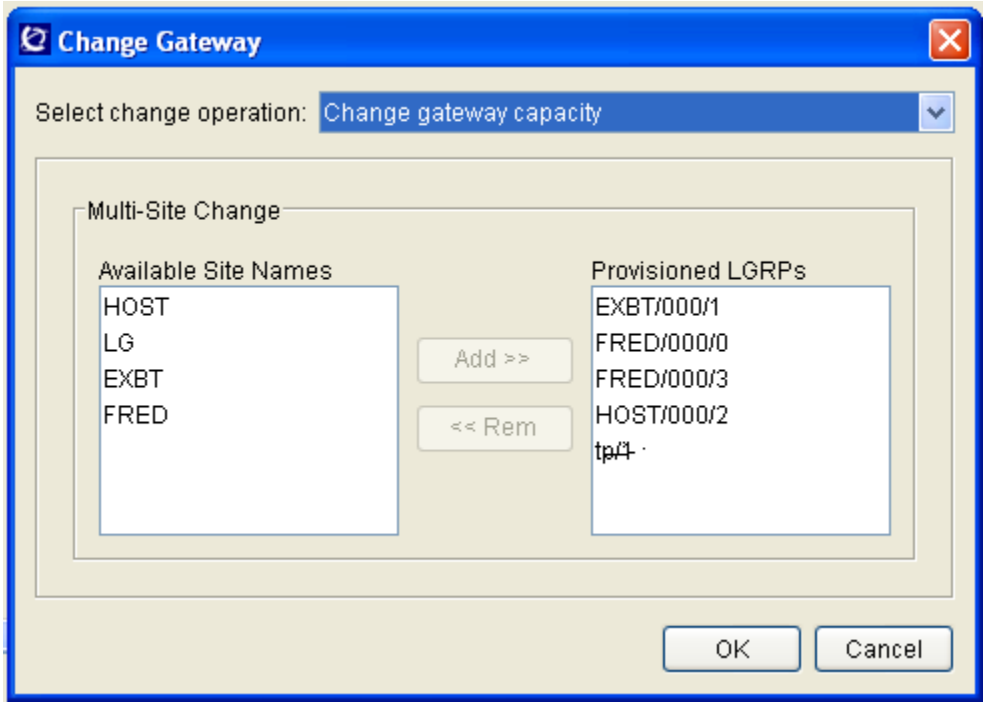
11.2.3 Design Solution / Module Flow Diagram

Addition of a GW includes (in order)

1. adding the GW to the GWC
2. adding one LGRP to LGRPINV (CM)
3. adding the associated endpoint groups (TN’s) for that LGRP to the GWC
4. adding the LENs to LNINV
5. Repeat steps 2-4 until all LGRPs have been added

11.2.3.1 Change GW

Figure 2 Change Gateway Capacity - Multi Site Dialog box



A gateway using the SIPVOICE profile will have the dialog box in figure 2 displayed. Similar to the AssocGW dialog box, this box contains two lists, Available Site Names on the left, which is a list of site names from the table SITE in the CM.

The second list, “Provisioned LGRPs”, is a list of site names already used and assigned. These site names have LGRPs and LENs assigned to it, therefore they show up with there respective frame and group numbers.

From this dialog box, the user can add additional site names (a maximum of 12 LGRP/Site names) are permitted in the Provisioned LGRPs list.

Additionally, the user can select to remove LGRP/Site names from the provisioned list simply by selecting them and the remove button.

Once the site names have been added, and OK selected, this diialog box will close and another panel will appear to display the progress and responses. The first item to display is the timeout value.

Cancel will close the box without executing any operation.

Note: Only single operations may be performed from the Change Gateway dialog; in other words, the user cannot add one site and remove another site in the same operation.

11.2.4 Configure

In the SESM, the /opt/nortel/NTsesm/admin/bin/configure tool should be used to configure SESM access to the Session Server Element Manager (SS-EM).

The configuration tool will prompt the user to enter the following:

- Transport protocol to SS-EM server (http/https - default is https). In SN09, only HTTPS is supported by the SS-EM, however flexibilty to choose HTTP is still provided to meet possible future needs.
- IP address / host name of primary SS-EM server
- IP address / host name of secondary SS-EM server. Some configurations may not include a secondary SS EM server. If so, configure the same information provided for the primary server (by default this should be the case).
- HTTP/HTTPS communication port to SS EM server (default 8080 for http, 8443 for https).
- The OPIClient version. This is mapped to the SS EM load version. In SN09, the appropriate value will be “9.0”. The OPIClient version should be incremented each release in steps of 1.0 i.e, 9.0, 10.0...15.0
- SS-EM Provisioning Manager administrator user name
- SS-EM Provisioning Manager administrator password

The IP address and port will be used to generate the SS-EM Provisioning Manager URL which in turn will be added to sesm.properties file.

As part of the configuration, the IP address will be validated for format, range and reachability. Other user entered data will be validated for format, range, values etc.

The user name will be added to sesm.properties as clear text.

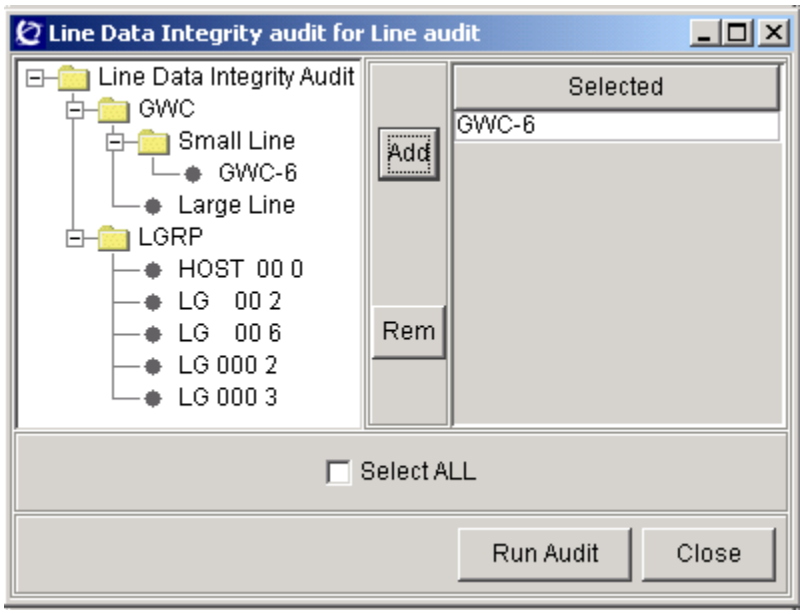
The password will be stored separately and accessible only to the root user.

All configuration information (url, username, etc.) except password can be displayed by using the SESM “/opt/nortel/NTsesm/admin/bin/configure” tool.

11.2.5 Audits

- Add a new gui to provide support for audit by GWCs, GWs or LGRPs. Only support Line Data Integrity audit now.

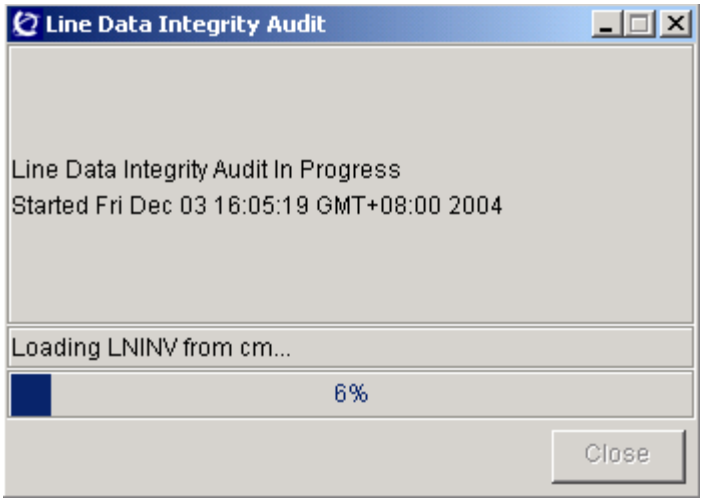
When users select “Line Data Integrity Audit” and press the “Run Audit” button in Audit System gui, the following gui will be displayed.



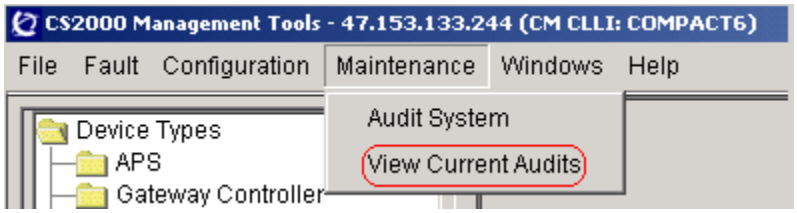
- User can select the gwc, gw or lgrp in the left tree and add them to the selected table by press the “Add” button.
- User can select the gwc, gw or lgrp in the right table and delete them from the table by press the “Rem” button.
- User can select all datas to do audit by select checkbox “Select All”. When user select the datas to do audit, the “Run Audit” button will be highlight.
- After user selected the data and press “Run Audit” button, the audit will be run as before.

- Add a progress bar in “Run Audit” gui to indicate the progress of the running audit.

Add a label to show current operation.

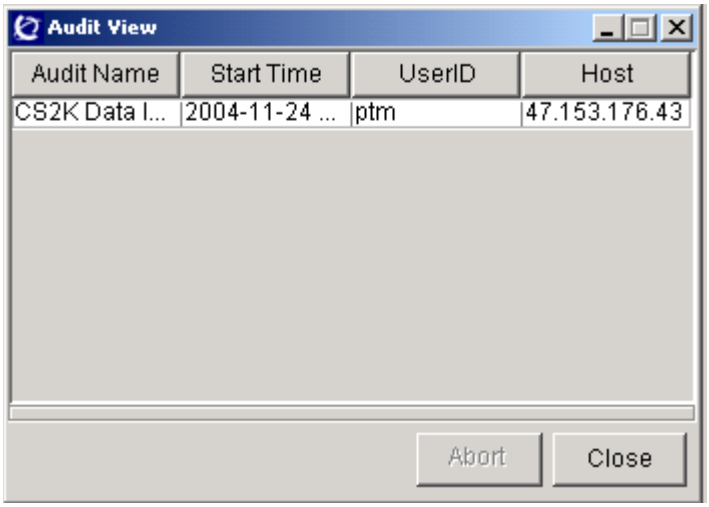


- Add a new menu in Maintenance of Cs2kmt to provide the new function “Abort Audit”.



When user selected the menu “View Current Audits”, another new gui will be displayed.

- Add a new gui to provide the new function “Abort Audit”.



The running audits will be displayed in this gui. The data of the audits include: Audit Name, Start Time, UserID, Host.

User can selected a running Audit and press the “Abort” button to abort the audit.

11.3 Hardware Requirements or Dependencies

Not applicable.

11.4 Software Requirements or Dependencies

This actrivity requires that the following components are loaded with SN09 or equalivalent loads.

CM, XAC or 3PC

GWC

MSM

11.5 Limitations and restrictions

None.

11.6 Interactions

This feature will integrate the SIP client provisioning with the existing Succession SERVORD+ system. SIP client commands/data are distributed to the SS-EM from the SERVORD+ system within the SESM. The following commands will trigger data distribution to the SS-EM from SESM SERVORD+ when SS vmgs/endpoints are found within the command: NEW, OUT, CHF

NOTE: CHF requires the use of gateway/termination names (or the equivalent LEN) in order to trigger flow through for SS lines. Use of DN will result in the command being processed only by the CM.

Query commands QLEN/QTP and QDN (which return formatted line/service information) will include the SIP_DATA options provisioned via the NEW/CHF commands in their output. The SIP_DATA option information will be appended to the end of the existing QLEN/QDN output, but prior to the dashed line (eg. “----------”) query output terminator line.

New data tags presented in query output with sample values:

END POINT DATA: *(This is the endpoint data header, no info/value associated with this tag)*

11.7 Glossary

Term	Description
New term	Definition

12: Functional Description (FN) A00008601

12.1 Feature name and Feature ID

ACT: A00008601, IW-SPM-IP Fully Provisionable Codec Lists for G.711/ G.729.

12.2 Description

This feature is to allow IW SPM IP's Codec list to be fully provisionable for G.711 and G.729.

The existing functionality of IW-SPM-IP supports the following two codec configurations.

1. G.711 Only

2. G.729 Preferred (1st Choice) and G.711 Supported(2nd Choice).

This feature extends the codec support of IW SPM IP by allowing codec list to be fully provisionable for G.711 and G.729. With this feature the following codec configuration can be provisionable in MNIPPARM table:

a. G.711 Only (G711 as default codec and NONE as preferred codec)

b. G.729 (preferred) / G.711(2nd Choice)

c. G.711 (preferred) / G.729(2nd Choice)

d. G729 Only (G729 as default codec and NONE as preferred codec).

The following codec list can be supported by IWIP SPM from SN09 for codec negotiation with the far end:

Table 1: Codec list supported by IWIP SPM from SN09

PRFCODEC **in MNIPPARM table**	**DFCODEC in MNIPPARM table**	Codec list supported by IWIP SPM
None	G711ALAW	G711ALAW, G711MuLAW
None	G711MuLAW	G711MuLAW, G711ALAW
None	G729	G729
G711ALAW	G729	G711ALAW, G711MuLAW, G729
G711MuLAW	G729	G711MuLAW,G711ALAW, G729
G729	G711ALAW	G729, G711ALAW, G711MuLAW

PRFCODEC **in MNIPPARM table**	**DFCODEC in MNIPPARM table**	Codec list supported by IWIP SPM
G729	G711MuLAW	G729, G711MuLAW, G711ALAW

Definitions for G711 and G729 codec are as follows:

G.711 is 64kbps codec. When G.711 is used, overall voice quality provided by IW-IP will have an ITU R Rating (G.107) of 90, which corresponds to a minimum average MOS of 4.3 (“Very Satisfactory” speech quality).

G.729 is 8kbps codec. When G.729A is used, overall voice quality provided by IW-IP will have an ITU R Rating (G.107) of 80, which corresponds to a minimum average MOS of 4.0 (“Satisfactory” speech quality).

Codec information is already provisionable in default codec[DFCODEC] and preferred codec[PRFCODEC] fields of MNIPPARM table. This feature only adds new values to support full provisioning of codec.

The default values of these fields remains same. The default value for DFCODEC filed is G711ULAW and the default value for PRFCODEC field is NONE.

Detailed information is available in Configuration Section.

12.3 Hardware Requirements or Dependencies

No new hardware required for this feature

12.4 Software Requirements or Dependencies

This functionality requires SN09 load in the Call Server, IW-IP CEM and GEM RM.

12.5 Limitations and restrictions

None

12.6 Interactions

None

12.7 Glossary

Term	**Description**

IW	Inter Working
MOS	Mean Opinion Score
RM	Resource Module
SPM	Spectrum Peripheral Module
TDM	Time Division Multiplexer

13: Functional Description (FN) A00008629

13.1 Feature name

GEM-II AAL2 IW-SPM SN09 Core Preparation Work

Notice a change in nomenclature. When referencing the original GEM card or GEM RM, GEM means “GigE Module” for IP applications. But when referencing the new GEM-II card, GEM means “Generic Equipment Module” since GEM-II can support either Gig-E (IP) and AAL2 applications.

13.2 Description

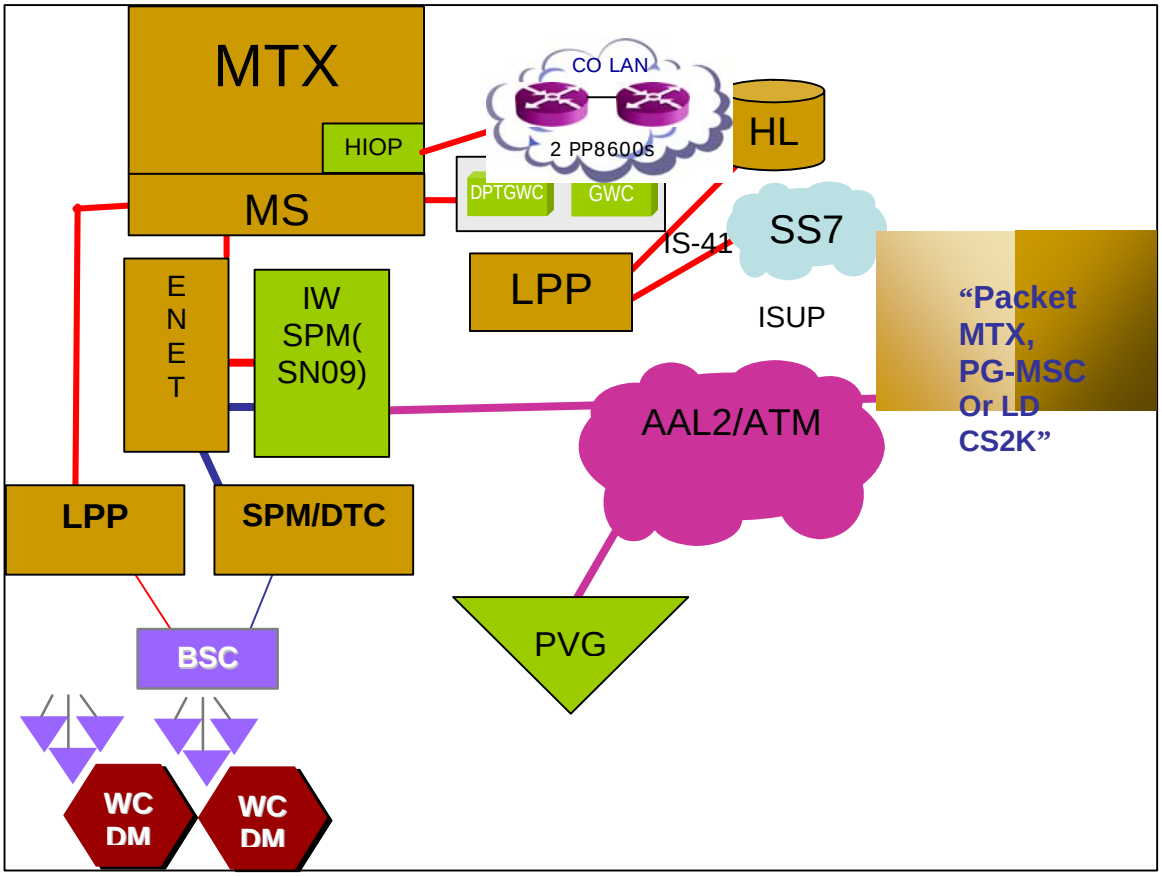
This activity implements all Core work in SN09 for the AAL2 ATM feature being delivered in MTX14. The AAL2 IW-SPM feature will allow customers of CDMA Wireless MTX switches to extend their ENET connected peripherals to ATM networks for voice and data call processing over AAL2 connections.

The ATM/AAL2 RM, based on the new ‘Generic Equipment Module 2’ (GEM-II) NTLZ20DA circuit pack, will be delivered as part of the Succession IW-SPM product offering beginning in the MG4K23 release. The GEM-II hardware is being introduced in SN09/MG4K22 as a replacement for the ‘Giga-bit Ethernet Module’ (GEM) RM which supports IP applications. The GEM-II RM has additional hardware capability of supporting ATM based applications over AAL2. The GEM-II runs on an IW-SPM configured as IP or AAL2. The GEM II provides PQII, TI DSPs (on board), winpath787, ECAN tone detection, generation, vocoding, etc.

Working AAL2 functionality will be delivered in MTX14, which is based on SN09 and MG4K23. The required AAL2 local code in the CEM and RM will be delivered in MG4K23. The A00008629 Core activity is being done in SN09 as a preparation activity to avoid later patching of the Core. With activity A00008629, the customer can datafill an IW-SPM as AAL2 bearer fabric with NTLZ20DA as an ATM RM. The customer can also datafill the AAL2 protocol parameters and the five required ATM carriers (same 5 that are required on AAL1 ATMs). A single office parm will control whether the AAL2 IW-SPM feature is active; this parm is “off” by default and should be enabled in MTX14 once the production MG4K23 loads become available.

Figure 1 below shows a network diagram of a wireless MTX switch with the AAL2 IW-SPM bridging calls from SPM/DTC over AAL2 to PVG.

Figure 1 Wireless Base Station Network using IW-SPM AAL2 solution. Note



that there is also a TDM bearer path connection between BSC and PVG.

13.3 Hardware Requirements or Dependencies

The new NTLZ20DA GEM-II circuit pack is being introduced in SN09 for IP applications running on a GEM-type RM. In MTX14, this same NTLZ20DA pack can be configured in software to work as an ATM RM providing AAL2 connectivity.

The GEM-II pack provides these external user interfaces on the faceplate, listed in top-down order:

1. Red triangular LED: works like standard SPM RM to indicate OOS status. When lit, card is OOS; when blank, card is InSv.
2. Green square LED: works like standard SPM RM to indicate activity status. When lit, card is active; when blank, card is in standby mode.
3. Green circular LED labeled "LINK": lights steady to indicate signal is being received; blank if no signal is being received. For AAL2 application, this signal would be the SONET signal from the far end. For IP application, this signal would be the Ethernet signal from the CS2K.

4. SFP (Small Form Pluggable) connector: for IP applications, this connector accepts a MT-RJ or LC plug that provides GigE (Gigabit Ethernet) interface for 1000B-SX or 1000B-LX. For AAL2 applications, this connector accepts a LC plug that provides OC3 SONET interface for SR (Short Reach), IM (Intermediate Reach), or LR (Long Reach). The SFP connector is compliant with specification SFF-8472 revision 9.3 (produced by the SFF Committee).

For AAL2, the transmit and receive SONET fibers are connected to an OC3 SONET plug inserted in the SFP. Note that the SFP interface is considered part of the cable and hence will not be ordered with the card.

The supported cable types for both SONET and GigE applications are:

a. single mode: good up to 5-6km and always uses a laser.

b. multi mode: good up 500m and can use LED instead of laser.

13.4 Software Requirements or Dependencies

A new GM2xxxx firmware load will be introduced in SN09/MG4K22 for the GEM-II configured as GEM RM for IP application.

In MG4K23, a new AL2xxxx load will be introduced to provide the AAL2 application on the GEM-II card. This new AL2xxxx load will only be supported on a GEM-II card configured as an ATM RM on a IW-SPM configured for AAL2 ATM fabric.

CEM changes are also required in MG4K23 for the IWSxxxx load to support AAL2 on the IW-SPM.

13.5 Limitations and restrictions

1. Attempts to load or RTS AAL2 ATM RM in SN09 are not permitted until the MG4K23 loads are available for the CEM and RM. Hence, AAL2 calls cannot be made until MTX14 when MG4K23 loads are available.
2. The GEM-II card can operate as IP or AAL2, but not both at the same time.

13.6 Interactions

Feature A00007926 was implemented in SN08 to introduce provisioning of the new NTLZ20DA PEC code for IP applications. In SN09, this same NTLZ20DA PEC code can be datafilled for AAL2 applications.

14: Functional Description (FN): A00008724

14.1 Feature name and Feature ID

A00008724: OMDD Enhancements and Robustness.

14.2 Description

This Activity address the following items:

1. Implementing a FTP retry mechanism for OMDD application: If FTP fails to send OM reports to any of the configured downstream machines for various reasons like downstream reboot, network congestion, password change and maintenance in downstream etc., those reports will be attempted to be sent to downstream at the next scheduled interval.
2. Improving OMDD audit mechanism: With current design there is a possibility of omdata filesystem getting filled up before the audit happens. Current audit period is every 6 hours. The improved audit mechanism will ensure that the omdata filesystem will not reach 100% at any instance for the currently supported OM capacity for SN09 release.
3. Enhancing file rotation mechanism: Currently there is a file rotation problem from *open* to *closedNotSent* directory when SDM/CBM and CM are not in sync with respect to time.This will result in configured downstream not receiving OM reports at scheduled time. This activity will make sure that all OM reports will be sent to downstream according to configured schedule.

14.3 Introducing ftp retry mechanism

Currently user can configure OMDD to send OM report to single/multiple downstream destinations. If the ftp fails for some reason, OMDD will not try to send the OM reports downstream again and the files are moved from *closedNotSent* to *closedSent* directory. To be specific, once ftp is attempted for an OM report file, OMDD will move the file to *closedSent* directory irrespective of the success or failure of the file transfer. On failure cases, log will be generated to notify the failure of the file transfer.

In case of failure to transfer the OM reports to downstream destination, this activity will ensure that reports are re-attempted to be sent.

If the OM report transfer fails for any destination, OMDD will keep track of the destination to which the report could not be transferred. At the next File Transfer Schedule, OMDD will attempt to send the report to the destination again. This will be done on every file transfer schedule until

- a successful transfer or
- this file exceeds the retention period of the *closedNotSent* directory or
- the file gets deleted during audit.

14.4 Improving OMDD Audit mechanism

OM reports are stored in omdata filesystem. Currently, this filesystem is audited every 6 hours. During the audit, if omdata filesystem usage is found to be more than 60%, then OMDD generates a warning log to the user stating *"ODM: WARNING omdata storage use exceeds 60 percent. Files will be deleted in next audit if the usage exceeds 70 percent"*.
In the next audit, if omdata filesystem usage is found to be more than 70%, then OMDD deletes all the files from *closedSent* directory. The filesystem usage will be calculated again and if is still more than 50%, files from *closedNotSent* directory will be deleted starting from the oldest file.This procedure is repeated till omdata filesystem usage is less than or equal to 50%. Customer will be notified on deletion of each file from *closedNotSent* directory through *Major* log.

With the current audit interval of 6 hours, there is still a high chance that omdata filesystem might get filled up in between two audits.

This activity will reduce the audit interval to 30 minutes with the following changes:

- Generate Major log when omdata filesystem usage reaches 60%.
- Generate Major Trouble log when omdata filesystem usage reaches 80%.
- Generate Info log and delete all files in *closedSent* directory on reaching 90% usage of omdata filesystem.
- If omdata filesystem usage does not fall below 80% after deletion of all the files in *closedSent* directory, files from *closedNotSent* directory will be deleted starting from the oldest file till the usage reaches 80% or less.
- Generate Info log for each file deletion from *closedNotSent* directory.
- Generate the corresponding Clear logs for all Major logs.

This activity will ensure that omdata filesystem usage will not reach 100% at any instance for the currently supported OM capacity for SN09 release.

1. The following log is generated when audit finds omdata filesystem usage exceeds 60%.
SDM338 MAJOR TBL SDM OM FILE RETENTION
ODM: Audit finds omdata usage exceeds 60 percent.OM files will be deleted in the next audit if the usage exceeds 90 percent.

2. The following clear log is generated when audit finds omdata filesystem usage goes below 60%.
SDM638 NONE INFO SDM OM FILE RETENTION
ODM: Audit finds omdata usage has gone below 60 percent.

3. The following log is generated when audit finds omdata filesystem usage exceeds 80%
SDM338 MAJOR TBL SDM OM FILE RETENTION
ODM: Audit finds omdata usage exceeds 80 percent.OM files will be deleted in the next audit if the usage exceeds 90 percent.

4. The following clear log is generated when audit finds omdata filesystem usage goes below 80%
SDM638 NONE INFO SDM OM FILE RETENTION
ODM: Audit finds omdata usage has gone below 80 percent.

5. The following log that is generated when audit finds omdata filesystem usage exceeds 90%
SDM639 NONE INFO SDM OM FILE RETENTION
ODM: Audit finds omdata usage exceeds 90 percent.All the OM files from closedSent directory will be deleted now

6. The following log is generated when a file in *closedNotSent* directory is deleted by audit to make morethan 80% available space in omdata filesystem.
SDM631 MINOR INFO SDM OM FILE RETENTION
ODM:The File<filename> from closedNotSent directory deleted by audit to free up space in omdata.

-where <filename> is the name of the file deleted from *closedNotSent* directory.

14.5 Enhancing File Rotation Timer

OM reports for an office transfer(OT) period will be sent from CM in either 15 or 30 minutes interval based on the CM configuration.When SDM and CM are out of sync by ~3 minutes OMDD fails to trigger the file rotation from *open* to *closedNotSent* directory in accordance with file rotation schedule[FRS]. This causes reports not reaching the downstream on time.

This activity will enhance the file rotation mechanism, so that files are rotated in accordance with FRS even when SDM/CBM and CM are not in sync.

14.6 Hardware Requirements or Dependencies

- SDM with basic configuration
- CBM with basic configuration

14.7 Software Requirements or Dependencies

Latest SDM22/CBM22 load with Table Access and OM Access services should be in service.

CM - SDM/CBM connectivity should be up.

Term	Description
LCI	Local Craft Interface – A web based user interface
FITS	Fault Insertion TestS

16: Functional Description (FN): A00008858

16.1 Feature name and Feature ID

Feature A00008858: CS2M and MG9KEM User Inactivity Time-out

16.2 Description

This SN09 feature provides a standard and consistent design across MG9KEM and CallServer 2000 Management Tools (CMT) for client user inactivity time-out. There are three timers that will be configurable from the SSPFS CLI after the initial SSPFS installation. The three timers are:

- User Inactivity Timeout
- User Termination Timeout
- Reauthentication Disable Timeout

16.2.1 Configuration Behavior

Default Assignment - The default value of 10 minutes will be set on SSPFS installation for User Inactivity Timeout and User Termination Timeou. The default for Reauthentication Disable Timeout will be 30 seconds.

Accepted Values - The values for User Inactivity Timeout and User Termination Timeout can be entered in increments of full minutes(e.g 1, 2,3) The values can range from a minimum of 5 minute to a maximum of 1440 minutes(24 hours). The value ‘0’ will be used to indicate that no timeout implementation is desired, effectively turning this feature off.This applies to either value as follows. The accepted values for Reauthentication Disable Timeout are 0-300 in seconds.

- If the user wants to turn off the entire timeout feature, a value of ‘0’ for USER_INACTIVITY_TIMEOUT will indicate this.
- If the user wants the timeout feature to be activated but does not desire a USER_TERMINATION_TIMEOUT to be enforced, the value ‘0’ will indicate this

When the CLI is used to configure the timeout values, they will take effect immediately for all new client launches. No restart is required. The configuration access is located centrally to all supported applications and requires ‘root’ access to the SSPFS server.

16.2.2 CLUI Behavior

After user runs the CLUI, If there is no user input on the command line for the duration of the first timer, the process is killed and user exits from the session to the shell.

16.2.3 General GUI Behavior

When the User Inactivity Timeout expires for a given application, all application windows will be minimized, which prevents all users input and provides no data output to the user. Proper login authentication is required to release the application lock and make the application visible. Once the re-authentication occurs, the user's desktop view will be restored with no updates lost.If the application user does not re-authenticate within an acceptable time frame, as defined by the User Termination Timeout, the application user will be forced to exit the application before making another authentication request. Note that the User Termination Timeout does not start until the User Inactivity Timeout expires.

16.2.4 Re-authentication Behavior

The SSPFS Security Servlet enforces security limitations during re-authentication attempts. No userid will be displayed in the re-authentication window. If there are 3 failed authentication attempts, the re-authentication window will be locked for 30 seconds. After the 30 second timer, which is configurable, re-authentication will be allowed.

Table 1 Application Behavior Summary

Type	Name	Behavior
Launch Page	CS2M Launch Point	After user launches the Launch Page, If there are no user initiated mouse movements for the duration of the first timer, the client is iconizied and a dialog is popped up to prompt the user re-login. Only after successful re-authentication, the launch page is de-iconized. If there are no user initiated mouse movements on the screen for the duration of the second timer (At that time the client should be iconized and a login dialog is shown), a warning dialog is popped up which saying that the client is locked due to long time non-operation. When user confirm it, the client as well as the re-login dialog are both closed.

If there is no user input on the command line for the duration of the shell time out value, user will exist from the shell automatically.

16.3 Hardware Requirements or Dependencies

None.

16.4 Software Requirements or Dependencies

None

16.5 Limitations and restrictions

Limitations and restrictions are:

1) The following CLUIs which run inside SSH/Telnet session, are not supported by this design. They are the SSPFS cli tool, SESM configure tool, App Start/Stop script and the Unix self-contained commands.

2) The UAS GUI is non-compliant with this design. There is no plan to support user inactivity timeout.

3) The APS GUI is partially compliant with this design. A fixed timeout is supported which logs the user out, but there is no re-login or minimization support planned

4) The Security Server Manager, used to configure secure IPSec connections between and SSPFS server and another destination(e.g. MG9000) is partially compliant to this design. A default 5 minute timeout exists and the user must initiate an action before being redirected to a page that will allow re-authentication. No changes were added to this functionality as a part of this feature.

5) There may be some platform specific behavor in the GUI desktop. This applies strictly to the requirement to restrict all user access and provide no data output to the user when the timeout occurs. Based on the software platform the top-level view may be iconified or disappear all together.

6) Although the configuration is centrally located within the SSPFS platform, the craftsperson or system administrator must manually ensure that the timeout values across SSPFS servers are kept in sync between CMT and MG9KEM servers if this is the desired behavior. In other words, as long as the defaults are in place the CMT and MG9KEM applications will behave in exactly the same manner. Once the administrator makes a change on one SSPFS server there is not a design or expectation that this will be automatically synchronized.

Note: Though no specific design support is planned for the Unix shell applications as mentioned herein, the SSPFS does currently support a shell timeout that will kill a shell session if there is no activity within a specific time period. The value for this shell timeout is configured via the /etc/profile file as the TMOUT value

17: Functional Description (FN): A00008916

17.1 Feature name and Feature ID

Feature A00008916: Gateway Controller Lines Density Increase

17.2 Description

With the introduction of the N905 Gateway Controller hardware there is now increased CPU speed and memory capacity. This enables increased port density and combined profiles. The new profiles introduced by this feature are only compatible with N905 GWC hardware and will not operate with MCP750 GWC hardware, therefore both GWC units MUST be loaded with N905 hardware before the GWC profile is migrated to one of the new N905 profiles.

The new profiles are forward compatible with certain existing profiles, allowing for in-service profile migrations. However, the new profiles are not backward compatible with previous profiles. In other words, once a N905 GWC is migrated to a new profile it cannot be migrated back to a previous profile. The only way to migrate backwards from high-density profile is to delete the GWC provisioning from the SESM database and re-provision the GWC.

17.2.1 Small Gateway Lines High Density Profiles

The High Density small line gateway profiles support 25,600 lines and small gateways without IPSEC turned on. If IPSEC is to be supported then the engineering limit is 12,800 gateways and lines. This is an engineering rule and is not enforced by the software, the software will allow up to 25,600 lines and gateways to be provisioned regardless of IPSEC. As noted above, once a GWC has been migrated to the high density profile it cannot be downward migrated to the previous profile without deleting the provisioning and re-provisioning with desired profile.

PROFILE NAME: SMALL_LINENA_V2

This profile is a high density version of the SMALL_LINENA profile. It enhances SMALL_LINENA by increasing line and gateway capacity from 6,400 to 25,600. This profile is compatible with SMALL_LINENA as part of an in-service upgrade.

TERM TYPE	EXEC DATA	TONEDATA
POTS	POTSEX	NORTHAA
KEYSET	KSETEX	

CAPABILITY	CAPACITY

KEYSET	KSETEX	

CAPABILITY	CAPACITY
Lines	25,600
Small Gateways	25,600
IPSEC	
Kerberos	
DQOS	80

17.2.2 Large Gateway Lines High Density Profiles

The High Density large line gateway profiles support 12,800 lines and small gateways with or without IPSEC. This profile also supports SIP Lines [DPL] (see feature A00008522 for details). As noted above, once a GWC has been migrated to the high density profile it cannot be downward migrated to the previous profile without deleting the provisioning and re-provisioning with desired profile.

PROFILE NAME: **LARGE_LINENA_V2**

This profile is a high density version of the LARGE_LINENA profile. It enhances LARGE_LINENA by increasing line capacity from 6,400 to 12,800 lines. This profile is compatible with LARGE_LINENA as part of an in-service upgrade.

TERM TYPE	EXEC DATA	TONEDATA

17.2.3 Combined Lines, Trunks, and Audio Profiles

These profiles combine the SMALL_LINE, LARGE_LINE, TRUNK, and AUDCNTL profiles into one combined profile at MCP750 capacities. This profile also supports SIP Lines [DPL] (see feature A00008522 for details). All gateway types and capabilities that are supported on the individual profiles are supported in this combined profile with the following exceptions:

- 250 PTS and PRI trunk types are not supported on the combined profile (250 ISUP trunks are supported). 250 PTS and PRI trunks must be removed before migrating to the combined profile.

As noted above, once a GWC has been migrated to this profile it cannot be downward migrated to the previous profile without deleting the provisioning and re-provisioning with desired profile.

PROFILE NAME: **LINE_TRUNK_AUD_NA**

This profile is a combination of the SMALL_LINENA, LARGE_LINENA and TRUNK_NA profiles. This profile is compatible with SMALL_LINENA, LARGE_LINENA, and TRUNK_NA as part of an in-service upgrade.

17.2.4 Profile Compatibility

The following table lists which new profiles are compatible with existing profiles. As noted above, once a GWC has been migrated to a N905 supported profile it cannot be downward migrated without deleting the provisioning and re-provisioning with desired profile.

Figure 1 Profile Compatibility Table

Existing Profile (SN08)	Compatible In-Service Upgrade To (SN09 Profile)
SMALL_LINENA	SMALL_LINENA_V2, LINE_TRUNK_AUD_NA
SMALL_LINEINTL	SMALL_LINEINTL_V2, LINE_TRUNK_AUD_INTL
LARGE_LINENA	LARGE_LINENA_V2, LINE_TRUNK_NA

LARGE_LINEINTL	LARGE_LINEINTL_V2, LINE_TRUNK_INTL
TRUNK_NA	LINE_TRUNK_AUD_NA
TRUNK_INTL	LINE_TRUNK_AUD_INTL
SIP_LINES_NA	LARGE_LINENA_V2, LINE_TRUNK_NA
SIP_LINES_INTL	LARGE_LINEINTL_V2, LINE_TRUNK_INTL

17.2.5 GWC Profile Migration Instructions

Once both GWC units have been upgrade to N905 hardware, the GWC profile can be migrated to one of the new N905 profiles using the SESM GUI. Following a successful GWC Profile change, both units of the Gateway Controller must be reloaded before the change takes affect, the GWC units are still running on previous profile until a lock/unlock is performed. An alarm is raised for each unit to indicate a data mismatch exists between the SESM server and the Gateway Controller. The alarm condition is displayed by the **Alarm Manager** accessed via the **Fault** menu. The alarm will be cleared once the GWC units have been reloaded.

1. Verify that both GWC units are N905 hardware.
2. Change Profile from SESM GUI (alarm will be generated).
3. (SESM GUI) **Busy** the inactive unit.
4. (SAM21 GUI) **Lock** and **Unlock** the associated card. The card is booted and provisioned data is downloaded following the unlock operation. The data mismatch alarm condition is cleared for this unit.
5. (SESM GUI) **RTS** the inactive unit.
6. (SESM GUI) **Warm Swact** the Gateway Controller.
7. Repeat steps 3 through 6 for the mate unit.

17.3 Hardware Requirements or Dependencies

This feature is dependent on the N905 GWC hardware.

17.4 Software Requirements or Dependencies

SN09 SESM, SAM-21 and GWC loads.

17.5 Limitations and restrictions

The new profiles are only supported on the N905 hardware. An MCP750 GWC will not come into service if it is provisioned with one of the new profiles. If the GWC card is pre-provisioned with a N905 profile and then loaded with MCP750 hardware and booted, an alarm will generated. This is

an unsupported configuration, both GWC units must be loaded with N905 hardware.

If an MCP750 profile is already in service (not a pre-provisioning case) the software will verify that N905 hardware exists before allowing the GWC profile change.

The new profiles are not backward compatible with any other profile. Therefore, the new N905 profile must be chosen carefully. Once the N905 GWC is in service on the new profile it cannot be changed without deleting provisioning on the GWC.

250 PTS and PRI trunk types are not supported on the combined profile (250 ISUP trunks are supported). 250 PTS and PRI trunks must be removed before migrating to the combined profile.

The N905 Small Gateway Lines profiles support 25,600 lines WITHOUT IPSEC. With IPSEC turned on 12,800 is the engineered limit. The limit is not enforced in provisioning however.

17.6 Interactions

None.

18: Functional Description (FN): A00008969

18.1 Feature name and Feature ID

Feature A00008969: ATM50 SSI Monitoring, Corrective

18.2 Description

This document defines and describes monitoring the rate of SSI(Signal State Change Interrupt) coming from the ATM ports and raising an alarm if the given threshold exceeded . This feature includes following parts:

- Collect the SSI event count from the all types of ATM ports.
- Decide that SSI alarm condition occurrence.
- Raise SSI alarm.

18.3 Problem Description

While investigating a recent ABI outage it was observed an exteremely high number of ATM50 SSI pegs occurred in the SCO & ITX cards. For this situation, monitor the rate of SSI (Signal State Change) indications from all types of ATM parts and alarm if the rate exceeds a given threshold. This feature will enable the detection of faulty hardware components in the field.

18.4 Adjustments made

Signal Condition Change Interrupts (SSI) are collected every minute for each port of the ATM50 device. Several variables are added to conduct counts and comparisons. If the SSI count is too high, an ATM50 SSI alarm is raised, called Hardware Port Unstable.

19: Functional Description (FN): A00009011

19.1 Feature name and Feature ID

Feature A00009011: Traffic Operator Position System (TOPS) Internet Protocol (IP) Security Enhancements

19.2 Description

This feature allows the customer to increase the security of the IP eXtended Peripheral Modules (IP-XPMs) in their TOPS-IP network. This feature introduces Succession core datafill which allows the customer to configure the following functions on the IP-XPM:

- Simple Network Management Protocol (SNMP): The customer can enable or disable SNMP, define an SNMP community name, and define an SNMP manager.
- Telnet: The customer can enable or disable Telnet.

These changes are discussed in more detail in the following sections.

19.2.1 Background

The implementation of TOPS-IP is based on the IP-XPM. The IP-XPM is a specialized Digital Trunk Controller (DTC) containing Ethernet-enabled SX05DA processor cards as well as 7X07AA Voice over IP (VoIP) gateway cards. The SX05DA and the 7X07AA each contain processor cards which can support various Internet applications including Ping, SNMP, Telnet, and more.

Nortel recommends that TOPS-IP be implemented on a secure network, not the public internet. A secure network contains subnets, firewalls, and routers which block unauthorized attempts to connect to a TOPS-IP node.

Security risks exist even if an IP-XPM resides on a secure network. For example, a malicious user could attempt to alter IP-XPM settings using SNMP. Another risk might be a user logging on to a 7X07AA card while the card is under heavy load. This action might cause the card to crash and calls to be lost.

This feature improves TOPS-IP security in the areas of SNMP and Telnet as described in the next sections.

19.2.2 SNMP

SNMP allows IP hosts to monitor, modify behavior, and receive unsolicited management information from other IP hosts. The monitoring host is termed the SNMP manager and the monitored host is termed the SNMP element. SNMP is described in several RFCs as follows:

- Version 1 (SNMPv1): RFCs 1155, 1157, 1212
- Version 2 (SNMPv2): RFCs 1441-1452, 1901-1910
- Version 3 (SNMPv3): RFCs 2271-2275

This feature proposes adding three new SNMP settings for TOPS-IP. The new SNMP settings are:

- **SNMP community name:** A character string which serves as a password when reading from or writing to an SNMP host.[1] This feature allows datafill of one community name up to 16 characters in length. The community name is used for reading and writing SNMP data. It is also used when the IP-XPM sends traps (unsolicited SNMP information) to an SNMP manager.

  This feature allows the community name to be set to some other value than "public." This increases security since hackers must guess the community name (through repeated attempts) or break into the secure network in order to use a sniffer to detect the SNMP community name.

  Many IP hosts allow configuration of different community names for SNMP reads, writes, and traps. For example, many users might need read access to a device while only a few need write access, so separate read and write names are defined. For TOPS-IP, SNMP support is limited, and it is not anticipated that many users will need access to SX05DAs and 7X07AAs. As a result only one community name can be defined.
- **SNMP manager:** An IP address specifying a remote host which is allowed to initiate SNMP requests to the IP-XPM. The SNMP manager is also called the trap manager, since it is the host to whom traps are reported. Allowing specification of an SNMP manager by IP address increases security, since the IP-XPM will reject SNMP write attempts from unauthorized remote hosts.
- **SNMP enable/disable:** A Y/N parameter indicating whether the IP-XPM supports any incoming SNMP requests, or sends out any traps.

The SX05DA and the 7X07AA support these settings as follows.

19.2.2.1 SNMP settings on SX05DA

The SX05DA supports limited SNMP capabilities, as detailed in "19.8 Appendix A: Supported SNMP objects on IP-XPM (SX05DA)" on page 170. The new SNMP settings apply to the SX05DA as follows.

- **SNMP community name:** The datafilled community name is validated for incoming read and write requests. The name is not sent in trap messages because the SX05DA does not send traps.

[1] In SNMP parlance, a read is a "get" and a write is a "set."

- **SNMP manager:** The SX05DA does not perform originating IP address validation when an SNMP write request is received. So there is no datafill for the SX05DA SNMP manager.
- **SNMP enable/disable:** By setting this parameter to N, the SX05DA will ignore all incoming SNMP requests. This parameter does not affect traps since the SX05DA does not send traps.

The SNMP community name and the SNMP enable/disable parameter are added as new fields in the tuples of existing Table XPMIPMAP. Table XPMIPMAP is used to configure the SX05DA cards on the IP-XPMs. Each tuple represents one IP-XPM. See the Configuration chapter of this document for the new field definitions.

The SNMP settings are datafilled in the Succession core, but the new settings do not take effect until the data is downloaded to the IP-XPM. The craftsperson must perform a LoadPM or Bsy/RTS on each unit to download the SNMP settings.

Dump and restore: Because SNMP is present on deployed IP-XPMs, the new fields are restored as follows when upgrading from an older TOPS Succession core load.

- **SNMP community name:** Restores as “public,” the default SNMP community name. “public” is also the name in use on currently deployed IP-XPMs.
- **SNMP enable/disable:** Restores to Y (SNMP enabled) since SNMP is enabled on currently deployed IP-XPMs.

19.2.2.2 SNMP settings on 7X07AA

The new SNMP settings apply to the 7X07AA as follows. These new settings apply only to TOPS 7X07AAs datafilled in existing Table IPINV (field `GW_TYPE` is set to `TOPS`).

- **SNMP community name:** The datafilled community name is validated for incoming read and write requests. The datafilled community name is also sent in trap messages.
- **SNMP manager:** Currently, up to 4 SNMP managers can be configured on a 7X07AA card. One is obtained via DHCP and up to three more can be configured using PMDEBUG on each card. This feature allows a fifth SNMP manager to be configured in the Succession core. When SNMP write requests arrive, the 7X07AA ensures the originating IP address is present in the allowed SNMP manager list. If not, the 7X07AA rejects the write operation.
- **SNMP enable/disable:** By setting this parameter to N, the 7X07AA will ignore all incoming SNMP requests and will not send any traps.

The new settings are added as individual office parameters in Table OFCENG. Each office parameter applies to all 7X07AAs in the office. See the Configuration chapter of this document for the new office parameter definitions.

The SNMP settings are datafilled in the Succession core, but the new settings do not take effect until the data is downloaded to the 7X07AA. The craftsperson must perform a PMRESET on each 7X07AA to download the SNMP settings.

Default values: These settings are implemented as office parameters which have default values of "public," no manager, and SNMP disabled, respectively.

Dump and restore: Because SNMP is present on deployed 7X07AAs, the new fields are restored as follows when upgrading from an older TOPS Succession core load with TOPS 7X07AAs present in Table IPINV.

- **SNMP community name:** Restores as "public," the default SNMP community name. "public" is also the name in use on currently deployed 7X07AAs.
- **SNMP manager:** Restores as N (no manager) since the 7X07AA currently has other methods of setting SNMP manager IP addresses.
- **SNMP enable/disable:** Restores to Y (SNMP enabled) since SNMP is enabled on currently deployed 7X07AAs. Note this differs from the default value of N.

19.2.3 Telnet (7X07AA only)

Telnet is a standard TCP-based service which allows a user to log on to a remote host and access the command line. Telnet is supported on the 7X07AA but not the SX05DA. Telnet is not recommended on a 7X07AA which is handling calls, since the use of Telnet or the use of CPU-intensive 7X07AA commands within a Telnet session can cause the card to crash, thus producing an outage.

Since Telnet is risky to use on an active 7X07AA, this feature allows Telnet to be disabled. This is done using a new office parameter in Table OFCENG. The parameter defaults to N meaning Telnet is disabled. See the Configuration chapter of this document for the new office parameter definition.

The new setting applies only to 7X07AAs datafilled for TOPS usage in existing Table IPINV (field `GW_TYPE` is set to `TOPS`).

The Telnet setting is datafilled in the Succession core, but the setting does not take effect until the data is downloaded to the 7X07AA. The craftsperson must perform a PMRESET on each 7X07AA to download the Telnet setting.

Dump and restore: Telnet is present and enabled on deployed 7X07AAs. But since it is such a risk, the new office parameter will restore to N (Telnet disabled) even if the TOPS-IP office has 7X07AAs defined in Table IPINV on the dump side. This is because it is likely that craftspersons do not use Telnet on a 7X07AA except for commissioning and debugging, and at other times Telnet presents the opportunity for an authorized craftsperson to cause an outage inadvertently.

19.3 Hardware Requirements or Dependencies

This feature does not introduce any new hardware requirements or dependencies.

19.4 Software Requirements or Dependencies

This feature requires new loads in the IP-XPM and in the NT7X07AA. These loads interpret and act on the SNMP and Telnet configuration data downloaded from the CM. The applicable loads are as follows:

- IP-XPM (SX05DA): QTP22
- 7X07AA: TGWYM004

19.5 Limitations and restrictions

19.5.1 IP-XPM (SX05DA) restrictions

The following existing IP-XPM restrictions are not changed by this feature.

- The SX05DA supports SNMPv1 and SNMPv2c only. The SX05DA does not support SNMPv2 or SNMPv3.
- The SX05DA does not validate the originating IP address of incoming SNMP write requests.
- The SX05DA does not send SNMP traps.
- The SNMP object values are not retained over a restart of the IP-XPM.
- The SX05DA does not support Telnet.

19.5.2 NT7X07AA restrictions

- The new parameters in Table OFCENG only have an effect on 7X07AA cards which are datafilled as TOPS cards in Table IPINV (field `GW_TYPE` is set to `TOPS`).
- The 7X07AA supports SNMPv1 and SNMPv2c only. The 7X07AA does not support SNMPv2 or SNMPv3. Please refer to the TOPS-IP User's Guide for further information concerning support of SNMP on the 7X07AA.

19.6 Interactions

Updated security settings do not take effect until they are downloaded to the SX05DA and 7X07AA using appropriate maintenance methods.

19.7 Glossary

Term	Description
7X07AA	VoIP cards which sit in an IP-XPM and act as a gateway between pulse code modulation (PCM) voice and packetized voice (VoIP)
Bsy	Busy, a maintenance command executed on DMS agents and peripherals
DHCP	Dynamic Host Configuration Protocol, an RFC2131-based method of configuring Internet hosts
DMS	Digital Multiplex System, the central Nortel switching processor
DTC	Digital Trunk Controller, an XPM for digital voice
IP-XPM	Internet Protocol eXtended Peripheral Module, a DTC-based XPM with Ethernet capability which provides the basis for TOPS-IP
LoadPM	Load Peripheral Module, a maintenance command executed on DMS peripherals
PMReset	Peripheral Module Reset, a maintenance command executed on DMS peripherals
RFC	Request For Comments, the standard method of documenting Internet applications
RTS	Return to Service, a maintenance command executed on DMS agents and peripherals
SNMP	Simple Network Management Protocol, described in “19.2.2 SNMP” on page 163
Succession core	An updated name for the DMS reflecting the addition of geographically diverse IP hosts serving a central processor (the core)
SX05DA	The processor card for the IP-XPM. Each unit of the IP-XPM has an SX05DA.
Telnet	A TCP-based tool for logging on to and executing commands on remote hosts
TOPS	Traffic Operator Position System, a system for providing operator services using operators and automation
VoIP	Voice over Internet Protocol, a method of sending voice over a packetized network

Term	Description
XPM	eXtended Peripheral Module, a device with its own processor sitting off the Succession core but providing essential services for the core

19.8 Appendix A: Supported SNMP objects on IP-XPM (SX05DA)

This section describes supported SNMP objects on the SX05DA.[1] The SX05DA supports Management Information Base II (MIB-II) as defined in RFC1213. The SX05DA also supports the User Security (USEC) basic group and USEC statistics from RFC1910 (User-based Security Model for SNMPv2).

The following two tables list SNMP objects supported by the SX05DA. MIB-II objects begin with the designation **iso.org.dod.internet.mgmt.mib-2** (numeric **1.3.6.1.2.1**). SNMPv2 objects begin with the designation **iso.org.dod.internet.snmpv2** (numeric **1.3.6.1.6**).

For definitions of these objects, refer to RFC1213 and RFC1910.

Read-write objects are check-marked in the R/W column. If there is no check mark, the object is read-only.

Restrictions apply as listed in section “19.5.1 IP-XPM (SX05DA) restrictions” on page 167.

Table 2: SX05DA support of MIB-II

Object name	Numeric name	R/W	Notes
system.sysDescr	1.1		
system.sysObjectID	1.2		
system.sysUpTime	1.3		
system.sysContact	1.4	3	
system.sysName	1.5	3	
system.sysLocation	1.6	3	
system.sysServices	1.7		
interfaces.ifNumber	2.1		

[1]Supported SNMP objects on the 7X07AA are already defined in the TOPS-IP User’s Guide.

Table 2: SX05DA support of MIB-II

20: Functional Description (FN): A00009012

20.1 Feature name and Feature ID

A00009012 - TOPS OSSAIN Service Enhancements

20.2 Description

This feature addresses a number of items to improve the OSSAIN functionality. It provides the following:

- The ability for an SN function to set the service of the call as it is being transferred or triggered.
- The ability for TOPSOPER and DASERV SN functions to indicate the call being transferred or triggered should be handled as a DA recall to increment the DA recall counter and populate operator messaging as needed.
- The removal of TOPSAUTO option AABS from table OAFUNDEF since AABS was EOL'd in a prior release.
- The support of MCCS for TOPSAUTO options in table OAFUNDEF to replace the default processing left by the AABS option. Since AABS could have still been datafilled, a call could route to AABS but fail since AABS was EOL'd - the call would then be routed to MCCS if available or operator if not.
- The replacement of ping usage in node audits and in the MAPCI command TST. Pings are not supported on certain platforms and are therefore replaced with an OAP message, Node Connectivity Test, as needed.
- The notification of OSSAIN Broadcast Announcements being EOL'd in SN10. The TEOL log will be generated whenever OSSAIN Broadcast Announcements are used.

Each of these areas is described in one of the following sections:

— SN Service for Transfers/Triggers

— DA Recall Support for OSSAIN

— AABS removal; MCCS support for OSSAIN functions

— OSSAIN Ping Replacement

— EOLing of OSSAIN Broadcast Announcements

— SOC and Table TOPSFTR for activation

20.2.1 SN Service for Transfers/Triggers

This portion of the feature enhances OSSAIN by allowing datafill to indicate what the service of the SN function should be for transfers and triggers.

20.2.1.1 Background

When an SN was allowed to offer DA service assistance, it was initially only designed to act like an ADAS/ADAS+ replacement to collect the city/name recording and perform the playback to an operator. The initial design did not anticipate a DA SN being able to fully automate a DA call nor provide service for DA recalls or transfers. Therefore, the switch assumes a DA call going from an operator to an SN must be going for call completion and switches the service to TA (along with cutting an AMA, changing the call origination, and resetting some billing parameters).

20.2.1.2 Enhancements

This feature provides datafill to override the switch assumptions in changing from DA to TA for operator to SN transfers. (If the service is not changed from DA to TA then the call origination will not change.) It also generalizes the ability of setting the proper service for an SN function to all transfers and triggers.

Table OAFUNDEF is enhanced to include two new options, one for the SN service and the other for generating AMA.

- The new SN service indicator datafill will be used for all transitions to an SN but not for initial call presentation. The scenarios include:
  - — Transfers from operator to SN
  - — Transfers from DAS to SN
  - — Transfers from SN to SN
  - — Triggers to SN
  - — Disposition Routing resulting in route to SN

20.2.1.3 Table OAFUNDEF: New Field USESERV

Note: The following illustrates the new look of table OAFUNDEF with this feature; however, each section will bold the new area it is discussing.

A new field, USESERV is added to table OAFUNDEF for calls transitioned to SN functions . When set to Y it indicates the service defined in ORIGSERV should be used for a call in transition (transfer, trigger, disposition routing).

Table 1 New Table OAFUNDEF

FUNCID	FUNCNAME	FUNCAREA
1	DA_SN	SN DASERV Y **N** N N N N Y CQ17 N
2	DA_TOPSOPER	TOPSOPER N OSSAIN_TO_DA_OPR N
3	TA_AUTO	TOPSAUTO MCCS 0_PLUS
4	TA_SN	SN TASERV **N** N N N Y Y CQ0 N
5	DA_SN_RCL	SN DASERV Y **Y** N N N N Y CQ17 N
6	DA_TOPSOPER_RCL	TOPSOPER Y OSSAIN_TO_DA_OPR N
7	TA_AUTO_RCL	TOPSAUTO MCCS 0_PLUS
8	TA_SN_RCL	SN TASERV **Y** N N N Y Y CQ0 N

- For a call in transition (transfer, trigger, disposition routing) to an SN function, the following processing occurs for the new field USESERV:if set to N, then existing functionality is maintained which means the service is maintained or switched DA to TA for operator to SN transfers
- if set to Y and the ORIGSERV is the same as the current service, then no changes are made to the call
- if set to Y and the ORIGSERV is different than the current service, then the service is changed and associated parameters reset as required with all service changes as noted in the OAP spec for service switches

Note: Whenever the OAFUNDEF option USESERV switches services, the same side effects occur as when an OAP Service Change Request is processed. Consult to OAP Specifications Document for details.

20.2.2 DA Recall Support for OSSAIN

This feature provides a datafillable means for OSSAIN to recognize a DA recall for calls which do not use the switch-based ARU structure for listing announcements. It will increment the DA recall counter and populate operator messaging as needed.

20.2.2.1 Background

A DA SN can offer listings via back-end announcements without using switch-based ARUs. The subscriber can initiate a recall from the announcement for an incorrect listing or for another listing. Transfers or triggers can be used to service the recall via an OSSAIN function. However, there is no mechanism provided for the SN or function to indicate this service is a recall service to mark recall counters to compare to switch limits as defined in table VROPT: maximum_da_recalls. Thus, if a call was serviced by an SN and then recalls to a TOPS operator, the call can exceed the maximum number of recalls defined in VROPT.

The vropt:maximum_da_recalls parameter was initially developed to limit the number of times a call can recall back to an operator to limit operator work time on one call. This parameter is not intended to track the number of listings. The maximum number of requested listings is datafillable in DATRKOPT field MULTREQ.

20.2.2.2 Enhancement

This feature provides datafill to note a DA recall via OSSAIN function to align SN and operator recall counts. It allows a method to count DA recalls processed by an operator and by an SN.

When the OSSAIN function is datafilled as a DA recall function, the DA recall counter is incremented and the OPP field, reason_for_operator, set to recall for proper processing at the position if the call routes to an operator.

The feature will also check if the maximum number of DA recalls has been reached prior to allowing the transition to the function. If the maximum DA recall limit has been reached and the call attempts to go to a DA recall function, then the call will be routed to treatment using the default_treatment of table OAINPARM, which is also used when the maximum number of transitions has been reached.

20.2.2.3 Table OAFUNDEF: New Field DARECALL

Note: The following illustrates the new look of table OAFUNDEF with this feature; however, each section will bold the new area it is discussing.

New field DARECALL is added in table OAFUNDEF to both TOPSOPER and DASERV SN functions. When set to Y, the count for DA recalls is incremented and, if going to an operator, the OPP field reason_for_operator is populated as recall.

Table 2 New Table OAFUNDEF

FUNCID	FUNCNAME	FUNCAREA
1	DA_SN	SN DASERV **Y** N N N N N Y CQ17 N
2	DA_TOPSOPER	TOPSOPER **N** OSSAIN_TO_DA_OPR N
3	TA_AUTO	TOPSAUTO MCCS 0_PLUS
4	TA_SN	SN TASERV N N N N Y Y CQ0 N
5	DA_SN_RCL	SN DASERV **Y** Y N N N N Y CQ17 N
6	DA_TOPSOPER_RCL	TOPSOPER **Y** OSSAIN_TO_DA_OPR N
7	TA_AUTO_RCL	TOPSAUTO MCCS 0_PLUS
8	TA_SN_RCL	SN TASERV Y N N N Y Y CQ0 N

Note: OAFUNDEF field DARECALL only applies to functions used in transfers and triggers. It is ignored for original services.

20.2.3 MCCS Support for OSSAIN Functions

This feature removes the AABS TOPSAUTO option from table OAFUNDEF datafill and adds the MCCS TOPSAUTO option.

Although AABS has been EOL'd, it was still possible for a call to route to the TOPSAUTO AABS datafill, fail AABS and then try to go to MCCS. Therefore, OSSAIN calls could route to MCCS in this manner. If the call was not eligible for MCCS then it was routed to an operator.

This feature maintains the existing functionality. Therefore, over an ONP, AABS will be replaced with MCCS and the call will route to MCCS instead of failing AABS first.

20.2.4 OSSAIN Ping Replacement

OSSAIN needs to replace ping (ICMP echo) functionality due to the following reasons:

— For security reasons, some customers may not allow ping in their Succession networks.

— Ping is not supported on some SOS platforms on which TOPS may be supported in the future.

SN07 activity A00005160 introduced the OAP Node Connectivity Test operation. The purpose of this operation is to verify application-layer connectivity between the switch and a service node. In SN07 and higher, OAP Node Connectivity Test messaging replaces ping in an OSAC remote in the RTS sequence for an OSN, if the OSN is at OAP 9 or higher and the OSAC host is at SN07 or higher.

This feature addresses the remaining situations in which OSSAIN has historically used pings - in audits and in the TST MAPCI command.

20.2.4.1 OSSAIN Audits

If an OSAC remote has not received a message from an in-service OSN for a datafilled time interval, it audits the OSN. Historically this audit has consisted of first a ping to the OSN and then, if a response is received, a Node Datafill Check Request to OSAC host. If the remote times out waiting for the ping reply, it retries a datafilled number of times.

With this feature, an OSAC remote at SN09 or higher uses the OAP Node Connectivity Test for the audit, rather than using ping, if the OSAC host is at SN07 or higher and the OSN is at OAP 9 or higher. Audit retries and time-outs are unchanged.

20.2.4.2 MAPCI TST Command

The `TST` command is available with an OSNM, OSN, or OSAC node posted at the MAP. A node must be ManB to be tested. The `TST` command has two variations which, prior to this feature, used pings - `TST` with no parameters and `TST` with the optional `PING` parameter.

- If `TST PING` is entered, the switch sends a ping request to the posted node and reports success on receipt of a valid reply. If it can't send the request or doesn't get a valid reply, it reports failure. This feature adds a new failure response, "Use TST without PING," which is displayed if the MAP user enters `TST PING` on a platform that does not support ping.

- If TST is entered with no parameters, the functionality prior to this feature depended on the kind of node being tested:
  - — OSNM - First did a ping test on the OSNM. Then if that succeeded, sent a Node Test Request to the OSNM.
  - — OSAC - First did a ping test on the OSAC node. Then if that succeeded, sent an OSAC Node Test Request to the OSAC node.
  - — OSN - First did a ping test on the OSN. Then if that succeeded, sent an OSN Node Datafill Check Request to the OSAC host.

  Notice that for OSNM and OSAC, the ping test was immediately followed by an OAP or OSAC message to the same node. The subsequent message also verifies connectivity. Therefore, this feature eliminates the redundant ping in the test sequence for OSNM and OSAC nodes.

  For OSN, the ping could not simply be removed from the test sequence because it is not followed by another message to the OSN. Therefore, for OSN nodes this feature substitutes a Node Connectivity Test request for the ping. This substitution occurs only if the OSAC remote is at SN09 or higher, the OSAC host is at SN07 or higher, and the OSN is at OAP 9 or higher.

20.2.5 EOLing of OSSAIN Broadcast Announcements

OSSAIN broadcast announcements will be EOL'd in SN10. A TEOL log will be generated in SN09 whenever OSSAIN Broadcast Announcements are used to indicate the functionality will be removed in SN10. The TEOL log will also be patched back to two prior releases.

20.2.6 SOC and Table TOPSFTR

A new entry in table TOPSFTR will control this feature's activation which will be tied to existing SOC option, OSAN0102: OSSAIN Enhancements. This new TOPSFTR entry will be called OSSAIN_RELEASE_22 to align with prior OSSAIN features.

The new entry will activate the call processing of the following portions of this feature (note datafill will be allowed regardless of this parameter):

- Transfer to SN function service
- DA Recall function

Table 3 Table TOPSFTR

FTRNAME	FTRENABL
OSSAIN_RELEASE_22	Y

20.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies.

20.4 Software Requirements or Dependencies

No special software requirements or dependencies.

Note: The OAP version is not increased by this feature since this feature does not change OAP.

20.5 Limitations and restrictions

- Although the DARECALL option in table OAFUNDEF could have been generalized to include TA recalls, TA recalls would apply to coin calls and since OSSAIN does not support coin at this time, this feature only supports DA recalls.
- Whenever the OAFUNDEF option USESERV switches services, the same side effects occur as when an OAP Service Change Request is processed. Consult to OAP Specifications Document for details.

20.6 Interactions

None

20.7 Glossary

No new terms are introduced with this feature.

21: Functional Description (FN): A00009013

21.1 Feature name and Feature ID

A00009013, TOPS announcements via UAS/AMS

21.2 Description

This activity provides the ability for Traffic Office Position System (TOPS) calls to use packet-based announcements. The functionality is available on Communication Server 2000 (CS 2000) with TOPS, in Succession hybrid offices with ENET and IP-based Succession solutions.

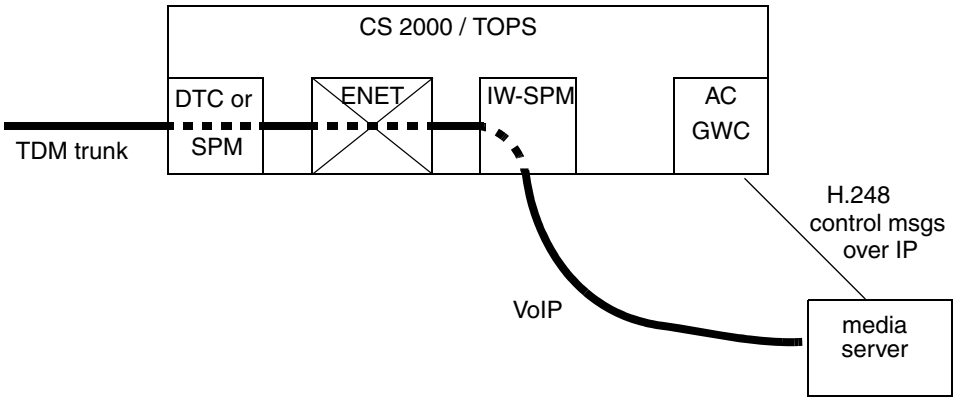
The packet announcement platforms that Nortel supports in SN09 for CS 2000 are the Media Server 2000 (MS 2000) Series and the older Universal Audio Server (UAS). The UAS is no longer sold, but this feature will work with it as long as Nortel supports it. The MS 2000 Series model used with IP bearer networks is the MS 2010.

In the Succession architecture, MS 2000 Series and UAS are special-purpose media gateways referred to as media servers. Each media server is controlled by a Gateway Controller (GWC) that is configured with the Audio Controller profile. An Audio Controller GWC can control multiple media servers, with the restriction that the same set of announcements must be provisioned on all the media servers that are controlled by the same GWC. The protocol between the GWC and the media server is H.248.

The operating company provides the voice recordings for packet-based announcements. Your Nortel or AudioCodes representative can refer you to professionals who provide this service. The web-based Audio Provisioning Server (APS) is used to provision the recordings on the media servers. Then CM datafill is entered in table ANNAUDID to associate the announcement phrase names known in the CM with the segment identifiers that were provisioned on the media servers. Other CM announcement tables are datafilled similarly for packet announcements as for legacy announcements.

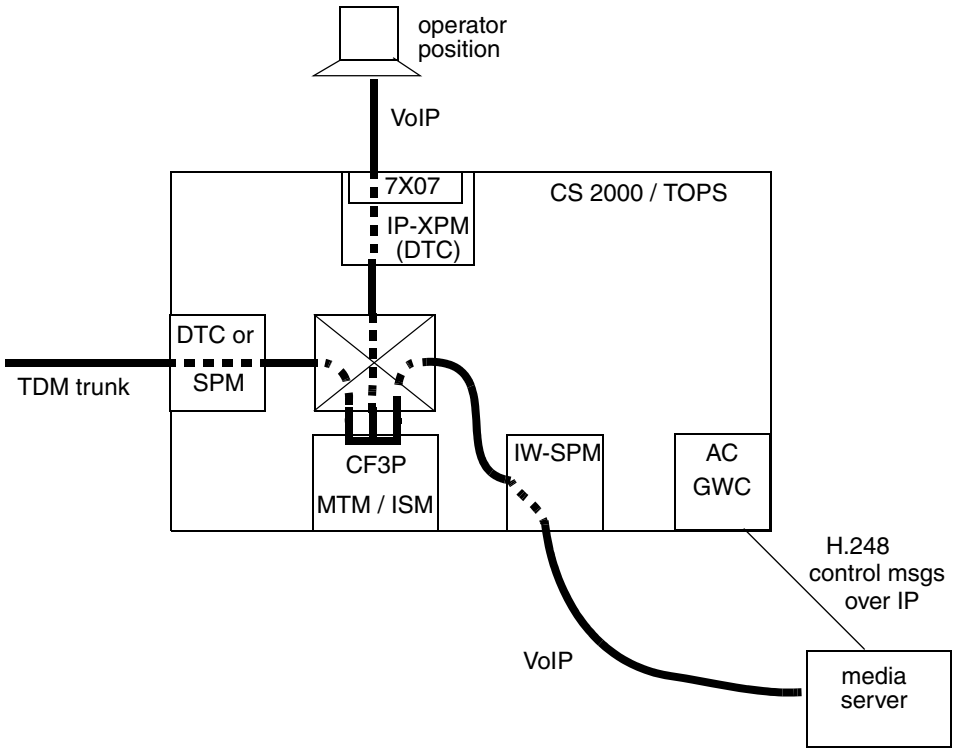
This activity does not change the restriction that calls can only enter the TOPS environment on legacy TDM trunks, and can only use legacy TDM conference resources. Therefore, an interworking bridge on an Interworking Spectrum Peripheral Module (IW SPM IP) is required for each TOPS call that connects to a packet announcement. The following figures show example topologies. The first example shows a TOPS call that has only the calling party connected to a packet-based announcement.

Figure 1 Legacy trunk connected to packet announcement



The next example shows a TOPS call that has an operator, a calling party, and a packet-based announcement.

Figure 2 Legacy conference connected to packet announcement



In both examples, the TDM trunk is any legacy PTS or ISUP trunk type that could originate calls to TOPS prior to this feature. It could be a looparound trunk, or it could connect to another office.

An announcement can have both legacy DRAM/EDRAM and packet members. If both legacy and packet members are available when a TOPS call needs an announcement, the CS 2000 automatically attempts to select a member whose network fabric matches that of the other agents on the call. Since all other agents on a TOPS call are connected to the ENET in SN09, this implies that legacy announcement members are always selected for TOPS calls if a legacy member is available. However, if only packet members are available, and if an interworking bridge is available, then a TOPS call will use a packet member and will automatically connect to it using the interworking bridge.

This activity supports TOPS use of packet announcements for the following functionalities:

- Branding
- Treatment
- Direct route to announcement via standard translations and routing
- Announcement segments of audio program for the Music and Announcement in Queue feature
- Automatic Coin Toll Service (ACTS)

  ACTS announcements are also used for the TOPS Time and Charges, Non-coin Notify, and ACTS Coin Tone Generation Test features. Those features can also use packet-based announcements.
- Mechanized Calling Card Service (MCCS)

  MCCS announcements are also used for the TOPS Sequence Calling, Account Code Billing, and Authorization Code features. Those features can also use packet-based announcements.

The functionality provided by this feature is automatically activated when packet members are brought into service for announcement groups that are used by TOPS calls.

This feature does not change the functionality of TOPS calls that use legacy DRAM/EDRAM announcements.

21.3 Hardware Requirements or Dependencies

This activity does not introduce new hardware. It uses hardware that is standard for CS 2000 IP hybrid with packet-based announcements.

21.4 Software Requirements or Dependencies

This functionality is first available in SN09. The software is also present in ISN09, but Nortel has tested it only with the North American load.

21.5 Limitations and restrictions

This activity does not add support for TOPS calls to connect directly with any kind of Succession agent other than announcements. Packet calls destined for TOPS in a CS 2000 must still arrive in the TOPS environment on legacy TDM trunks, using looparound facilities if needed to accomplish that.

This activity does not support packet-based announcements for TOPS custom announcement types TOPSVR and MDS. (TOPSVR is used for DRAM-based directory assistance and intercept announcements. MDS is used for the TOPS Message Delivery Service feature, also known as Audiogram Delivery Service. Note that most MDS functionality disappeared with end of life of the VSN.)

This activity does not support use of packet-based media servers for music segments of audio programs used by the Music and Announcement in Queue feature.

When packet-based announcements are used for MCCS and ACTS, the media server does not collect the DTMF or coin signals. Collection is still done by an MCCS or ACTS receiver card in an MTM/ISM.

An interworking bridge is required in SN09 for each TOPS connection to a packet-based announcement.

The functionality provided by this feature will not be supported in international (ISN) loads until it has been verified. At this time of this publication, Nortel planned to verify it only for North America.

The functionality provided by this feature will not be supported in ATM-based hybrid solutions until it has been verified. At this time of this publication, Nortel planned to verify it only with an IP network fabric.

This activity is subject to all of the limitations and restrictions that apply in general to CS 2000 use of packetized announcements. This includes the capacity limitations of media servers and Audio Controller GWCs. Some of the other important restrictions that this activity inherits from CS 2000 in SN09 are:

- Use of packet-based announcements is not supported if the CS 2000 connects two or more packet bearer networks. Note that a Trimodal CS 2000 connects two packet bearer networks, so packet announcements cannot be used on a Trimodal CS 2000. The restriction applies regardless of whether the two packet bearer networks have the same or different network fabrics.

- All of the media servers controlled by the same GWC must be provisioned with the same set of audio segments. Failure to follow this provisioning rule will result in call failures.

Please see the following section for additional interactions that could be viewed as limitations.

21.6 Interactions

The end user of a TOPS feature that uses announcements should detect virtually no difference in how the feature operates when packet-based announcements are used rather than legacy DRAM announcements. The one exception is that the media server may use different wording for certain variable phrases in custom announcements. The logic for the wording is in the media server, not in the switch. Specifically, when a time duration for ACTS is an even number of minutes, the switch instructs the DRAM to speak only "<x> minutes," but a packet media server may have logic to say "<x> minutes and zero seconds."

The MAXCYC field in CM table ANNS specifies the maximum number of times an announcement should repeat if the listening agent does nothing to terminate the connection. TOPS software has historically ignored the MAXCYC datafill for announcements played while a call is at an operator position or an OSSAIN service node. So, for example, if an operator requests to outpulse to a number and gets a treatment announcement, the announcement has historically continued to repeat itself until the operator keyed to release it. If the announcement member is a packet one, and if the operator does not key to release it before it has played the datafilled number of cycles, the announcement stops playing and the operator should key to release it at that time. The same is true for a packet announcement that is played to a call under control of an OSSAIN service node.

There are no interactions with the criteria by which an announcement is selected for a TOPS call. For example, the branding announcement CLLI for a TOPS call is selected based on criteria that may include the carrier or NBEC, the Service Provider ID (SPID), and datafill in several TOPS tables. All of this occurs before the announcement member is selected, and it happens independently of the network fabric of the member that will be selected.

21.7 Glossary

This activity does not introduce any non-standard terms or acronyms.

22: Functional Description (FN) A00009026

22.1 Feature name and Feature ID

RMGC Security.

Feature ID: A00009026

22.2 Description

The RMGC Security feature for the SN09 release will enable secure communications between the RMGC (or RMGC/Audio Controller) and the Multimedia Terminal Adapter (MTA).

Background

Small line gateways need to be provisioned with the address of their call processing (CallP) gateway controller (GWC) before they can provide service. Without an RMGC this must be done manually either in a configuration file downloaded to the gateway or directly on the gateway itself. This manual provisioning is difficult to manage and time consuming.

The RMGC serves as a registration agent that provides the gateways with a single location to obtain the fully qualified domain name (FQDN) (e.g., cms/gwc-08.iplab.gwsite-3.ny.net) of their associated CallP GWC. This simplifies the gateway provisioning. All gateways are provided with the RMGC FQDN. Each gateway will contact the RMGC before coming into service and the RMGC will redirect them to their controlling GWC.

Security

Many network deployments require the confidentiality, integrity, and authentication that is provided by Kerberos and IPSec services. When a Call Server 2000 (CS2K) network is deployed with security enabled, the components must all be secured. Prior to SN09 the RMGC (and Audio Controller (AC)/RMGC) combination were not secured.

In order to deploy an RMGC (or AC/RMGC) into a secure network it must be able to respond to requests from the MTA for secure associations (SAs). The method of establishing a SA is to use Kerberos for key management and Internet Protocol Security (IPSec) for secure connections.

The interaction between the MTA and the RMGC is straight-forward. Before coming into service the MTA will send an RSIP message to the RMGC. This RSIP message will initiate a SA negotiation with the RMGC. Kerberos will be used to negotiate an IPSec SA over which the RSIP is sent. The RMGC will respond with an RSIP redirect (over the SA) that contains the FQDN of it's associated CallP GWC. After this exchange the RMGC and MTA have no interaction until the next time that the MTA restarts.

Main Feature Items

The items that are addressed by this feature are:

- IPSec SA Management: The SAs that are used for the RSIP exchange between the RMGC and the MTA must have a short lifetime and must not be renewed. There are a large number of MTAs (maximum of 115,000) and the RMGC cannot maintain an SA database of that size.

- Memory Recovery: Even with the short lived SAs and no SA renewal enabled by this feature there is still a need to economize the memory usage since the high water mark for the SA storage is higher than that supported by the small lines profile.

- MTA Recovery: In order to maintain quick recovery times for the MTAs the CallP GWC must be modified slightly. In the case of a large restart event (like a power failure) the CallP GWC and restarting MTA must be able to re-establish contact without waiting for service from the RMGC, when possible.
The RMGC is modified to support multiple pools of SAs specifically to support the AC/RMGC combination profile. This ensures that the AC is able to setup secure connections when the RMGC is under heavy load.

To Provision an RMGC

The provisioning of the RMGC is very similar to that of a CallP GWC in that Kerberos and Connection Policies must be created. The only change is when a connection policy is created there is a limitation for the IPSec SA lifetime. This value must be between an upper and lower limit (10 seconds to 20 seconds). Any other value will not be accepted, the user will only be successful with the provisioning when this rule is conformed to.

22.3 Hardware Requirements or Dependencies

This feature can be deployed on the CEM-750 based GWC card in the SAM21 shelf.

This feature will function correctly on the CEM-905 GWC card as well. This configuration has not been tested but no issues are anticipated.

22.4 Software Requirements or Dependencies

This feature can be deployed in a dedicated (RMGC only) or combination (RMGC and Audio Controller) profile.

22.5 Limitations and restrictions

The user may only provision Kerberos-managed connection policies with a strict limit on the IPSec SA lifetime. If the user tries to create a connection policy with IPSec SA lifetimes that are outside of the range the connection policy will not be created and the user will be instructed to enter an acceptable lifetime.

22.6 Interactions

The behavior of the SA between the CallP GWC and it's associated MTAs will be different as a result of this feature. In a power failure or restart scenario the SA will be deleted from the CallP GWC in order to accelerate the recovery process. The user may detect this behavior if the number of SAs is being observed regularly.

23: Functional Description (FN) A00009027

23.1 Feature name and Feature ID

Global Network Product Support Trace Tool Enhancements

23.2 Description

Currently, GNPS and customer ability to trace protocol expression in a robust, complete manner within the GWC is limited to a handful of protocol, and is inconsistent. In addition, some new protocols (SIP and H.323) lack the ability to do an onboard trace which is not to screen.

To address this, the existing TAPITRACE tool will be enhanced to include the SIP and H.323 protocols and allow for better filtering and redirection of output. In addition, it will be better integrated with the SIP-Trunking tracing feature to better restrict per call captures (per feature A00003698: Razor Gateway requirement for Trunking).

An additional CALLTRAK SELECT will be introduced to allow inclusion of the calling and/or called DN. Currently, the SELECT command only supports DPT + CLLI (for SIP-T) or DPT + CLLI + CICs (for non SIP-T), which restricts tracing to the given DPT trunk.

After the intended changes are made, the SELECT command will allow selection per digits, given that these are the digits AFTER translations have occurred within the core:

SELECT DPT SIPT CGN <cgn_digits>
SELECT DPT SIPT CDN <cdn_digits>
SELECT DPT SIPT CGN <cgn_digits> CDN <cdn_digits>

It will also modify the existing option for enabling tracing within calltrak to allow tapitrace to be include in the capture as well. The old format:

TRMTRACE

will be changed:

GWCTRACE

and allow an optional parm to enable/disable tapitrace inclusion:

GWCTRACE TRACEOPTS on

Within the GWC, the TAPITRACE PMDEBUG level will add commands to filter based on protocol messaging contents and redirect messaging to the screen or an offboard trace tool without affecting call processing. These commands will be documented within the PMDEBUG command and will be consistent with existing interface.

23.3 Hardware Requirements or Dependencies

None.

23.4 Software Requirements or Dependencies

None.

23.5 Limitations and restrictions

The additional trace functionality above needs to have SIP routed through a NGSS for full traceability of SIP messaging.

23.6 Interactions

Interacts with the changes made to CALLTRAK by A00003698: Razor Gateway requirement for Trunking.

24: Functional Description (FN): A00009028

24.1 Feature name and Feature ID

A00009028 - CS2K MSM SIP Lines OAM Support

24.2 Description

This feature deals with meeting the OAM requirements on CS2K MSM for support of SIP Lines in release MCP 9.0. It is primarily concerned with the configuration of data corresponding to links to the CS2K and the maintenance on those links. All configuration will be done via the CS2K MSM Management Console; no flow through configuration is supported in this release. Once the link configuration is established the CS2K MSM components are responsible for initiating communication. Additionally, this feature provides for monitoring the registration state of SIP endpoints (CS2K MSM subscribers provisioned with a SIP Lines enabled service package) and performing a line test on the endpoint. This functionality will be accessible from the Management Console. Finally, Accounting will be disabled for the SIP Lines deliverable.

These requirements fall into the following work areas.

Non-Call Associated Signalling (NCAS) link for Querying SIP (QSIP)

Gateway Controller (GWC) link for Gateway Control Protocol (GCP)

Endpoint Maintenance

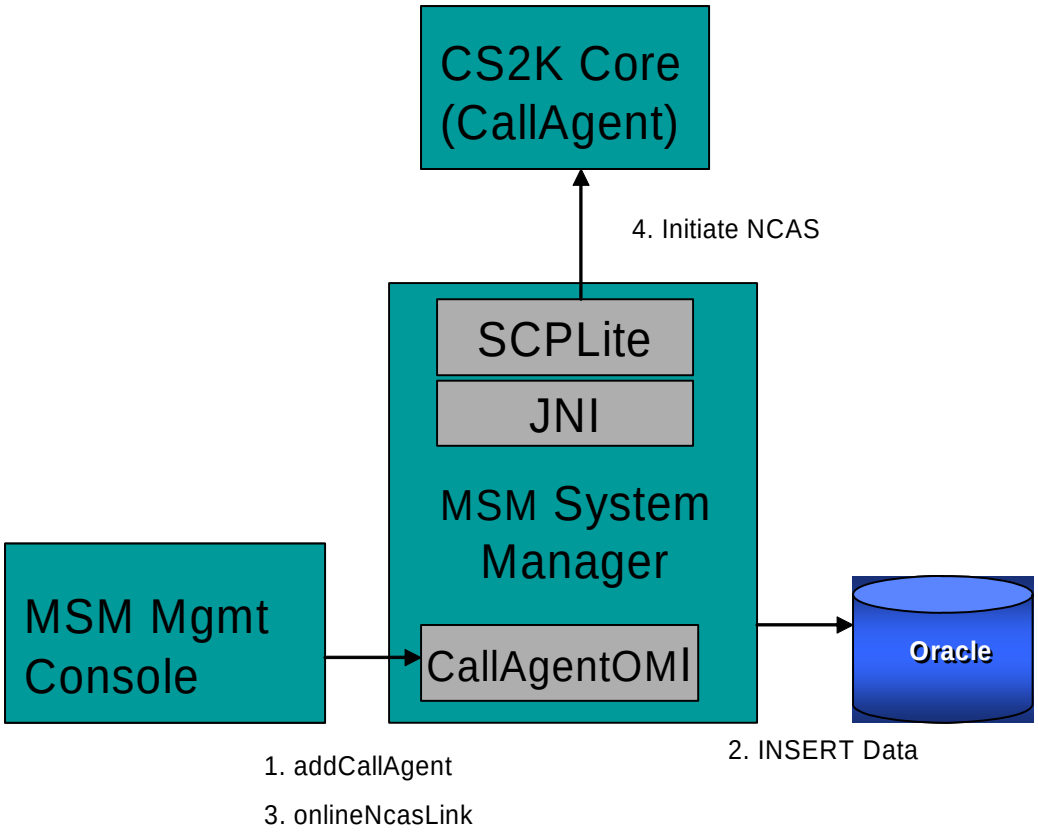
Disabling Accounting

24.3 NCAS Link for QSIP

This link will run between the CS2K MSM System Manager and the CS2K Core. Configuration of the link is provided via CallAgentData which contains a name (for database key purposes), an IP Address, and a port. Maintenance on this link will consist of setting a desired state to ONLINE or OFFLINE. The default state when the CallAgent data is added will be OFFLINE, requiring a manual maintenance action by the craftsperson at the Management Console to bring the link ONLINE. (See steps 1 and 3 in the diagram below.) In addition

to the desired state, the operational state of the link (CONNECTED or DISCONNECTED) will be reported at the Management Console.

Note: Screenshots of the Management Console will be made available in the Configuration section of this Design Document.



The OMI methods for configuring the CallAgentData are supported by the OMI service located at http://<sysMgrHost>:12121/axis/services/callagent as follows:

public void RuntimeResult addCallAgent(data CallAgentData)

public void RuntimeResult updateCallAgent(data CallAgentData)

public void RuntimeResult deleteCallAgent(key CallAgentNaturalKey)

public CallAgentData getCallAgent()

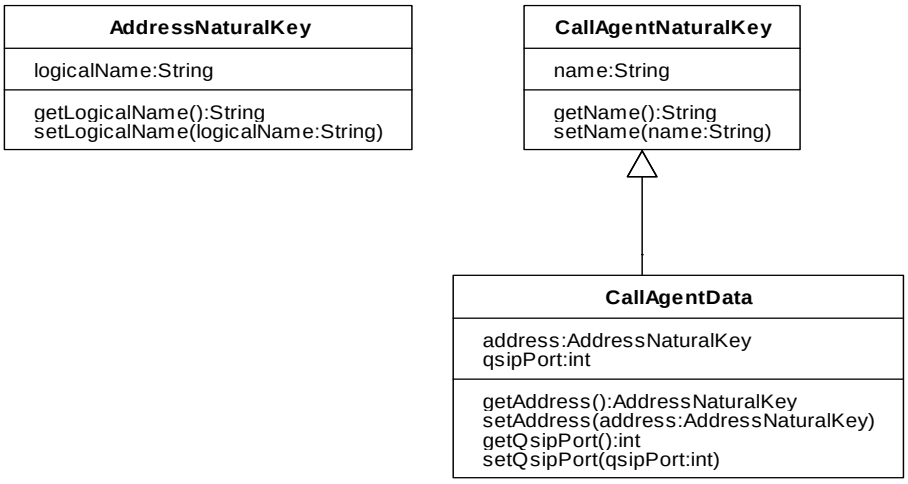


Table 1: CallAgent fields

Field Name	Description
AddressNaturalKey.logicalName	1-16 characters no spaces
CallAgentNaturalKey.name	1-32 characters [Aa-Zz][0-9][-.]
CallAgentData.qsipPort	Integer in the range 4900-4982

The local end of the NCAS link is defined at an offset of 25 from the base port of the System Manager. The address used will be the System Manager's Service Address, if configured, and if not, the Interface One address of the Server on which the System Manager resides.

Maintenance on the NCAS link is provided at the Management Console under the System Manager. The state of the link (CONNECTED, DISCONNECTED) is displayed. The actions to ONLINE or OFFLINE the link will be offered. Note that when the System Manager starts up, it will read the current desired state from the database to determine whether to initiate communication.

The OMI service is located at http://<sysMgrHost>:12121/axis/services/ncasmtc. The methods are are as follows:

public long startNcasLinkMonitor()

public RuntimeResult stopNcasLinkMonitor(long tid)

public NCASLinkStateData getNcasLinkNextState(long tid)

public String[] getNcasLinkAdminStates()

public String[] getNcasLinkOperationalStates()

public RuntimeResult rtsNcasLink()

public RuntimeResult offlineNcasLink()

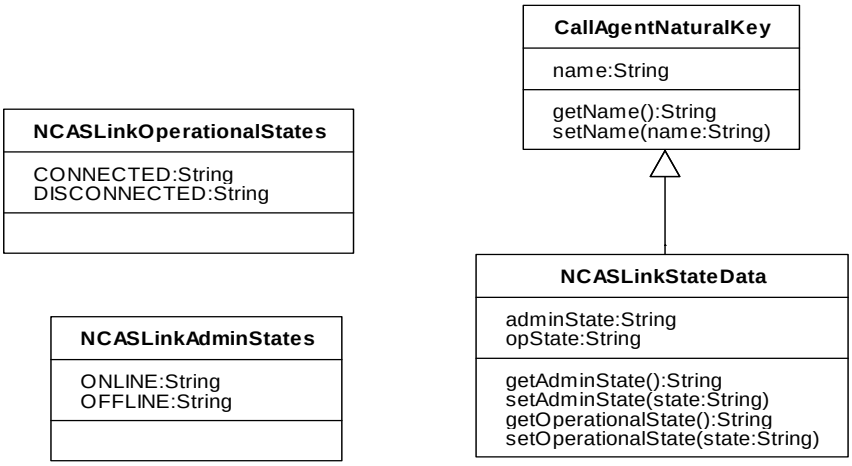

Table 2: NCAS Link State Data

Field	Description
adminState	String. Must be one of the values available from getNCASLinkAdminStates()
opState	String. Must be one of the values availabe from getNCASLinkOperationalStates()

Table 3: NCAS Link Operational States

Operational States
CONNECTED
DISCONNECTED

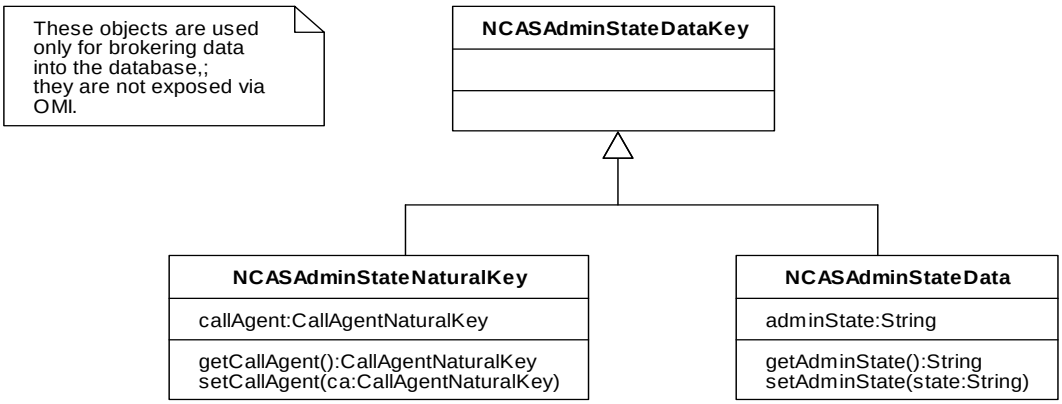
Table 4: NCAS Link Administrative States

Administrative States
ONLINE
OFFLINE

To support the additional data in the Oracle database, two new tables are added. The first contains the configuration data: CS2K_CALL_AGENT consists of three fields, NAME, ADDR and QSIP_PORT. NAME is a 32 character VARCHAR field, restricted to alphanumeric characters. ADDR is a reference to an Object Identification (OID) from the IP_ADDRESS table. QSIP_PORT is an integer field, restricted to the range 4900 and 4982.

> ***Note:*** All CS2K MSM configuration tables contain an implicit OID column created by the data access framework. This column will not be explicitly named for each table, but will be assumed to be present for foreign key use.

The second stores the administrative state: CS2K_CALL_AGENT_ADMIN_STATE consists of two fields. CALL_AGENT is a contextual foreign key into CS2K_CALL_AGENT. ADMIN_STATE is a 16 character VARCHAR, to contain “ONLINE” or “OFFLINE”.

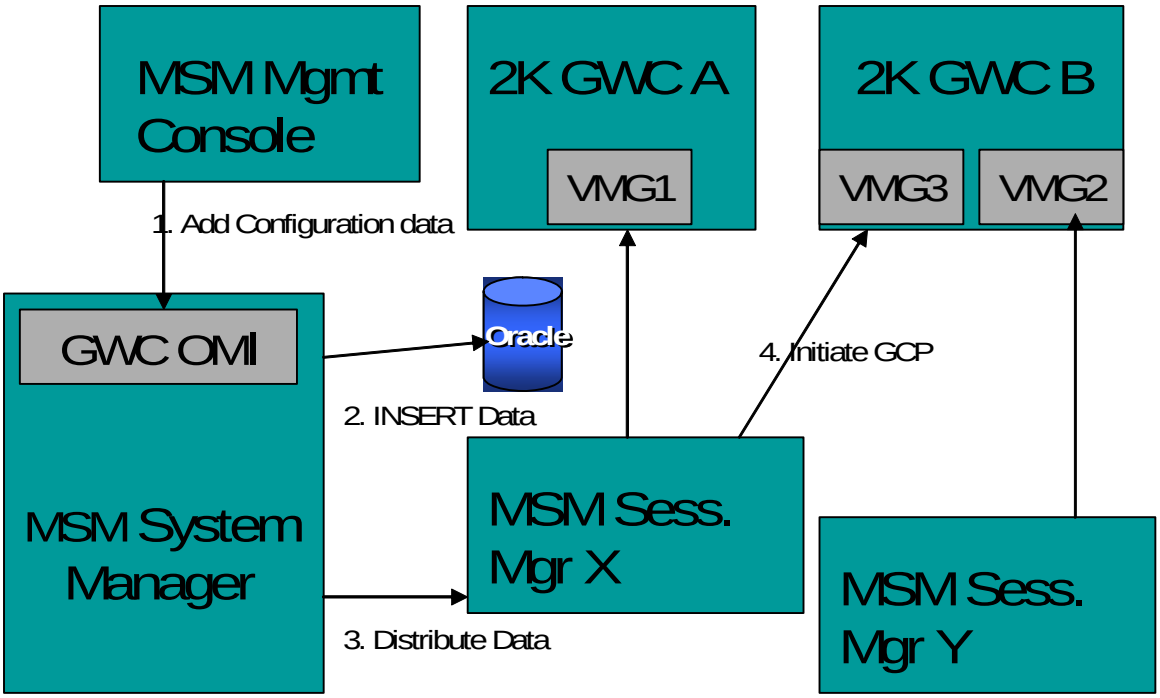


In addition to the configuration and maintenance of the link, enhancements to the Event Distribution framework allow the QSIP coming into the System Manager over NCAS to be answered by request to the active instance of the responding CS2K MSM Network Element (NE). A boolean indicating that only the active instance of an NE is to receive the request is added to the internal event, and is used by the Event Distribution system to determine destination.

24.4 GWC Configuration and Maintenance

A call processing link shipping Gateway Controller Protocol (GCP) over UDP exists between the CS2K MSM Session Manager and the CS2K Gateway Controller (GWC). It's configuration is somewhat more complex than that of the NCAS link, because the relationship between Session Manager and GWC may not be one to one, and further, the relationship is viewed from the GWC side through a Virtual Media Gateway (VMG), which is required for Subscriber provisioning (discussed in detail in A00009043 - SIP Lines Provisioning Support).

The diagram below describes an example of how GWCs and Session Managers might be associated via VMGs. The diagram depicts a configuration given GWCs A and B and Session Managers X and Y. Session Manager X appears as VMG1, tied to GWC A and Session Manager Y appears as VMG2, tied to GWC B. The flow shows the association of VMG3 with Session Manager X. When the association is made, Session Manager X initiates a GCP message to GWC B.



The GWC data is Network Level data shared across all Network Elements. VMG appearances are specific to the Session Manager, and appear only on the appropriate Session Manager. The GatewayControllerData is configured through the OMI service located at http://<sysMgrHost>:12121/axis/services/gwcconfig. The signatures of the OMI methods are as follows:

public void RuntimeResult addGatewayController(data GatewayControllerData)

public void RuntimeResult updateGatewayController(data GatewayControllerData)

public void RuntimeResult deleteGatewayController(key GatewayControllerNaturalKey)

public GatewayControllerData[] getGatwayControllers()

public GatewayControllerNaturalKey[] getGatewayControllerNaturalKeys()

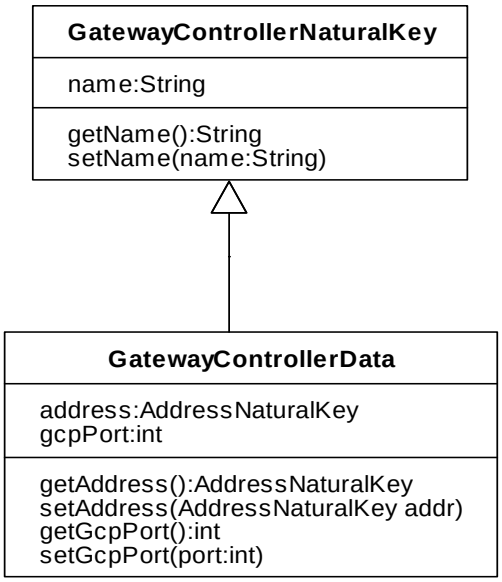


Table 5: Gateway Controller Data

Field	Description
name	Of the form gwc-### where ### may be any integer in the range 0-255, and the characters “gwc-” are fixed
gcpPort	Integer in the range 0-65534

For configuring the VMG the service at http://<sysMgrHost>:12121/axis/services/vmgconfig contains the following methods:

pubic void RuntimeResult addVmgAppearance(ctxt SessMgrNaturalKey, data VMGAppearanceData)

public void RuntimeResult deleteVmgAppearance(ctxt SessMgrNaturalKey, data VMGAppearance)

public VMGAppearanceData[] getVmgAppearances(ctxt SessMgrNaturalKey)

public VMGAppearanceNaturalKey[] getVmgAppearanceNaturalKeys(ctxt SessMgrNaturalKey)

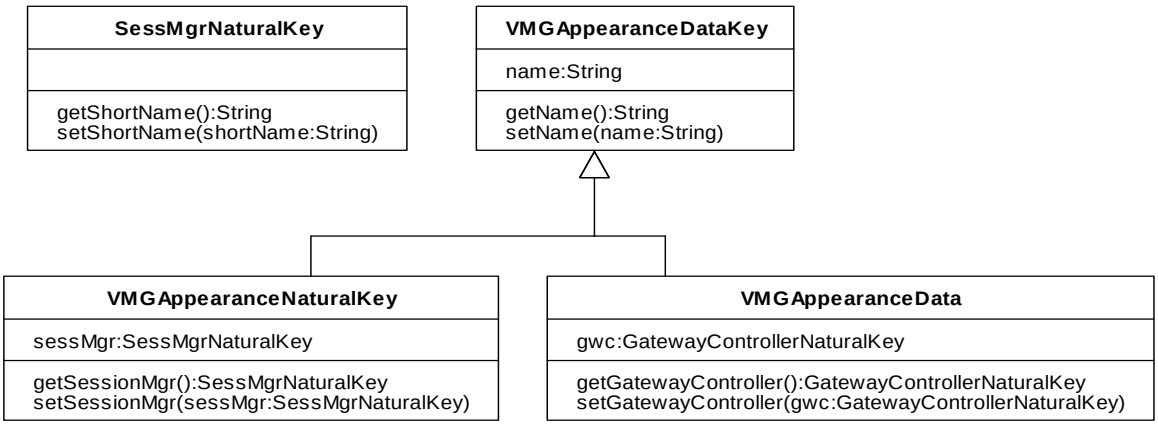

Table 6: VMG Appearance Data

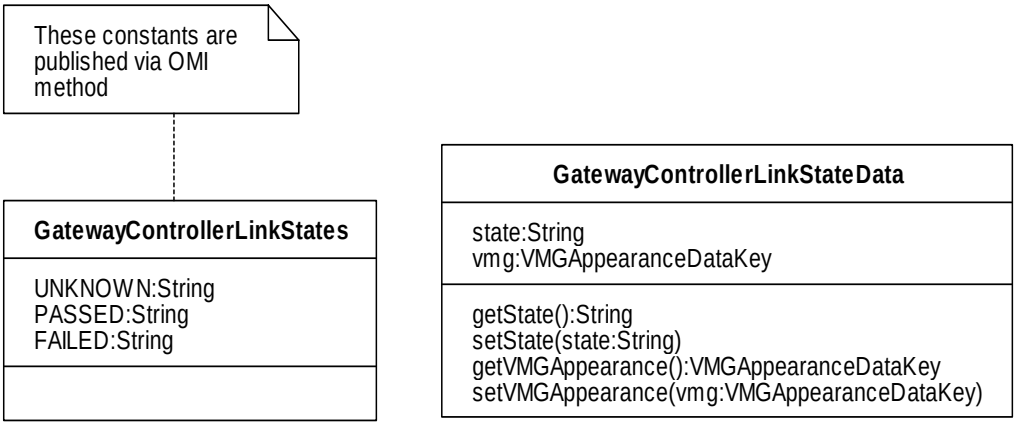
Field	Description
SessMgrNaturalKey.shortName	1-6 characters spaces, dots and underscores for-bidden
VMGAppearanceDataKey.name	1-32 characters [Aa-Zz][0-9][-.]

Maintenance on the links to GWC from Session Manager is available via the Management Console, under each Session Manager. Since the link is over UDP, the only available maintenance command is a line test.

The OMI methods for GWC link test are available through the service located at http://<sysMgrHost>:12121/axis/services/gwcmtc:

public GatewayControllerLinkStateData[]
testGatewayControllerLink(SessMgrNaturalKey ctxt,
VMGAppearanceDataKey[] keys)

public String[] getGatewayControllerLinkStates()



Starting the Gateway Controller Link State maintenance application at the Management Console for a given Session Manager will result in an initial test on the GWC links. Subsequent manual tests of each GWC link are allowed via a test button

Table 7: Gatway Controller Link State Data

FAILED

Table 9: The operational states of the GWC Link

Link States
UNKNOWN
PASSED
FAILED

The configuration requires the addition of two new tables to the Oracle database.The first allows the configuration of GWCs, the second the association of a Session Manager with a GWC via a VMG name.

The CS2K_GWC table contains three fields, NAME, ADDR, and GCP_PORT. NAME is of the form gwc-###, where ### is numeric from 0 to 255, giving a VARCHAR of length 7. ADDR is a reference to an Object Identification (OID) from the IP_ADDRESS table. GCP_PORT stored as an integer, between 0 and 65534.

The CS2KVMG_APPEARANCE table contains three fields, NAME, GWC and a contextual field SESSION_MGR. NAME is a VARCHAR(64) which is globally unique.This name will be used when the Subscriber association with the VMG. is made on the Provisioning Server. GWC is a reference to an OID from the CS2K_GWC table. SESSION_MGR is a reference to an OID from the SESS_MGR table.

Because the VMG is configured and the association of VMG with Subscriber is is provisioned, the use of a VMG associated with the correct server home (Session Manager) is enforced when a Subscriber is added or updated. VMGs may not be deleted while some subscriber is still associated with the VMG.

24.5 Endpoint Monitoring

This feature treats a CS2K MSM subscriber as a SIP Line. Subscribers have dynamic state: OFFLINE, IDLE, and CPB. This information (along with other subscriber data) will be available via a QSIP query over the NCAS link as discussed in section 2.3. Additionally, it will be available from the Management Console as a direct query to the Session Manager to which the subscriber is homed. Also from the Management Console, a maintenance ping can be sent to the subscriber endpoint via an OPTIONS message as a line test,

resulting in a line state. The line test functionality is available only through the Management Console. To limit network traffic, the number of lines which can be simultaneously monitored at a single Management Console is limited to five.

The state of a SIP Line is dynamic and is not stored in the Oracle database by the configuration system. Given this, a query must be made to find the subscribers before monitoring can be initiated. The query may be made by DN or by Subscriber name in the format name@domain. After a user is posted, it may have a line test done on it. The line test will test all devices provisioned against the subscriber in addition to all currently registered devices. The two sets of devices may overlap, and the result will contain data for the superset. The result will indicate for each client whether any response was received, as well as an overall indication of whether all clients responded, some clients responded, or no clients responded.

The OMI methods to monitor and maintain the SIP line are available at http://<sysMgrHost>:12121/axis/services/endpointmtc.

public SubscriberData[] getSubByDirectoryNumber(String dn)

public SubscriberData[] getSubByName(String name)

public long startEndpointStateMonitor(SubscriberNaturalKey[] keys)

public RuntimeResult stopEndpointStateMonitor(long tid)

public RuntimeResult updateEndpointStateMonitor(long tid, SubscriberNaturalKey[] keys)

public EndpointStateData[] getEndpointNextState(long tid)

public EndpointLineTestStateData[] testState(SubscriberNaturalKey[] keys)

public String[] getEndpointStates()

public String[] getEndpointLineStates()

The data returned by the subscriber queries:

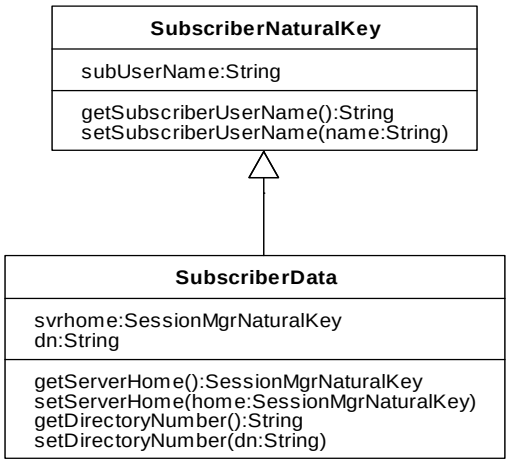

Table 10: Subscriber Data

Field	Description
userName	String of the form <user>@<domainname> where user and domain name each consist of 1-64 alphanumeric characters
dn	String containing 4-18 decimal digits.

The data returned by a line state monitor.

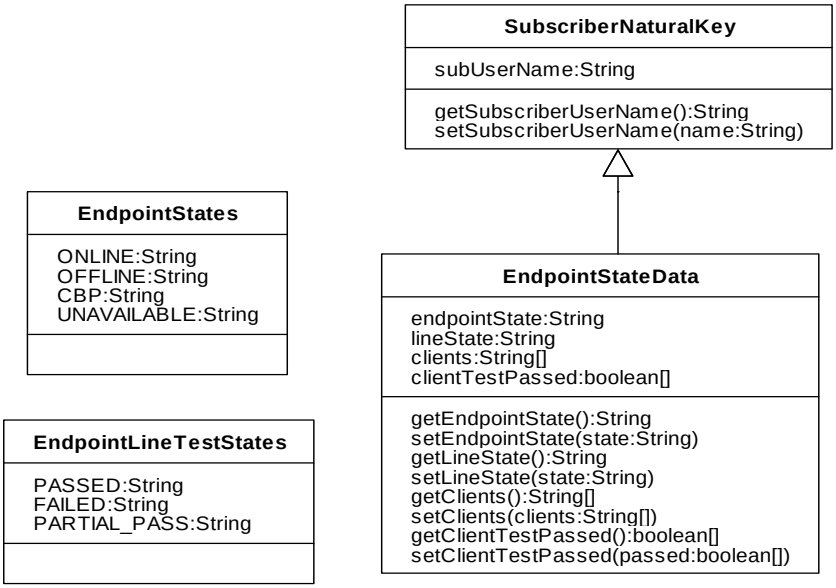

Table 11: Endpoint State Data

Field	Description
endpointState	String. Required to be one of the values available from getEndpointStates
lineState	String. Required to be one of the values available from getEndpointLineStates
clients	Array of strings describing the clients of the subscriber.
clientTestPassed	Array of booleans corresponding to the clients array, and indicating whether each client passed the line test (true=passed, false=failed)

Because acquiring the state of a line requires going to the Session Manager where the endpoint is homed, and that Session Manager may not be accessible from the System Manager, the UNKNOWN state is introduced to the list of displayed Additionally, since the line state is not automatically tested, it’s

initial displayed state is NOT_RUN. A PARTIAL_PASS exists when at least one, but not all of a subscriber's clients can be reached by the line test.

24.6 Disable Accounting

This feature allows MCS accounting functionality to be disabled. When accounting is turned off, no Accounting Manager (AM_ will be configured against the Session Manager, and no billing records will be spooled. This feature changes the SESS_MGR table to allow NULL in the AM column. The Management Console provides a selection value of <none> in the AM combo box to support this configuration.

When the AM is set to null, no billing records will be spooled by the recording framework. When the AM is not set to null, billing records will be spooled and sent to the AM.

24.7 Hardware Requirements or Dependencies

Not Applicable.

24.8 Software Requirements or Dependencies

Dependant on SCPLite for NCAS link.

24.9 Limitations and restrictions

NCAS Link for QSIP

Support for a single NCAS link to a single CS2K Core at a time is provided. Therefore, only a single CallAgent can be configured at a time.

Updates to the IP address or port of the CallAgent are allowed only if the CallAgent is in the OFFLINE state.

GWC Link

VMG Appearances can only be added and deleted, not updated.

Global uniqueness is enforced across VMG names

Endpoint Monitoring

A maximum of 5 endpoints can be simultaneously posted from a single Management Console

24.10 Interactions

A00009043 SIP Lines Provisioning Support

A00007544 - NCAS link for service control

A00007545 - GCP to SIP conversation on FPF

24.11 Glossary

Term	Description
Accounting Manager	CS2K MSM component which formats and stores billing records from the Session Manager. Turned off in MSM 9.0
AM	Accounting Manager
CPB	Call Processing Busy. Used to indicate that a SIP Line Subscriber is in the middle of a call.
Endpoint	Refers to a SIP Line Subscriber. In the context of SIP Lines, an endpoint does not actually refer to an IP port pair, but to a subscriber who may have registrations at multiple locations.
GCP	Gateway Control Protocol. Used for communication with GWCs

Term	Description
GWC	Gateway Controller. CS2K component to which Session Managers communicate for call processing
MCS	Multimedia Communication Server
MSM	Multimedia Session Manager
NCAS	Non Call Associated Signalling
NE	Network Element. A managed component of CS2K MSM. Includes Accounting Manager, Session Manager, and System Manager.
OAM	Operations, Accounting, and Management.
OID	Object Identifier. Unique ID used in the CS2K MSM database as a primary key.
OMI	Open Management Interface
Provisioning Manager	CS2K MSM component which manages CS2K MSM provisioning, including subscribers.
Session Manager	CS2K MSM component which manages SIP Sessions and call processing
SIP	Session Initiation Protocol
System Manager	CS2K MSM component which manages CS2K MSM configuration and maintenance.
VMG	Virtual Media Gateway. CS2K view of the CS2K MSM Session Manager.

25: Functional Description (FN): A00009036

25.1 Feature name and Feature ID

SN09: A00009036 - Table HOMELRN Option SITE Expansion

25.2 Feature Background

Local Number Portability (LNP) allows users to change local service providers and yet retain their current 10-digit directory number (DN). Location Routing Numbers (LRNs), not DNs, are used to identify the switch serving a ported subscriber.

LRNs are used for routing and billing purposes and are associated with host and remote switching units via table HOMELRN. Table HOMELRN uses the SITE option to assign SITE (remote switching unit) names for a particular non-HOST LRN entry in the table.

To accommodate succession office collapse solutions there is a need to provision more than the current maximum of 10 SITE names that may be associated with a single LRN entry. This activity expands the maximum number of SITE names that can be assigned to the SITE option for an LRN entry in table HOMELRN from 10 to 256.

25.3 Feature Description

This activity affects the provisioning of LRNs for remote switching units in Table HOMELRN. Remote switching units are defined by entries in Table SITE. Prior to SN09, a maximum of 10 SITE names can be associated with a particular LRN entry in Table HOMELRN using the SITE option. This activity allows a maximum of 256 SITE names to be associated with a particular LRN entry in Table HOMELRN using the SITE option.

The option SITE enables multiple site names to be associated with a single LRN. The supported site names are valid names provisioned in Table SITE(i.e. HOST, REM1, REM2,. etc.). The maximum number of SITEs in one tuple is expanded to 256. Once the maximum number of SITE names has been entered for an LRN entry, HOMELRN table control stops prompting for additional SITE names as was done for the prior limit of 10. Other than the new (256) maximum limit for SITE names per HOMELRN entry, there are no other changes to the provisioning capabilities of table HOMELRN.

An external view of the table HOMELRN changes is shown in See “Table HOMELRN Option SITE Entry Changes” on page 218..

Figure 1 Table HOMELRN Option SITE Entry Changes

Old Maximum - Up to 10 SITE Names per LRN Example:

TABLE: HOMELRN
AREACODE OFCCODE STNCODE OPTIONS
---
312 858 $ (SITE (REM1) (REM2) (REM3) (REM4) (REM5) (REM6) (REM7) (REM8) (REM9) (REM10) $)**$**

New Maximum - Up to 256 SITE Names per LRN Example:

TABLE: HOMELRN
AREACODE OFCCODE STNCODE OPTIONS
---
312 858 $ (SITE (REM1) (REM2) (REM3) (REM4) (REM5) (REM6) (REM7) (REM8) (REM9) (REM10) **(REM11) (REM12) (REM13) (REM14) (REM15) (REM16) (REM17) (REM18) (REM19) (REM20) (REM21) (REM22) (REM23) (REM24) (REM25) (REM26) (REM27) (REM28) (REM29).....(REM57).....(REM127)..... ..... (REM208).....(REM256)** $)**$**

Note: This capability is NOT under Software Optionality Control (SOC). This capability is an enhancement to LNP00100 functionality.

25.4 Hardware Requirements or Dependencies

There are no hardware requirements or dependencies associated with this functionality.

25.5 Software Requirements or Dependencies

There are no software requirements or dependencies associated with this functionality.

25.6 Limitations and restrictions

No more than 256 SITE names can be associated with an LRN entry in table HOMELRN.

25.7 Interactions

None

LRN	Location Routing Number
SOC	Software Optionality Control

26: Functional Description (FN): A00009043

26.1 Feature name and Feature ID

A00009043: CS2K SS SIP Lines Provisioning Support

26.2 Description

The SIP Lines product leverages existing CS2K SS SIP features and CS2K Centrex features. This feature provides the capability to provision data required by CS2K SS for the SIP Lines product for the MCP 9.0 release. Provisioning support that will be provided involves the ability to provision data such as subscriber or SIP end point information used by the Session Manager to provide SIP services.

The following items will be introduced into CS2K SS

- SIP Lines as a service called CS2000 SIP Line
- SIP Lines attributes to the subscriber

The Provisioning of the SIP Line data will be available via both the Provisioning Client and via OPI. OPI is the Open Provisioning Interface, a web service which gives the ability to provision data required on CS2K SS in return for services that it can provide. OPI's capabilities are available via a published WSDL using which the provisioning activities that are required can be determined. For more information on OPI, please refer to the OPI Specification document. Details on the Provisioning Client, which is a GUI based provisioning interface are available in the Provisioning Client User Guide.

26.3 SIP Line data

The data required for SIP Lines primarily consists of:

- End point id
- Virtual media gateway
- Client Type
- Directory Number

In addition to this on the CS2K SS, a new service will be introduced which will qualify a subscriber to be a SIP Line subscriber. All the above mentioned information in addition to a service package containing the new service will be associated to subscribers using which SIP Lines services will be processed.

A more detailed description of the data introduced is given below:

Field Name	Description
End Point Id	Format: <SITE>/<FFF>/<G>/<TTtt> <SITE> = 1-4 Alphanumeric characters. Corresponds to provisioned SITE name in the XACore. <FFF> = 000-511 Corresponds to the frame number used in the logical group name in the XACore. <G> = 0-9 Corresponds to the group number used in the logical group name in the XACore <TTtt> = 0000-1022 Corresponds to the circuit numbers (upper and lower) in the LENs defined against the logical group in the XACore. This is a globally unique field that the user is associated with Maximum length 15 characters; valid character set [Aa-Zz][0-9][/]
Virtual Media Gateway	Virtual gateway name used in GWC provisioning. Maximum Length 64 characters valid character set [Aa-Zz][0-9][-./]
Client Type	This is required for determining if the user has a device that can be queried. The supported client types are: Optical Network Terminator or ONT. If there is no client then the user will not be queried for a device on a line test
Directory Number	This is a globally unique number that is associated with a subscriber, similar to user aliases.

Note: Because of a restriction on the CS2K Session Server in the way the directory number is stored, the username part of the user, i.e. the string before the @domain, cannot be the same as the directory number. This restriction will be taken care of in future release, which will allow both to be same and hence easier to identify.

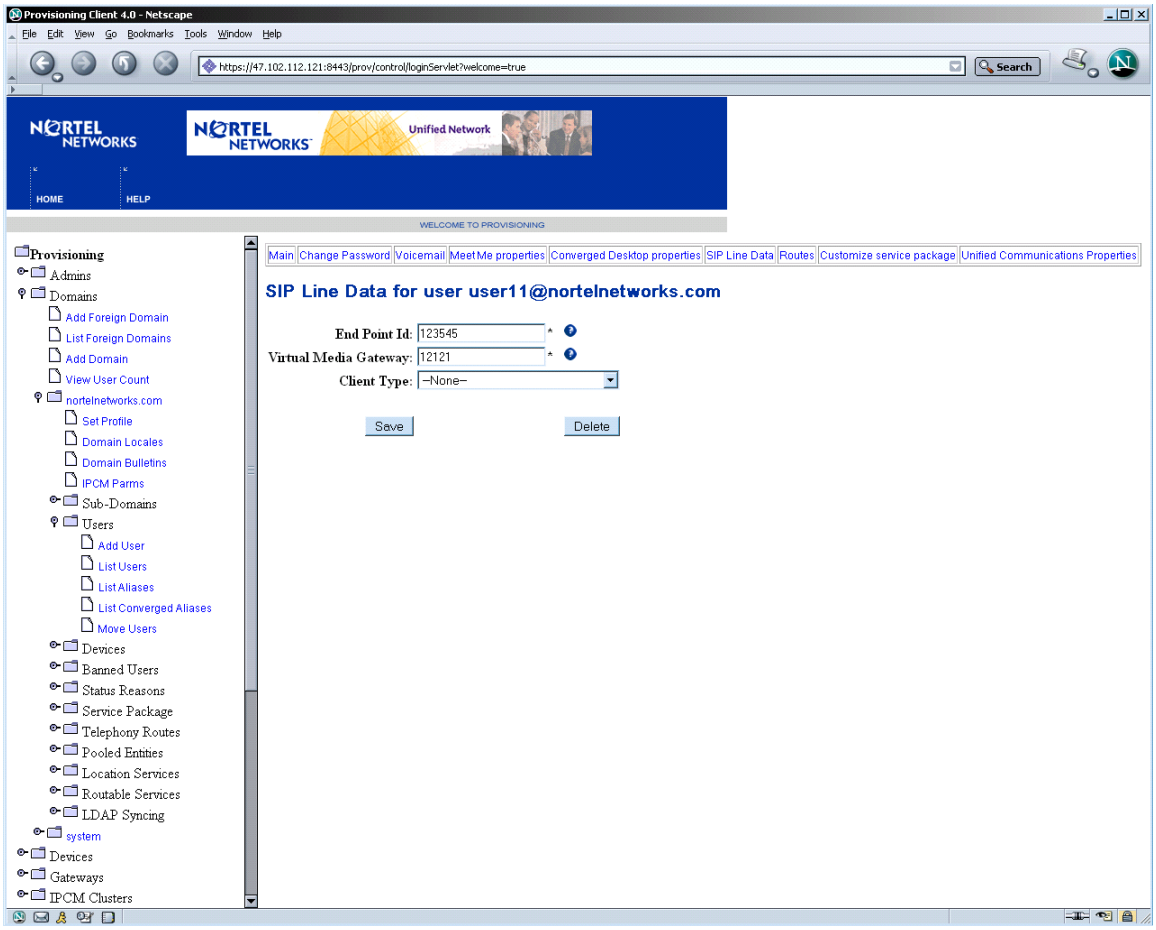

Figure 1 SIP Line Data provisioning for a user from Provisioning Client

Virtual Media Gateways are associated to Session Managers and also to a subscriber. Subscribers are homed on a session manager via the server home attribute associated to the domain that the subscriber belongs to. In case there is a change in the session manager of a domain, then the virtual media gateway information associated to a subscriber is no longer valid. In this scenario the following needs to be done to associate the subscriber to the correct virtual media gateway.

For each SIP Lines subscriber, going though SESM:

- change the end point id on the core
- change the end point id and the VMG via OPI

While changing the server home there will be no check to determine subscribers associated to it

Directory number is a new field associated to the subscriber which is exposed via OPI.

Additional types of clients supported for SIP Lines can be added to CS2K SS via OPI and the Provisioning Client. This interface is shown in the next figure.

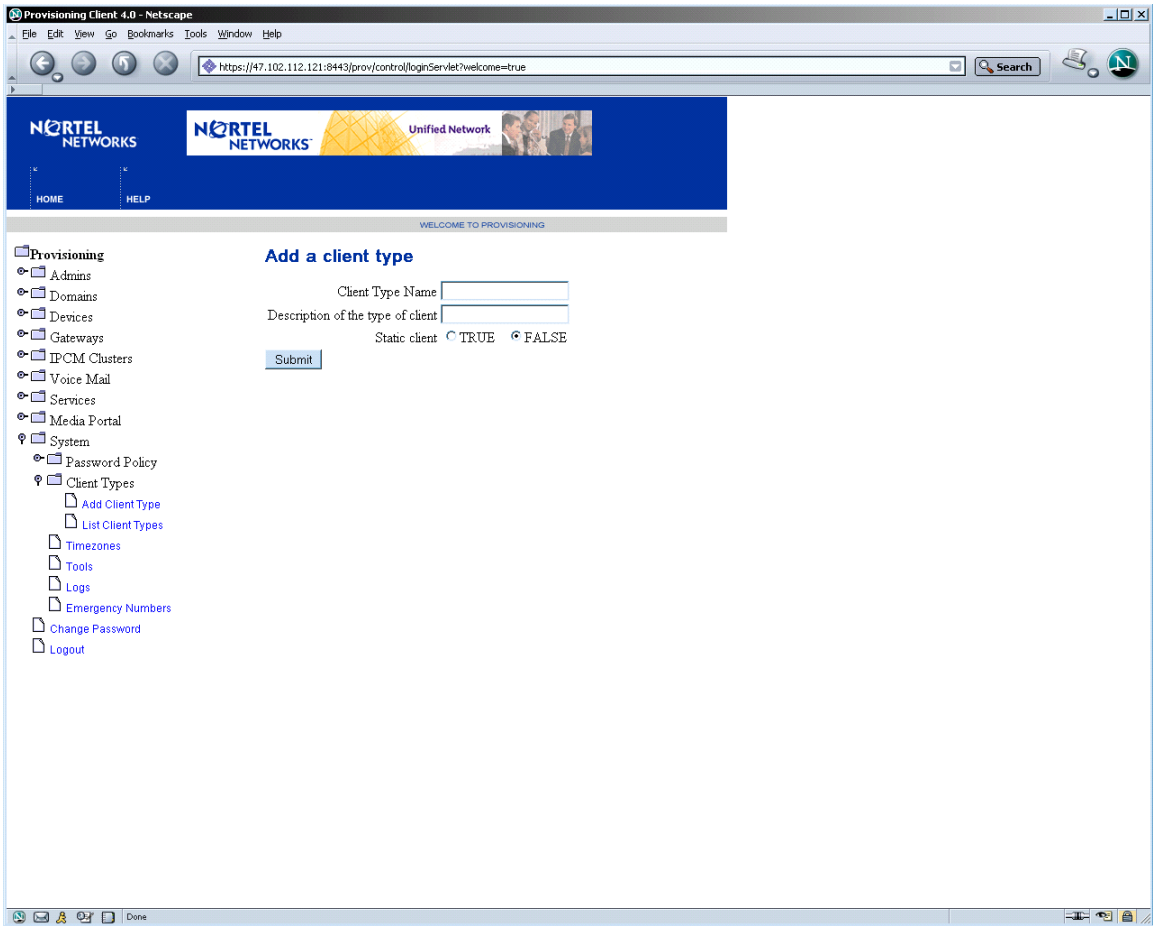

Figure 2 Client type provisioning interface

The OPI methods that can be used for Client Type provisioning are given below.

addClientType(ClientType clientType)
addClientTypes(ClientType[] clientTypes)
modifyClientType(String clientTypeName, ClientType clientType)
removeClientType(String clientType)
getClientTypeByName(String clientType):ClientType

All the client type operations need the administrator to have Full Domain Access privilege. The name of the Client Type information can be upto 60 characters long and the description can be upto 120 characters long.

The data model for the SIP Lines information and its association to the subscriber information is shown below in the figure.

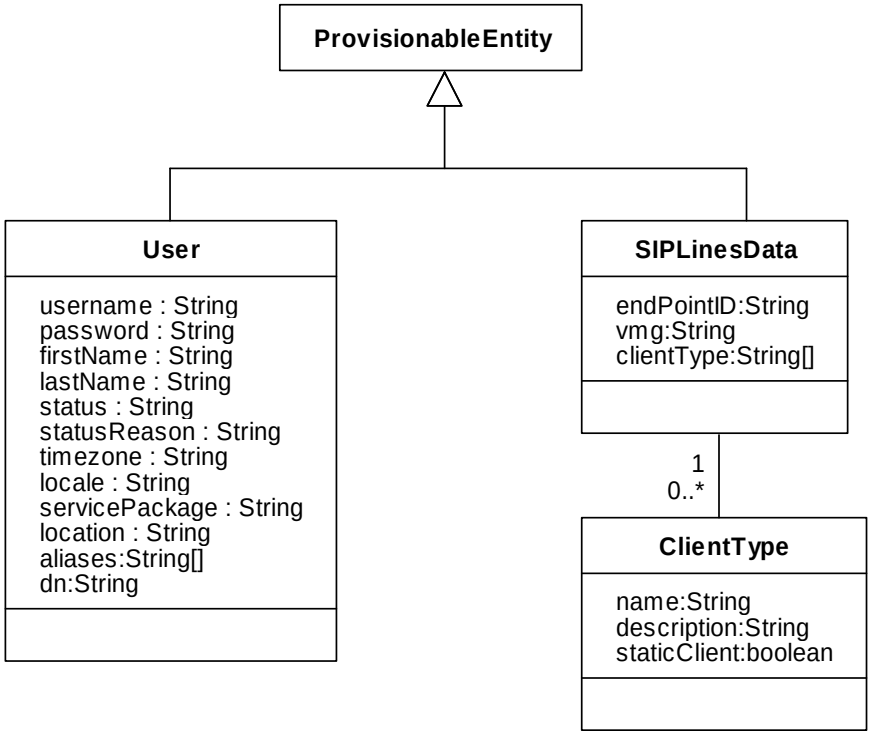

Figure 3 SIP Lines Data Model

The following table gives the required and optional field information for the above

Data	**Field Requirement**	
User	**Required**	Username,password,firstname/lastname,status, timezone, locale, service package, location
	Optional	Aliases, DN, status reason, first name/lastname (one of them)
SIPLineData	**Required**	End Point Id, VMG
	Optional	Client Type

26.4 Non SIP Line data

There is certain data that is required by OPI while adding subscribers which is not SIP Lines specific and hence can be set to a pre-defined value. Given below are three such fields and their valid values:

Field name	Possible Values
Status	ACTIVE, INACTIVE
Locale	French, English, Japanese, Simplified Chinese, Traditional Chinese, German, Spanish, Korean
Timezone	Pacific Standard Time, Mountain Standard Time, Central Standard Time, Eastern Standard Time, GMT-11:00, Hawaii Standard Time, Alaska Standard Time, GMT-04:00, Newfoundland Standard Time, GMT-03:00, Greenwich Mean Time, Central European Standard Time,G MT+02: 00, GMT+03 :00, GMT+03 :30, GMT+04 :00, GMT+05 :00, GMT+05 :30, GMT+06:00, GMT+07 :00, China Standard Time, Japan Standard Time, GMT+09 :30, GMT+10 :00, GMT+11 :00, GMT+12 :00

26.5 SESM and CS2K SS Provisioning

The SESM will be used to provision data onto the Core and CS2K SS in the SIP Lines Product. The data required on CS2K SS will be provisioned using both the Provisioning Client and also via OPI.

The following figure shows the function of the feature deliverables and its use by SESM in the product.

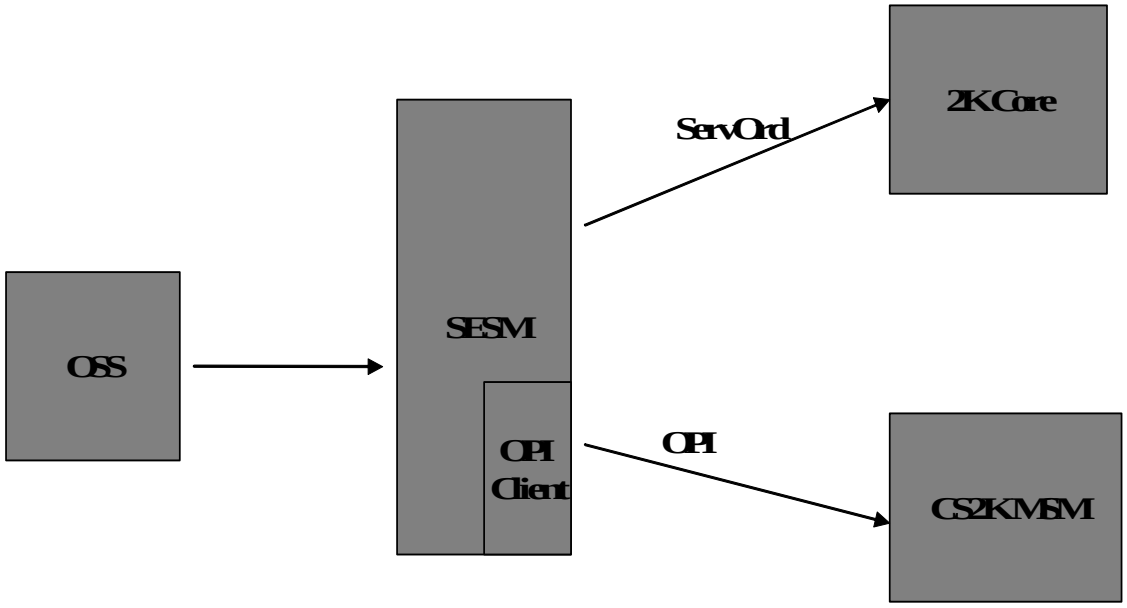

Figure 4 Flow through provisioning from and to CS2K SS in SIP lines

As mentioned above, provisioning of data for the first release of CS2K SS will involve two phases

- **Manual** - Provisioning Client will be used in this phase to provision data which would change rarely once the system is set up. This reduces the number of commands SESM has to carry out to do provisioning on CS2K SS.
- **Flow throug**h - the SESM using OPI carries out provisioning for adding subscriber and SIP Line specific information in this phase.

The existence of the following data is a pre-requisite for provisioning subscribers in CS2K SS:

- Administrator Role
- Administrator
- Root Domain
- Service Packages
- Locations
- Routability group

Figure 3 gives description of the information which can and needs to be Pre-provisioned before Flow through provisioning can take place.

The above data will be provisioned only once in CS2K SS as it will never be modified. The purpose of this data and other data that needs to be provisioned only once on CS2K SS is described below:

- **Administrator** - This is required for authentication and authorization of OPI calls during flow through provisioning from the SESM.
- **Domain** - This is where all the subscriber and end point information will be grouped under.
- **Service Package** - service packages containing the new CS2000 SIP Line service will be created. This will be assigned to all subscribers created from SESM, hence qualifying them as SIP Line subscribers.
- **Locations** - these are locations where the subscribers reside and are required for provisioning Routability groups for media portal insertion.
- **Routability Group** - This is required for the media portal insertion functionality via the zone information.

The following figure shows the data that will be manually provisioned in the CS2K SS system.

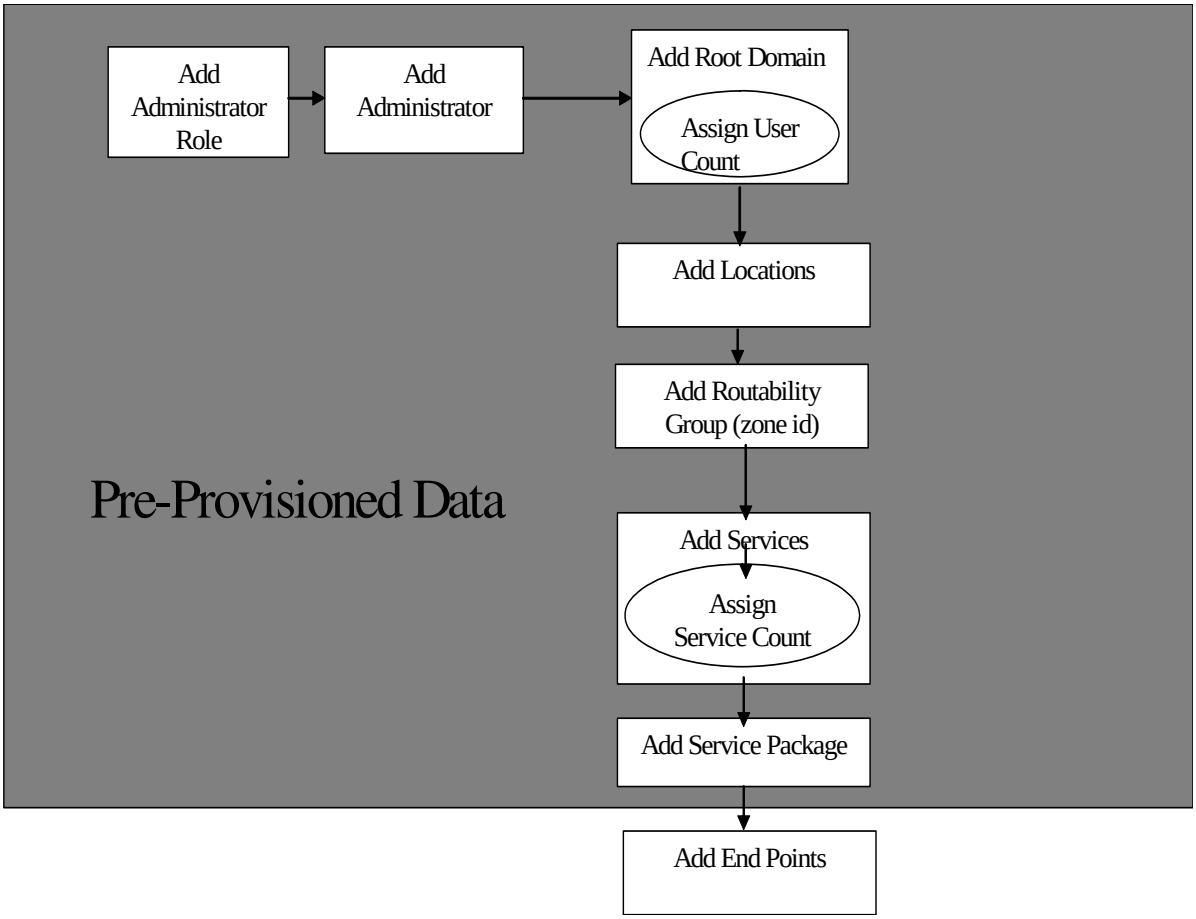

Figure 5 CS2K SS provisioning flow and pre-provisioned data information

Note:

For additional information on the provisioning client and operations please consult the Provisioning Client User Guide.

The next figure shows a sample service package with the CS2000 SIP Line service. Such a service package can be created with a mix of services which are supported on the Session Manager on CS2K SS.

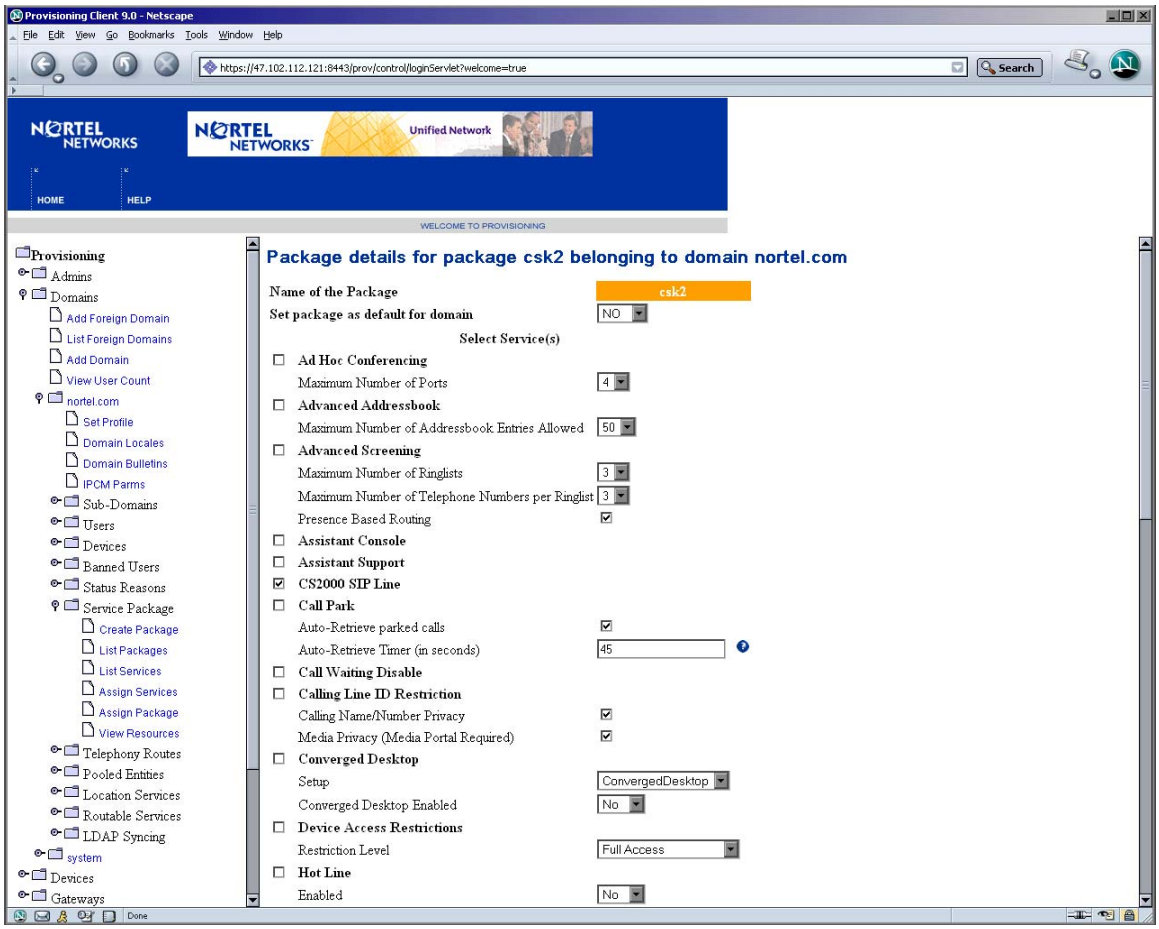

Figure 6 View of service package containing the CS2000 SIP Line service

26.6 Routability Group Information

To determine Media Portal insertion criteria by the Session Manager for services that require media portals for SIP Line calls, a new piece of data named Zone Id will be introduced as a part of the routability group information provisioned as a part of this feature. Following figure shows a view of this field

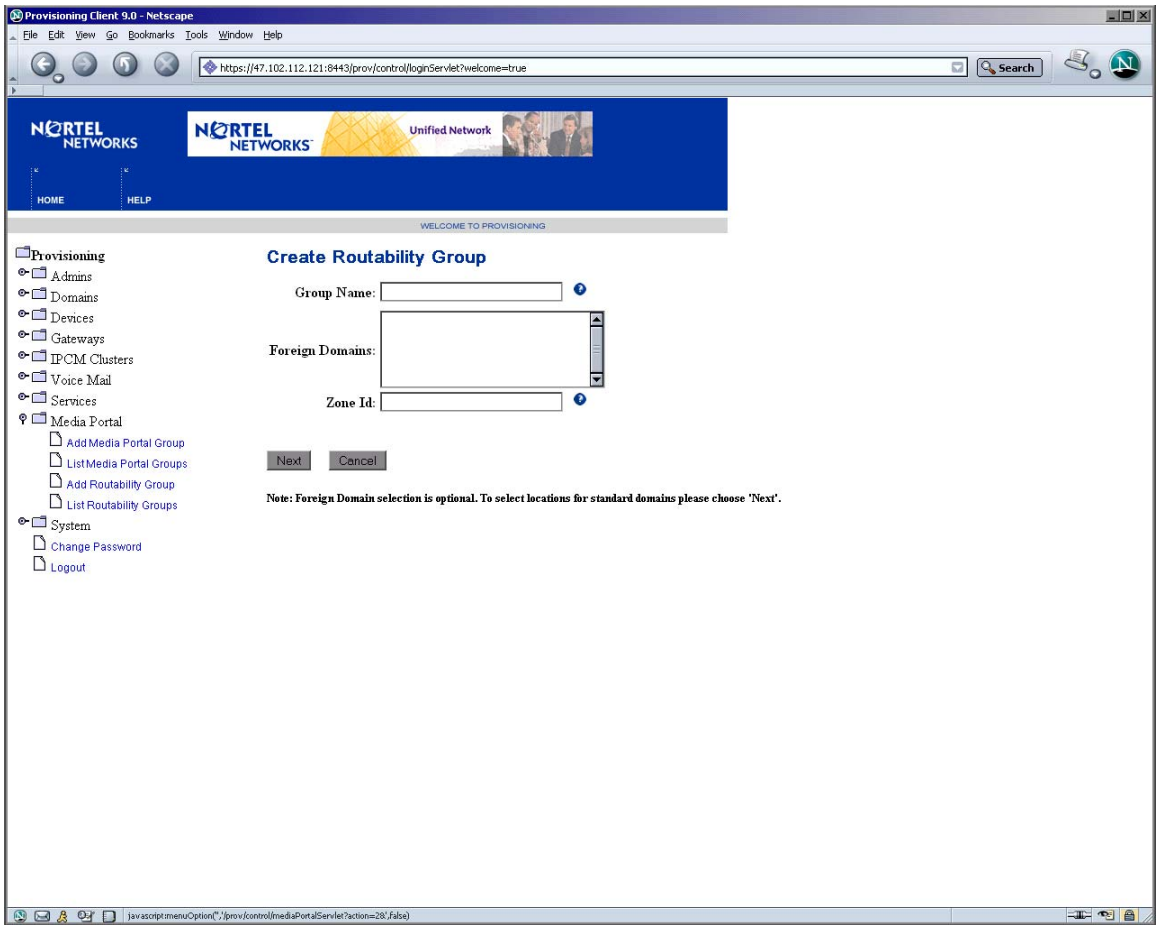

Figure 7 Zone Id information provisioning from Provisioning Client

26.7 SIP Line data provisioning using OPI

SIP Line data can be provisioned onto CS2K SS using both the Provisioning Client or OPI. The methods that are available via OPI for SIP Lines:

- Methods that will be used for user provisioning:

addUser (String domain, User user)
modifyUser (String username, User user)
removeUser (String username)
getUser (String username) : User

- new OPI methods introduced for provisioning SIP Line data

getUserByEndPoint (String endPointID):String
setSIPLineData(String userName, SIPLineData sipLineData)
getSIPLineDataByUserName(String userName):SIPLineData
removeSIPLineData (String userName)
getSIPLineData(String endPointID):SIPLineData
getSIPLineDataByDomain(String domain,int start, int stop):SIPLineData[]
getSIPLineDataByDomainByVMG(String domain, String vmg, int start, int stop):SIPLineData[]
getUserByDN(String dN):String

26.8 Hardware Requirements or Dependencies

The Provisioning Manager configuration in the SIP Lines product is as shown below. SESM will configure the Primary and secondary Provisioning Server Address and Port

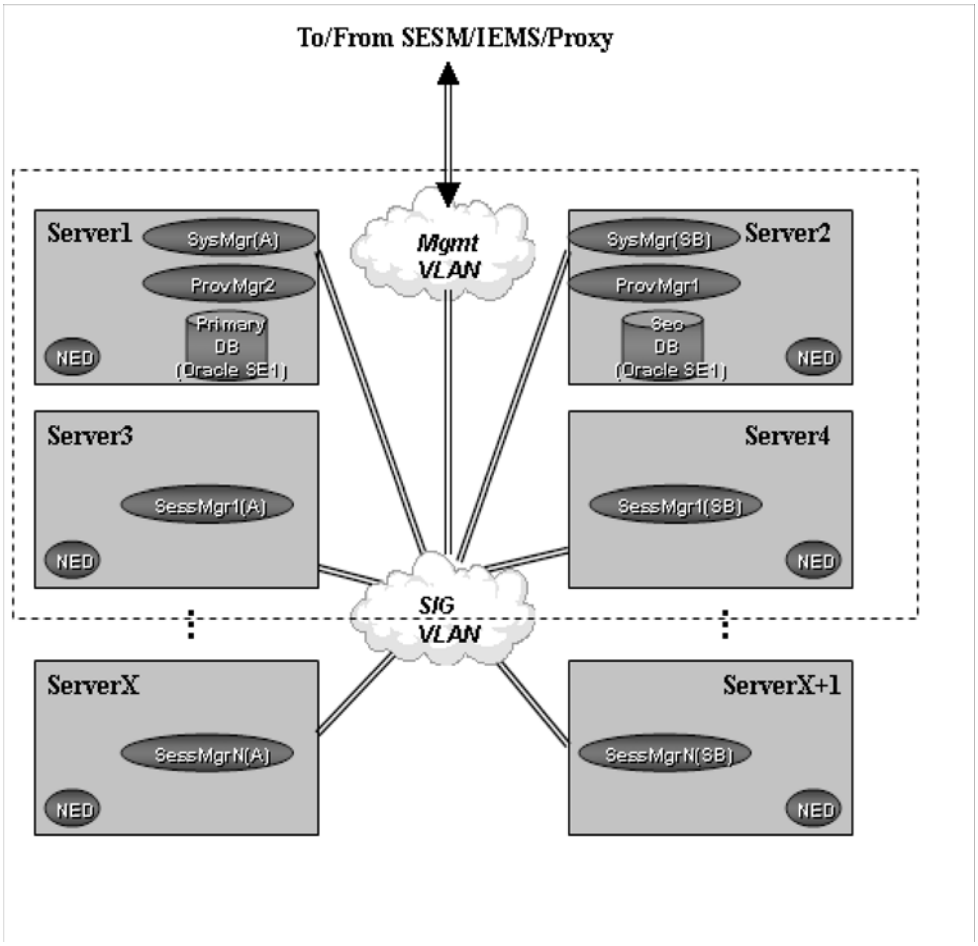

Figure 8 CS2K SS Core server hardware configuration

26.9 Software Requirements or Dependencies

The following software is required for building and using OPI on the SESM and will be delivered as a part of this feature.

- **Axis 1.1 final**: SOAP engine for OPI
- **passwdhash.jar**: contains a utility for hashing the administrator password for security reasons.
- **OPIStubs.jar**: contains the OPI client side stubs along with properties files containing error code and description mapping.
- **truststore**: for HTTPS/SSL based transactions using OPI.

The location of the software will be in the mcp_core_root and mcp_3rdparty vobs and can be accessed by the loadbuild process as needed.

26.10 CS2k SS Service Interaction

The following are services that cannot be provided from CS2K SS for a subscriber who has the CS2000 SIP Line service in the service package:

- Assistant Console
- Assistant Support
- Call Park
- Converged Desktop
- Device Access Restrictions
- Hot Line
- Music On Hold
- Net6 Support on i2004
- Wireless Client
- Voicemail
- Unified Communications
- Calling Line Id Restriction
- Call Waiting Disable
- PCClientSet Control

26.11 OPI Version and Release Information

There will be three new OPI methods introduced which will give current release and version information for OPI and MSM. The methods are:

Method Name	Purpose
getOPIVersion():String	current version of OPI
getOPISupportedVersion():String[]	List of OPI versions supported by the current release
getReleaseName():String	current release for MCP/ CS2K MSM

The information from these method calls can be used for the purpose of software upgrades based on release and OPI version that are compatible.

26.12 License key requirements and miscellaneous changes

The service CS2000 SIP Line at this time is not license keyed, meaning that the number of subscribers that can have this service is not controlled.

Also, as a part of this feature, the lengths of user name and the domain names are being increased to be 64 characters as opposed to the 60 character limit that enforced in earlier releases.

26.13 Glossary

Term	Description
OPI	Open Provisioning Interface
SESM	Succession Element and Sub-Element Manager
HTTP	Hyper Text Transfer Protocol
HTTPS	HTTP over SSL
SSL	Secure Sockets Layer
SIP	Session Initiation Protocol

27: Functional Description (FN): A00009045

27.1 Feature name and Feature ID

A00009045: CallP Checkpointing Support

27.2 Description

This feature adds the following capabilities to the CS2000 Multimedia Session Manager (MSM):

- The ability to checkpoint active calls to the standby instance of an MSM.

  For the purposes of this feature an active stable call is one that has been answered. Answering a SIP call means that the 200 OK response to the initial invite has been received or sent by the active session manager.

  Previously this information would have been lost on failover, but recreated, in part, by the long call audit and/or call clearing.

- The ability to checkpoint subscriptions to the standby instance of an MSM.

  Subscriptions refer to SIP SUBSCRIBE messages for a particular event package.Because if this checkpointing, subscription to service packages like presence , call park.. will be preserved after failover.

  Previously this information would have been lost on failover.

- The ability to checkpoint network call logs to the standby instance of an MSM.

  The call log information is preserved so that a user will be able to get a record of their calls from the Personal Agent even after a failover.

  Prior to this feature if the failover occurred before the call log was written to the DB the call log would have been lost. The database write occurs upon the completion or rejection of the call.

- Enhanced presence processing and recovery of “On the Phone” presence after failover.

  A number of enhancements have been made to presence processing. Additionally, after a failover, the newly active instance of the MSM is able to recover a user’s presence state to an “On the Phone” state if they are active in a call. Prior to this feature the user’s presence state would have been changed to “Connected” after failover.

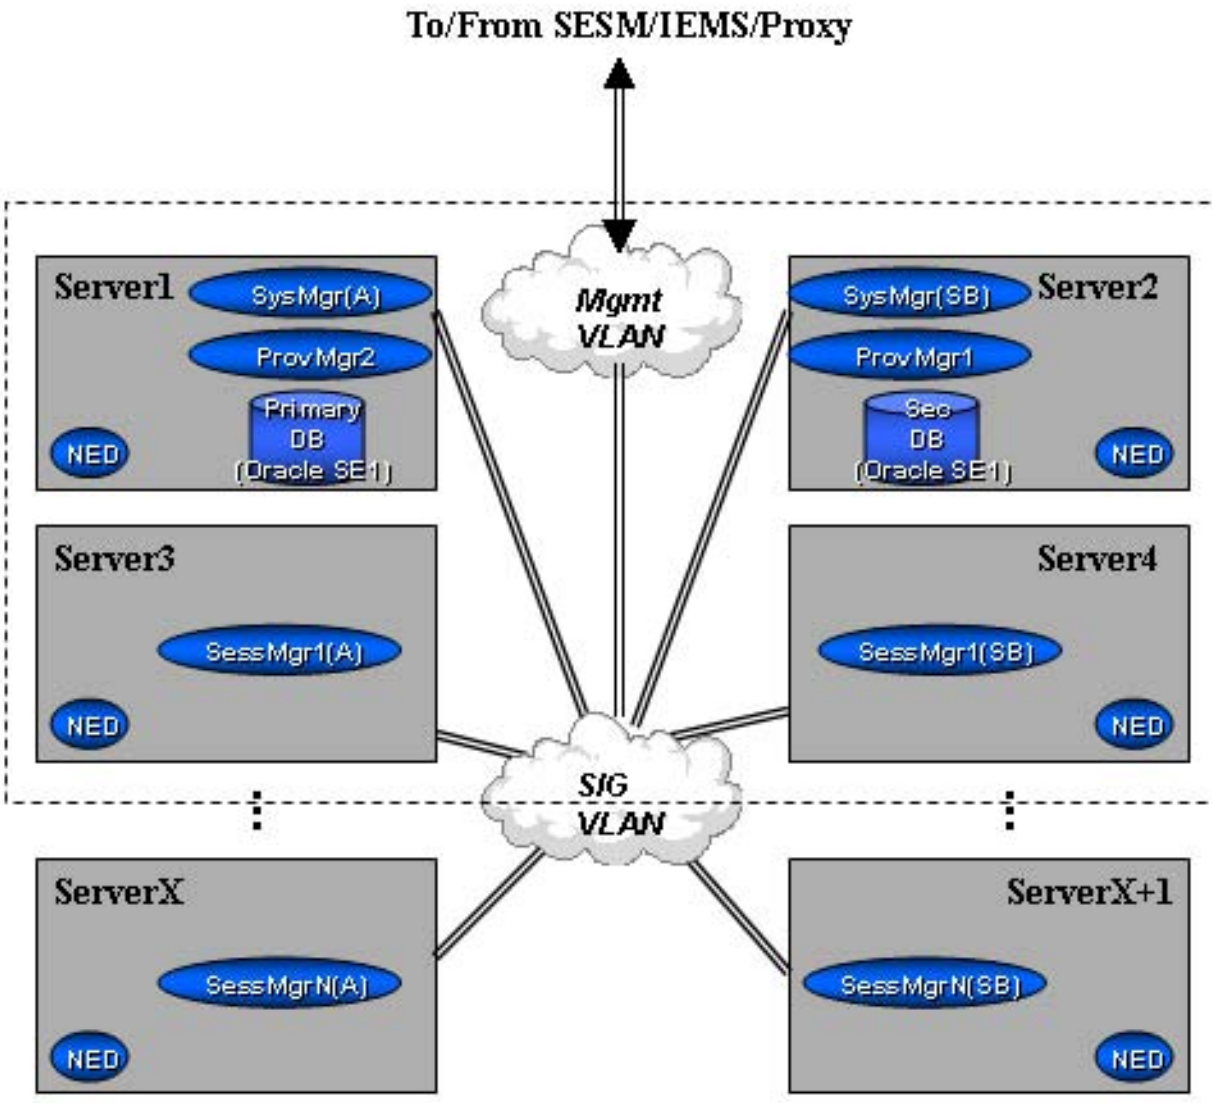
- This features adds 2 additional levels of overload to what was available in 3.0 and 4.0.

  In 3.0 and 4.0, there was only one level of overload, specified by 2 numbers, a "None" number and a "Severe" number. MCS would go into overload when the "Severe" number was exceeded. In the picture below, MCS would go into overload when the Call Queue exceeds 100. When in overload, alarms are raised, and all new sessions are blocked. Sessions that are already in progress would be allowed to continue. When the Call Queue goes below 70, the alarm is cleared, and all sessions are serviced.

27.3 Hardware Requirements or Dependencies

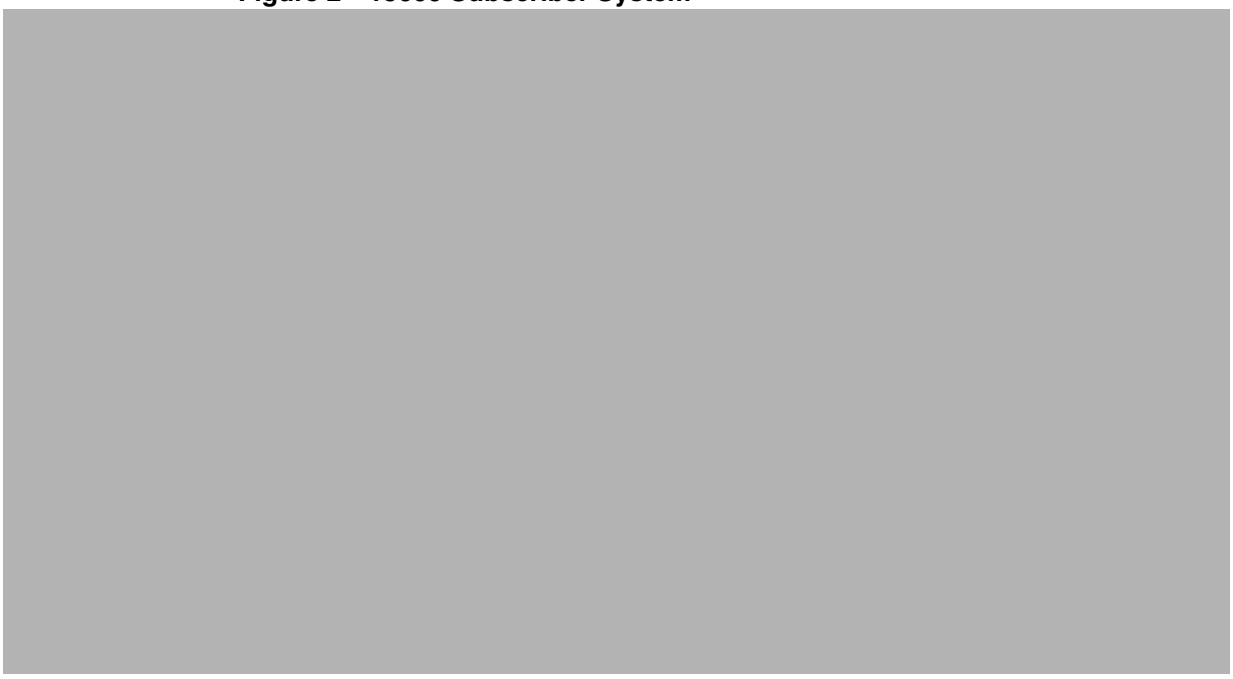
The diagram below represents the MSM configuration for 35000 subscribers. In this diagram, Server 3 and 4 represent an active/standby pair for Session manager instance 1 (SessMgr1). Server 3 is the active instance signified by the (A) and Server 4 represents the standby instance signified by (SB).

Figure 1 35000 Subscriber System



The following diagram represents the configuration for 15000 subscribers. In this diagram, SessMgr1(SB) represents the standby instance for SessMgr1(A), the active instance.

Figure 2 15000 Subscriber System



The diagrams above do not represent the only configuration possible.

27.4 Software Requirements or Dependencies

This feature is part of the MCP 9.0 release.

27.5 Limitations and restrictions

There are limitations in the processing for checkpointing. When a standby instance becomes active due to a failover there are two possible problems, both are due to the case where a Checkpoint is in process at the time the failover occurs. The newly active system can have calls active that were in the process of disconnecting and the checkpoint was not transferred before the failover occurred. In addition calls that were just setup prior to the failover will not appear on the newly active instance.This leads to inconsistent state information between the Sip Line clients, the MSM and the GWC. .

One audit goes active once the standby instance becomes the active instance to correct the inconsistencies. This audit causes the MSM to send a SIP message to all SIP Line clients the MSM thinks is active on a call to verify that they are actually on a call.

Due to the above limitations on checkpointing not all of the calls to a subscriber will be logged. Any entry in the local call log table in the process of being checkpointed at the time of the fail over will be lost. Unfortunately there is no way to mediate this loss of information.

Subscriptions have the same limitations as the call logs in that there is no way to audit them from the Session Manager. However any subscription that is lost will be refreshed by the client within one hour which is the expiration time returned by the session manager upon processing a subscription.

27.5.1 Removed Limitations and restrictions

A number of restrictions and limitations that were previously in effect have been lifted as a result of enhancements to the presence service operation.

Reporting of “On the Phone” presence is no longer limited to Nortel clients. Previously, only the Nortel IP Client Manager, Nortel Multimedia PC Client, and Nortel Multimedia Web Client were capable of reporting that they were “On the Phone” through signalling to the MSM. Now any subscriber that has an answered call going through the MSM will have their “On the Phone” presence tracked at the MSM itself. This allows third-party clients to be shown as on the phone regardless of their client’s capability set.

The MSM now detects dead clients much faster than in previous releases. This affects the scenario of a user’s client crashing or losing network connectivity and is unable to re-register with the MSM. In this case, their presence state will change to “Unavailable Offline” close to the time their last registration expires. In previous releases the interval between their last registration expiring and their presence state being updated was highly non-deterministic due to the auditing mechanism being used and system load. This mechanism has been improved to be less sensitive to system load and more timely than in previous releases.

The auditing mechanism to detect dead clients has also been applied to detecting stale clients that last reported that they are in an “Active Available” state. This is the case where a client reports that the user is actively using the PC. The MSM previously audited clients in this state by asserting that they were no longer in the active state. As a result this prompted the client to re-assert that the PC is actively being used to prevent users being shown as “Active Available” when network connectivity may have posed a challenge to accurately reporting their state. In previous releases the time period between audits was highly variable. The new mechanism reduces the variable lag time between the engineered activity auditing period and the audit being performed.

27.6 Interactions

Advanced services are not guaranteed to work after the fail over of the call. The only service guaranteed to work is the release of the call by either party in the call. Other messages will be sent a 500 service unavailable if the core is not able to process the message. Some of the services not guaranteed to work afte failover are MOH, Call Park, Boss/admin, unstable calls like consultative or blind transfers in progress , CD calls.

The presence service has been better integrated into the system overload controls. As a result, if the MSM is in a minor overload state, presence notifications will not be sent to people watching a particular user. Only the user's own self-subscriptions will be notified of presence state changes. If the MSM is in a major or severe overload state, presence notifications will not be sent to anyone. When the MSM returns to the minor overload state any postponed self-presence notifications are sent out as a background process. When the MSM is no longer in overload notifications return to normal and any postponed notifications are sent out as a background process.

Additionally, the presence service no longer processes presence events using the same processing queue as call processing. This reduces the processing time for registration requests and allows the system to handle presence processing at a different priority from call processing during overload conditions.

27.7 Operational Measurements

New OMs will be introduced with this feature.

27.7.1 Checkpoint OMs

One new OM is introduced relating to checkpointing: CheckpointedCalls.

The CheckpointedCalls OM can be used on the standby instance to monitor the number of calls that would be preserved in a case of a failover.

This OM will be reset in case of extensive connection loss between the active and standby instance, as all calls will be re-checkpointed when the connection is reestablished.

27.7.2 Presence OMs

A new OM group is introduced as part of the presence enhancements: Presence Event Report. This OM group is in addition to the OMs defined for presence in previous releases. This OM group tracks the behavior of the various presence events that are processed by the server.

For each of the rows in the report, which represent the eight presence event types: Activity, End Call, Inactive, Login, Logout, New Call, and Manual there are five columns:

- Created

  The number of events of that type that have been created in the system. This gives the operator an idea of the relative frequency of occurance for that presence event type.

  This OM is a counter register and is reset to zero after each office transfer period.

- Processed

The number of events of that type that have been processed by the presence event processor. Just because a presence event is created, does not mean that it is guaranteed to ever be processed. It may be eliminated from consideration because of an opposing presence event.

This OM is a counter register and is reset to zero after each office transfer period.

- Optimized

  The number of events of that type that have been optimized by the presence event processor. An event is optimized when it an opposing presence event is processed that nullifies the presence event change that would have taken place. For instance, if a new call event is processed, and the presence event processor sees that there is an opposing end call event in the queue or parked, there is no further point in processing either event, they cancel each other out.

  This OM is a counter register and is reset to zero after each office transfer period.

- Queued

  The number of events that are currently in the presence event processor queue waiting to be processed.

  This OM is a usage register. It increments and decrements according to the length of the processing queue and is unaffected by the office transfer.

- Parked

  The number of events that have been initially processed, but must wait for the presence guard timer to expire before being processed. These events are “parked” waiting for the guard timer to expire before being applied. They are frequently candidates for optimization.

  This OM is a usage register. It increments and decrements according to the length of the processing queue and is unaffected by the office transfer.

In addition to the new OM group, the following OMs are added to the existing “Presence” OM group:

- throttleNotifySelfOnly

  This OM is pegged every time the system does not send out a notifications to non-self subscriptions because of a presence state change during minor overload. This is pegged once for the entire state change, and does not reflect the actual number of notify messages that were not sent out.

This OM is a counter register and is reset to zero after each office transfer period.

- throttleNotifyAll

  This OM is pegged every time the system does not send out any notifications, including self-subscriptions because of a presence state change during major or severe overload. This is pegged once for the entire state change, and does not reflect the actual number of notify messages that were not sent out.

  This OM is a counter register and is reset to zero after each office transfer period.

27.8 System Manager Changes

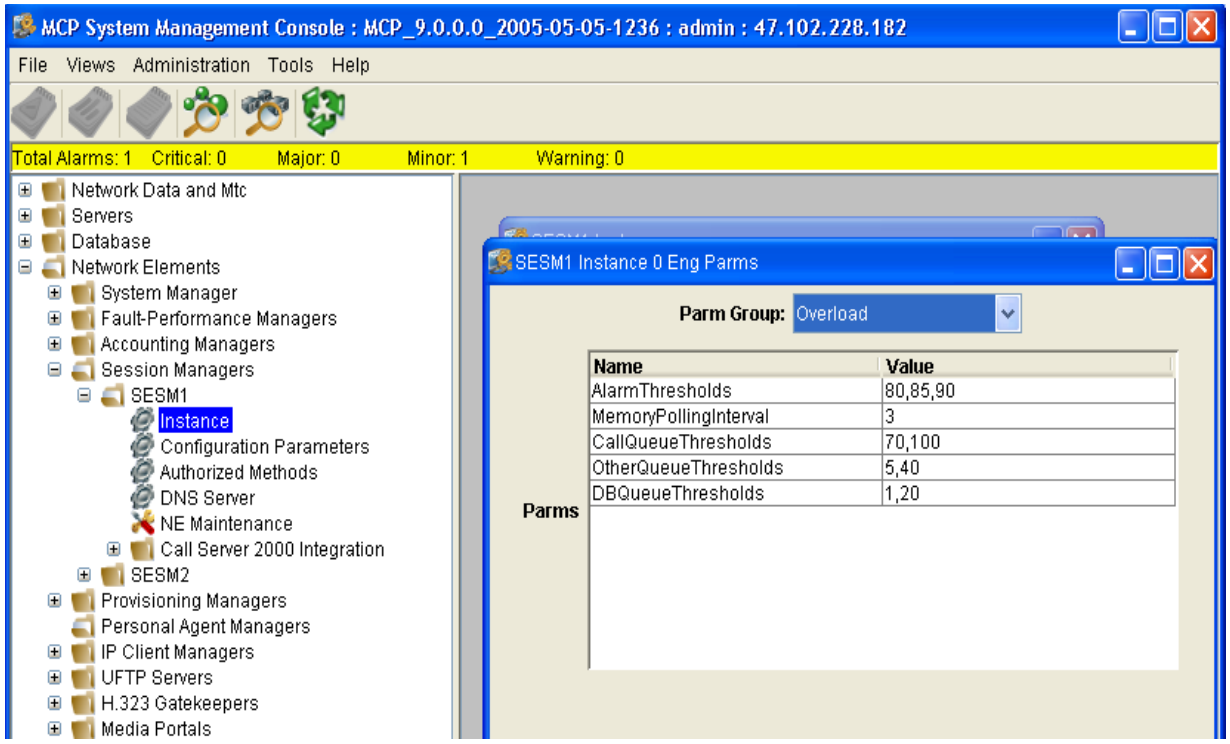
Instead of just having the Severe overload condition, there are 2 other overload conditions. They are:

- Minor -- presence notifications except to self and admins won't be generated.
- Major -- Same as in Minor, additionally, IM will be blocked.
- Severe -- Everything except in-session messages will be blocked.

To specify the additional levels, instead of just having the "None" and "Severe" numbers, the format is to accept 4 numbers: "None", "Minor", "Major", and "Severe".

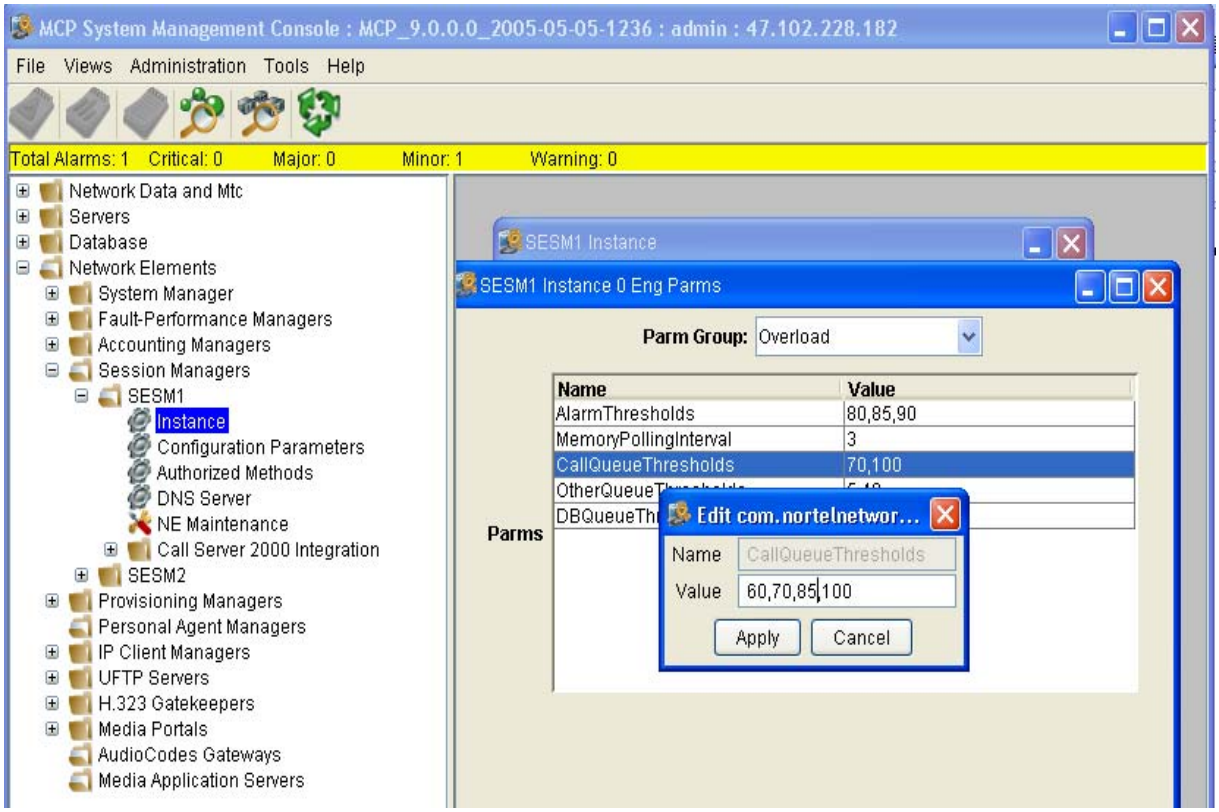
If only 2 levels are specified, such as after an upgrade, then the same behavior as in 3.0 and 4.0 is provided (see Figure 14, “Existing Overload Engineering Parameters,” on page 242).

Figure 14: Existing Overload Engineering Parameters



When four numbers are provided, the increased overload granularity is enabled. In the example below (Figure 15, “New Overload Engineering Parameters,” on page 243) if the Call Queue exceeds the Minor number (70), and stays at that level for a few seconds, MCS will stop generating presence notifications. If the Call Queue exceeds the Major number (85), then Instant Messages will be blocked. If the Call Queue exceeds the "Severe" number, then all new sessions will be blocked. For any of the overload conditions, the same alarm is raised, but different severities are assigned to those alarms.

Figure 15: New Overload Engineering Parameters



27.9 Glossary

Term	Description
Info Ping	A SIP INFO message sent without a message body. The proper response is a 200 Ok if the INFO is within a call and a 481 if outside of a call. Defined in RFC 2976
MSM	Multimedia session Manager
SIP	Session Initiation Protocol

28: Functional Description (FN): A00009078

28.1 Feature name and Feature ID

A00009078: ICM Dual CTI.

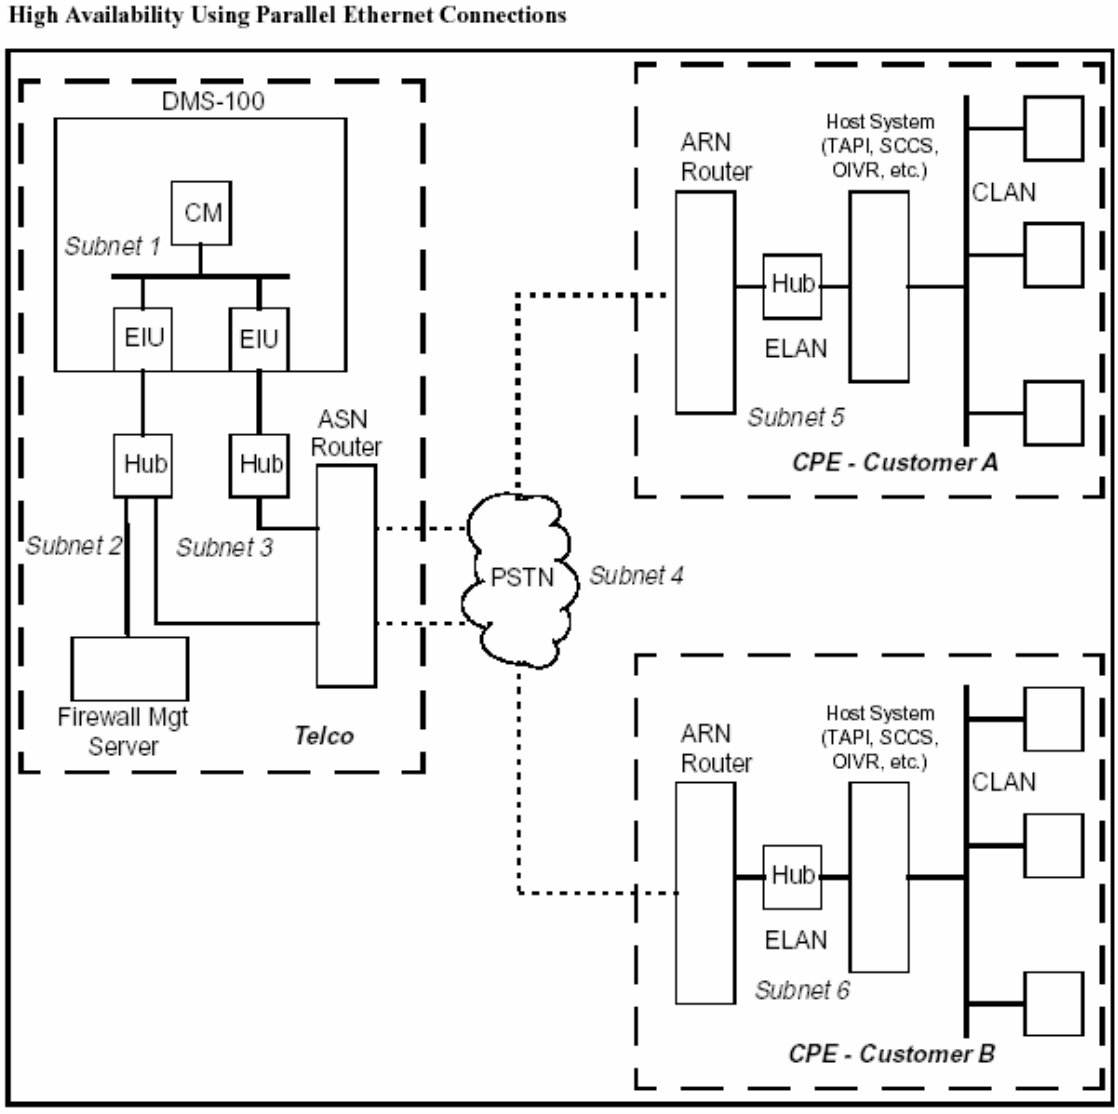
28.2 Description

Currently ICM only has one TCP/IP link per linkset. This feature will allow two TCP/IP connections to exist in one SCAI session. The second link will mirror the first link by broadcasting all switch to Host messages except the continuity test messages to both the TCP links. The switch would only expect a response where necessary from the Host through one of the TCP links within the linkset.

This feature does not need more than one EIU to function. The two TCP/IP links within the linkset can connect to a single EIU. It is the customer's responsibility to provide a reliable and properly configured network. For reliablity, Nortel recommends that the EIU's be configured on separate subnets and be configured in interface mode such that one TCP/IP link within the linkset connects to one EIU within one subnetwork and the other TCP/IP link within the linkset connects to the EIU in the other subnetwork. When EIU's are configured in the interface mode, the Host must use the IP address of the EIUs to connect to DMS-100.

For CS2Kc customers the connection will be made using one IP address for both ICM links within a linkset

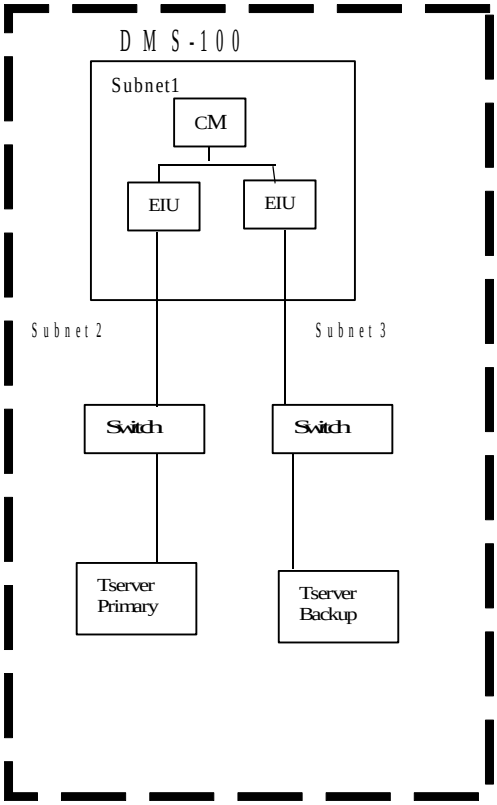
Figure 1 : High Availability Using Parallel Ethernet Connections



In the figure 1 above, the EIUs may be connected to either Eithernet hubs or switches. Hubs are blocking devices which will drop a packet when thereis a packet collision. Switches are non-blocking and should be utilised when there is a possibility of collisions(eg: When other Ehternet devices are connected).

Another simplified configuration can be used if the Tserver and the DMS-100 are co-located, meaning they are not far apart. The allowed distance between the Tserver and DMS-100 for this configuration depends on the hardware specification for each unit used.

Figure 2 Simplified Configuration for High Availability



Please refer to the CN section of this document for details on the datafill needed for this feature to work

28.2.1 Continuity Testing

The continuity test for the TCP links within a linkset will be enhanced to work as it does for multiple X.25 links within a linkset.

The continuity test message will be sent in a round robbin fashion to both links from the DMS. The DMS will wait for the response up to the datafilled response time before it will send it to the next link. DMS will expect a response from the corresponding link on the application. If the DMS does not receive the response to this test within the response time, the test would have failed for that link after the number of attempts has been exhausted.

If both links fail the test, then the session will be either taken down or not according to how the Terminet parm is datafilled per linkset. When the DMS detects that one of the link has failed, the broadcasting of messages to both links will stop and only the live link will be used to send the ICM messages.

When the continuity test is initiated from the Tservers, the DMS will respond to each of the continuity messages it receives by broadcasting the response to both links.

28.2.2 SOC

This feature uses Software Optionality Control (SOC). The SOC order code is ICM00081. Please refer to the CN section of this document for further details on SOC. This feature will not function if the SOC is not turned on.

28.2.3 OMs & Logs

Changes will be made to the OMs for TCP/IP linksets. The OM will now show the existing registers for each TCP/IP link as a separate tuple.
Example:

Existing tuple

16 TCP_AA

0 0 0 0

Will now appear as

16 TCP_AA **0**

0 0 0 0

If there a two links within a linkset it will appear as below:

21 TCP_BB **0**

0 0 0 0

23 TCP_BB **1**

0 0 0 0

The number next to the linkset name represents the link number within the linkset

No new logs or changes to the existing logs are needed for this feature.

28.2.4 Tools

SCIDBG13: This tools is used to debug the SCAI application. Changes will be made to the following commands in the tool to accommodate the second TCP/IP link within the TCP linkset.

- PRINT

-CLEAR
- RESET

SCAITCP: This is a MAP level tool to monitor the ICM application. The following commands of the tool will be enhanced to accommodate the addition of another TCP/IP link within the TCP linkset.

Query Linkset
Clear SessionID

Clear Linkset

Clear Invokes

Clear Transport

SCAItest Sanity.

28.3 Hardware Requirements or Dependencies

The TCP/IP transport uses the existing TLI interface to provide connectivity between the DMS-100 and a business computer. It also makes use of Local Area Network (LAN) and an internet router. The DMS is provided with LAN connectivity by an Ethernet Interface Unit (EIU). The EIU acts as an router between the DMS-100 and an internet router. If there are more than one link per linkset, the EIUs need to be in an interface mode for reliability. Messages originated from the business computer are routed through internet and finally terminates on a router which is connected to Ethernet LAN and are sent to the EIU which forwards the messages to the destination node on the DMS.

For CS2Kc, a primary and a backup 3PC card will be used to make the TCP/IP connections. Only a single IP address will be available for the Host to connect to the CS2Kc.

28.4 Software Requirements or Dependencies

The feature enhances already existing ICM software to handle the following areas:

Table Control mechanism to support additional TCP/IP link within a linkset.

Auditing for two TCP/IP link per linkset.

OMs and Logs changes for redundant TCP/IPlink per linkset.

SCAI tools, SCIDBG13 (CI tool) and SCAITEST (MAP level tool).

This feature also adds new code to support SOC for this feature.

28.5 Limitations and restrictions

Maximum number of TCP/IP connections are 96. No more than 96 service nodes and switches could be connected to a single switch. This is assuming no other applications are using TCP/IP connections from the CM. Therefore the maximum linksets available if all of the TCP/IP linksets are provisioned with two TCP/IP links will be 48.

CS2K will only provide one IP address for the Host to connect to it. Both links will use the same IP address to connect to the CS2K.

28.6 Interactions

This feature will interact with the existing SCAI X.25 transport due to enhancements made in the existing X.25 Table Control mechanism to support two TCP/IP links per linkset.

It will also interact with the current TCP/IP transport implementation that supports a single TCP/IP link per linkset.

29: Functional Description (FN) A00009085

29.1 Feature name and Feature ID

A00009085: ACD & ICM Capacity Expansion

29.2 Description

Currently, the following limitations apply to the ACD and ICM capacities in a SL-100 or DMS-100 switch:

1. A maximum of 30,000 ACD Agents can be provisioned.
2. A maximum of 1,024 ACD Groups can be provisioned.
3. A maximum of 256 ACD Subgroups can be defined for a given ACD Group.
4. A maximum of 256 Supervisors can be defined for a given ACD Group.
5. A maximum of 1,024 ACD Agents can be associated with a given ACD Group.
6. A maximum of 511 calls can be simultaneously queued for a given ACD Group.
7. A maximum of 511 incoming overflowed calls can be simultaneously queued for a given ACD Group.
8. A maximum of 100 DNs can be associated with a given ICM Session.

This feature will expand these capacities to the following limits:

1. The maximum number of ACD Agents per switch will be increased to 99,999.
2. The maximum number of ACD Groups per switch will be increased to 5,000.
3. The maximum number of ACD Subgroups per Group will be increased to 2,500.
4. The maximum number of Supervisors per ACD Group will be increased to 2,500.
5. The maximum number of ACD Agents per Group will be increased to 10,000.
6. The maximum number of simultaneously queued calls per ACD group will be increased to 8,192.
7. The maximum number of simultaneously queued incoming overflowed calls per ACD Group will be increased to 8,192.
8. The maximum number of DNs that can be associated with a given ICM Session will be increased to 250.

29.3 Hardware Requirements or Dependencies

N/A

29.4 Software Requirements or Dependencies

This feature enhances the existing ACD and ICM software to provide the increased capacities. The following areas will be impacted by this feature:

- Table ACDGRP will be expanded to allow the provisioning of up to 5,000 ACD Groups per switch.
- Table ACDSGRP will be enhanced to allow provisioning of up to 2,500 ACD Subgroups per Group.
- Table ACDLOGIN will be expanded to hold a maximum of 99,999 tuples.
- Table ACDENLOG will be expanded to hold a maximum of 99,999 tuples per partition.
- SERVORD commands (NEW, ADO, NEWACD, CHF, etc.) will be enhanced to support position IDs up to 99999.
- A new ACDMIS protocol version (BCS57) will be defined to support the expanded login and position IDs.
- The ACDMIS load management/remote load management code will be enhanced to support the expanded login and position IDs.
- ACD and ICM Call Processing code will be enhanced to support the expanded login and position IDs.
- ACDDEBUG and ACDSHOW tools will be enhanced to support the expanded login and position IDs.
- Enhancements will be made to the ACD00101 SOC code to support the increase in the maximum number of ACD Agents per switch.

This feature also adds new code to provide the following SOCs to manage the various capacity increases:

- ACD00104 - to control the maximum number of ACD Groups per switch. This SOC will also control the maximum number of ACD Subgroups and Supervisors per Group.
- ACD00105 - to control the maximum number of ACD Agents per Group.
- ACD00106 - to control the maximum number of incoming and incoming overflowed calls per ACD Group.
- ICM00082 - to control the maximum number of DNs that can be associated per ICM Session.

29.5 Limitations and restrictions

It must be noted that all of the capacities described in this document can not be taken to the maximum simultaneously in a given switch.

29.6 Interactions

No changes are made to the existing interactions by this feature.

30: Functional Description (FN) A00009091

30.1 Feature name and Feature ID

SN09: A00009091 - Equal Access (EA) LPIC Privilege Routing

30.2 Introduction

This feature introduces two new capabilities to the SN09 release:

1. The capability to partition a DMS100/CS2000 into multiple Virtual End Offices (VEO) using a new translation attribute intended for public translation capabilities.
2. New LPIC Privilege Routing capability, which is the first functionality to make use of the new VEO partitioning.

Future releases may provide additional enhancements of public translation to utilize the new VEO partitioning capability.

30.3 Description

Two new capabilities are introduced by this feature. Please refer to the following sections for additional information:

- Section 30.3.1 “New Virtual End Office Capability” on page 253
- Section 30.3.2 “New LPIC Privilege Routing Functionality” on page 256

30.3.1 New Virtual End Office Capability

With this feature, a DMS100/CS2000 can be partitioned into two or more virtual end-offices. This provides a logical partitioning of originating agents on one DMS100/CS2000 into multiple VEOs.

Table VEONAME is introduced by this feature to provide an inventory of the VEO names. A VEO name is associated with valid “originating EO agent types” through new provisioning option VEONAME, in table XLAPLAN or table CXGRP.

The originating EO agent types that are supported by this activity include:

- All line types (e.g., RES, POTS, IBN, console) in the SN09 release except Line Class Codes (LCC) of *EOW* (Enhanced Outwats) and *ETW* (Enhanced Two-Way WATS).
- IBN trunks
- PRI trunks
- PX trunks (with exception of EWATS agents)

- virtual lines - RCF, RCFEA
- VFGs

VEO functionality is completely optional via provisioning in tables XLAPLAN and CXGRP.

For additional information please refer to the following sections:

- Section 30.3.1.1 “New Table VEONAME” on page 254
- Section 30.3.1.2 “New option VEONAME, Table XLAPLAN” on page 255
- Section 30.3.1.3 “New option VEONAME, Table CXGRP” on page 255

30.3.1.1 New Table VEONAME

New table VEONAME contains the list of VEO names. Each VEO name represents a virtual end office that is partitioned on the DMS100/CS2000.

Table VEONAME can provision up to a maximum of 999 VEO names, with an additional VEO name reserved as nil VEO name (NILV).

Refer to Table 1 for a Description of the key field of table VEONAME. The key field VEONAME is a string of up to 16 characters and is mapped to a string range.

Table 1 New Table VEONAME

Key	Values	Comments
Key: VEONAME	CHAR_VECTOR (16)	The table key specifies the Virtual End Office Name.

Following is a provisioning example for new table VEONAME.

Figure 1 Example of Table VEONAME

Table VEONAME:

```
VEONAME
--------------------
NILV
ENDOFFICE1
ENDOFFICE2
```

30.3.1.2 New option VEONAME, Table XLAPLAN

Table XLAPLAN provides an association between End Office (EO) originating agents and their translation types.

New option VEONAME is added to table XLAPLAN. Option VEONAME provides an association between the originating line/trunk agent and the Virtual End Office (VEO). This provides the flexibility to partition the DMS100/CS2000 into multiple virtual end offices.

Example datafill for table XLAPLAN is as follows.

Figure 2 Example datafill of Table XLAPLAN

```
Table XLAPLAN:

XLAPIDX  SCRNCLHSTS  PRTNMZEROMPOS RESINF  OPTIONS  ADMINF
-------------------------------------------------------------------------------------------
613_P621_0  FR01  613   P621  TSPS Y  RESGRP 0 2 VEONAME ENDOFFICE1   $
```

30.3.1.3 New option VEONAME, Table CXGRP

Table CXGRP (Customer Group Options) is required in local or combined local/toll switches to define the options associated with a PX digital trunk. The PX trunk agent tuple in table TRKGRP contains the field for PX Customer Group which is the index into table CXGRP.

New option VEONAME is added to table CXGRP. Option VEONAME provides an association between the originating PX trunk agent and the Virtual End Office (VEO). This provides the flexibility to partition the DMS100/CS2000 into multiple virtual end offices.

Note: Table CXGRP does not show up in Traver. See Figure 12.

Example datafill for table CXGRP is as follows:

Figure 3 Example datafill of Table CXGRP

```
Table CXGRP:

CUSTKEY SPB CTD FCTDNTER FCTDNTRA FCTDINT EWATS EWATSI
PXOPTION
-----------------------------------------------------------------------------------------------
50 N N N N N N N (LPIC CAR1 Y) ( VEONAME ENDOFFICE2 ) $
```

30.3.2 New LPIC Privilege Routing Functionality

The second capability introduced by this activity is LPIC Privilege Routing. When an LPIC is assigned to an originator, the DMS100/CS2000's behavior prior to this feature was to route all intraLATA toll calls to the LPIC. This feature introduces the ability to provision intraLATA toll NPANXX codes as exceptions to LPIC handling. Instead of routing to the LPIC, these NPANXX codes will be handled by the LEC.

A new table LPICPXLA is introduced to allow NPANXX LPIC privilege codes to be provisioned on a per VEO basis. New SOC EQA00032 is also introduced as a call processing and Traver control for the LPIC Privilege Routing capability.

For additional information please refer to the following sections:

- Section 30.3.2.1 "New Table LPICPXLA" on page 256
- Section 30.3.2.2 "New SOC EQA00032" on page 258
- Section 30.3.2.3 "Call Processing Enhancements" on page 259
- Section 30.3.2.4 "Traver Enhancements" on page 262
- Section 30.3.2.5 "Service Interactions with LPIC Privilege Routing" on page 271

30.3.2.1 New Table LPICPXLA

New table LPICPXLA is implemented to provision a list of NPANXX codes to be excluded from LPIC routing on per VEO basis. This table will be implemented using digilators for storing the NPNXX Codes and will be using 1 digilator pool of 32k 1-digits blocks.

Table LPICPXLA is accessed during call processing for an originating agent when the following is provisioned:

- VEONAME is provisioned in table VEONAME,

- table XLAPLAN entry for the originating agent's pretranslator has option VEONAME assigned (or for a PX trunk originator, option VEONAME is assigned in table CXGRP),
- and SOC EQA00032 'VEO LPIC Privilege' is turned ON.

Refer to Table 2 for a Description of table LPICPXLA. The key field PRIVCODE is made up of two parts:

- VEONM: Virtual End Office Name provisioned in Table VEONAME

- DIGITS: up to six NPANXX digits from the dialled number.

Table control enforcements:

— a VEONAME tuple can not be provisioned as nil VEO name (NILV),

— upto six-digit NPANXX codes are allowed to be provisioned as privilege codes in Table LPICPXLA.

Table 2 New Table LPICPXLA

Key	Values	Comments
Key 1: VEONM	VEO_NAME (String range 0 to 999)	Key 1 specifies the originating subscriber's Virtual End Office Name.
Key 2: DIGITS	DIGIT_REGISTER	Key 2 specifies NPANXX codes provisioned for each VEONAME.

Following is a provisioning example for new table LPICPXLA.

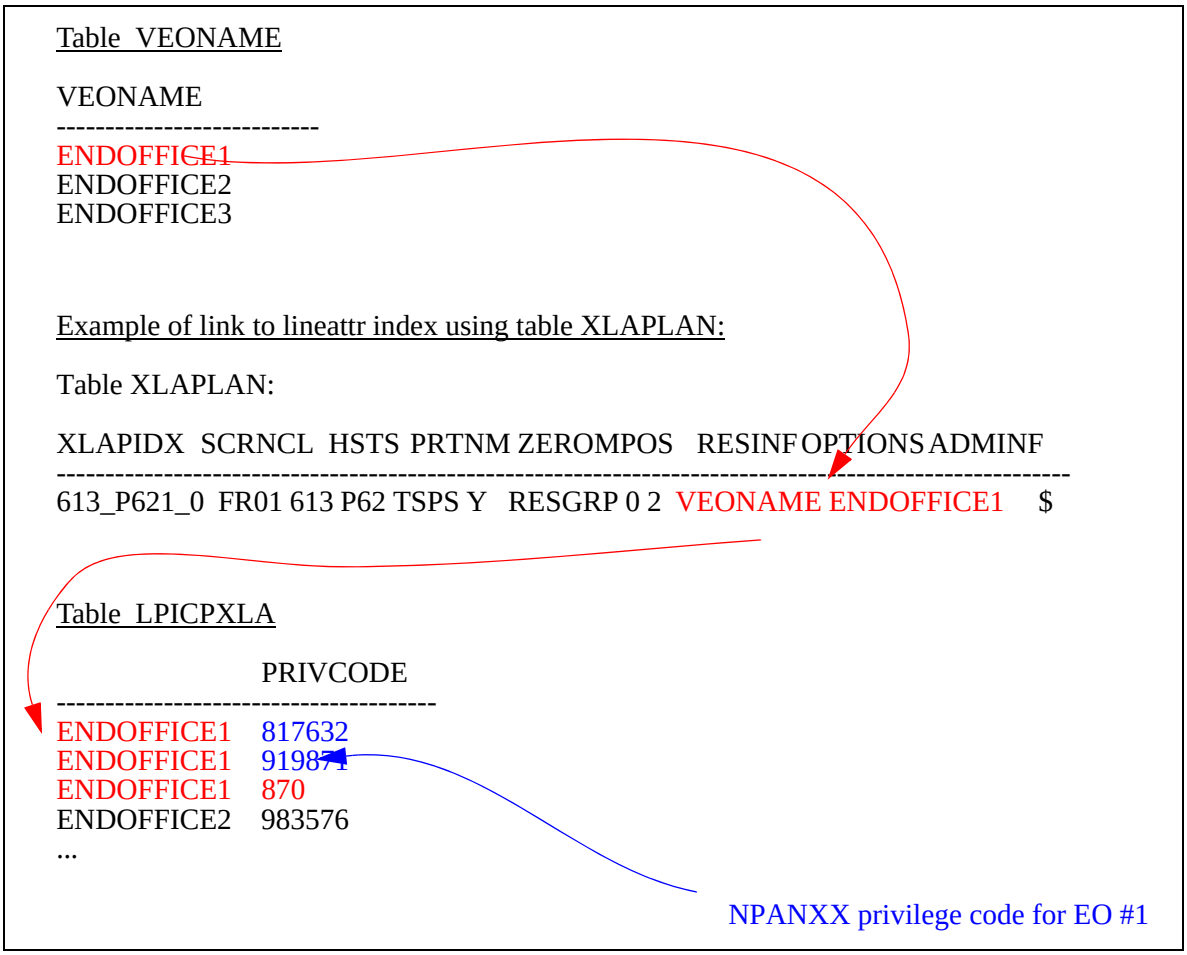
Figure 4 Example of Table LPICPXLA

Table LPICPXLA:

```
                PRIVCODE
----------------------------------
ENDOFFICE1      919484
ENDOFFICE2      212
```

The following figure illustrates the association between tables VEONAME, XLAPLAN, and LPICPXLA. For additional information please refer to Section 30.3.2.3 "Call Processing Enhancements" on page 259.

Figure 5 LPIC Exception Routing Datafill



30.3.2.2 New SOC EQA00032

A new state controlled SOC, EQA00032 ‘VEO LPIC Privilege’ is added by this activity. The SOC will have two states: IDLE, ON. This SOC, along with the assignment of the VEONAME option for the originating agent, controls both the call processing and Traver enhancements provided by this activity.

When SOC is in IDLE state:

- Table VEONAME can be provisioned.
- The new option VEONAME can be provisioned in table XLAPLAN and table CXGRP.
- The new option VEONAME can be provisioned in table LPICPXLA with NPANXX privilege codes.
- Table LPICPXLA is not accessed by call processing or by Traver. For further detail, refer to Section 30.3.2.3 “Call Processing

Enhancements” on page 259, and Section 30.3.2.4 “Traver Enhancements” on page 262.

When SOC is in ON state:

— Call processing and Traver will both access new table LPICPXLA if the originating agent has VEONAME assigned.

The functional group ordering code for EQA00032 is EQA00001, EQA Local.

All service interactions with SOC EQA00032, including EQA00024 ‘Override LPIC Priv’ feature, are described in Section 30.3.2.5 “Service Interactions with LPIC Privilege Routing” on page 271.

30.3.2.3 Call Processing Enhancements

The DMS100/CS2000 call processing software is enhanced to support the LPIC Privilege Routing capability. Figures 6 and 7 provide flowcharts of the enhanced call processing behavior. This feature is active only when SOC EQA000032 is set to ON and the originator has a VEONAME assigned.

Supplemental Information for the flowcharts.

1. Deriving LATA status of the call - There are no changes to the method of deriving the LATA status from Table LATAXLA. Existing behavior is to index Table LATAXLA with the originator’s LATA name and the dialed number. If the dialed number is a 7 digit dialplan then originator’s LATA name and the SERVING NPA[1](SNPA) plus the dialed number are used for the index into Table LATAXLA. Special considerations are required for some services. Please refer to Section 30.3.2.5 “Service Interactions with LPIC Privilege Routing” on page 271, for more details.
2. Performing Look-up in Table LPICPXLA - The index for the new Table LPICPXLA is the originator’s VEONAME and the terminating number. If the terminating number does not contain enough digits to determine if a match is found then more digits must be collected. As with Table LATAXLA, if the dialed number is a 7 digit dialplan then originator’s VEONAME and the SNPA with the dialed digits are used for the index into Table LPICPXLA. Special considerations are required for some services. Please refer to Section 30.3.2.5 “Service Interactions with LPIC Privilege Routing” on page 271 for more details.

[1]Serving NPA is the NPA of the originating party.

Figure 6 Equal Access Translations

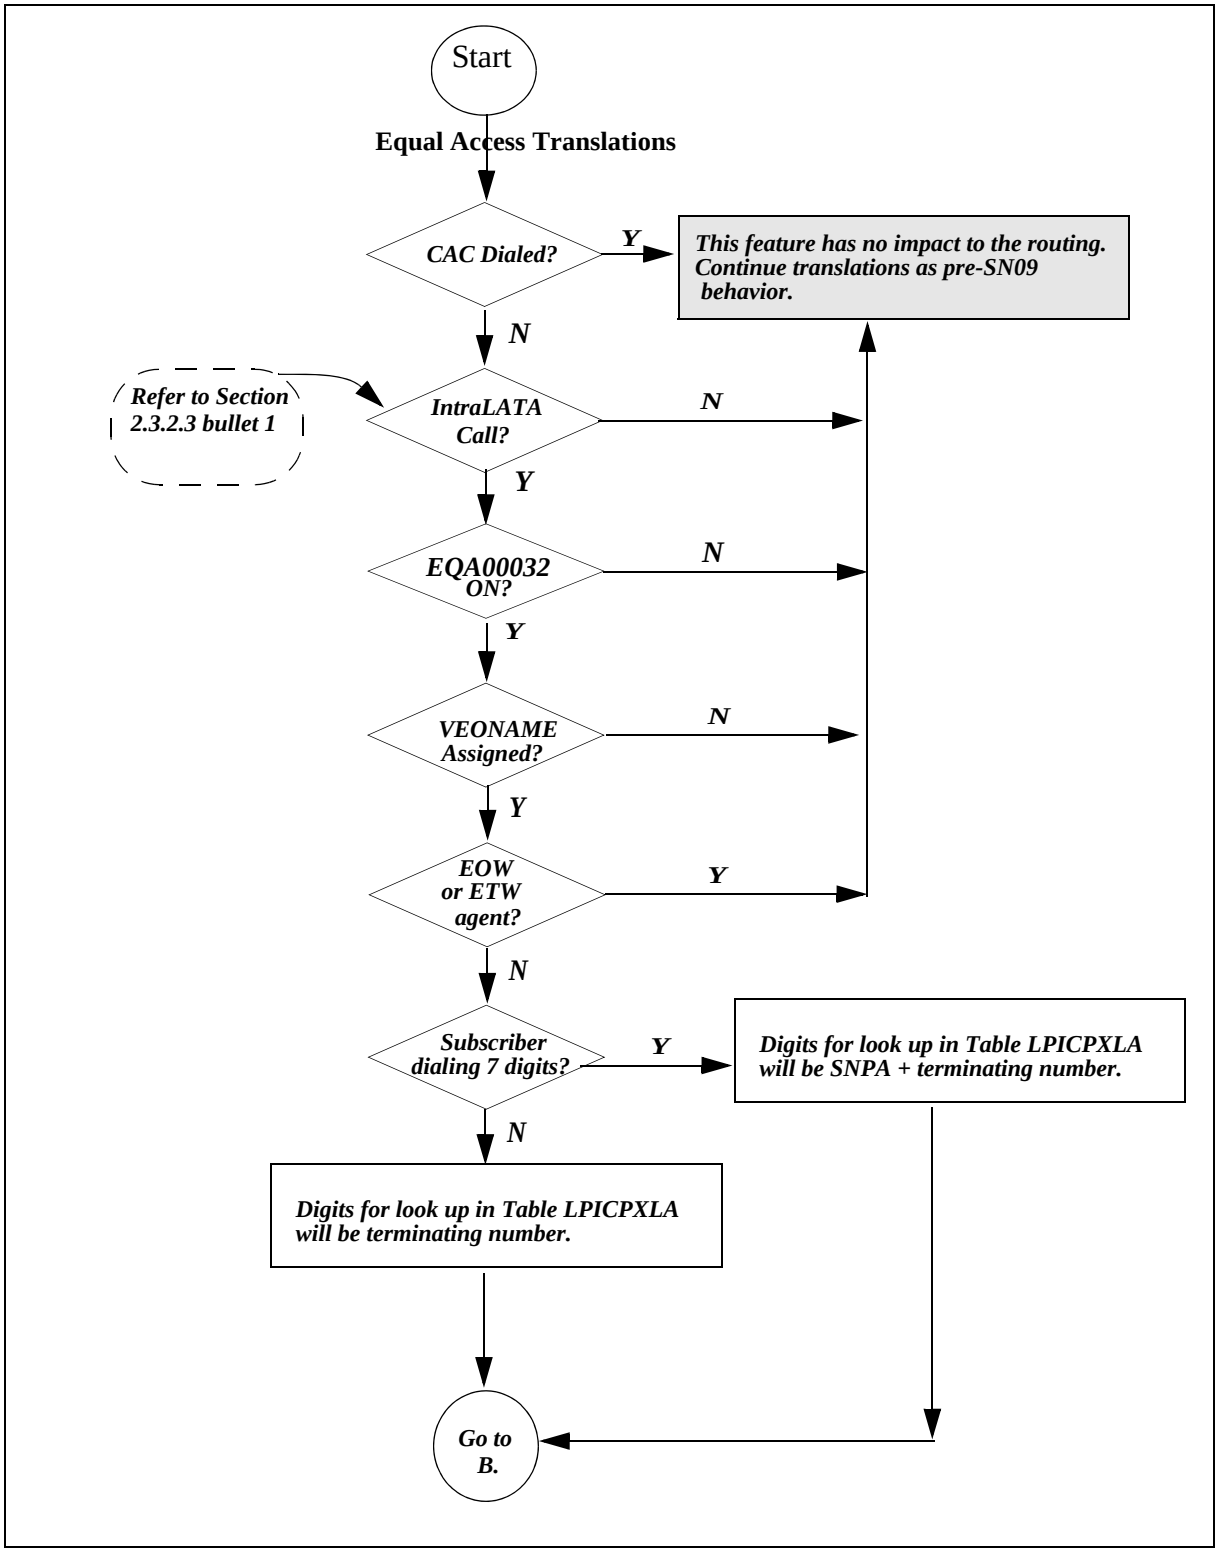


Figure 7 Continued - Equal Access Translations

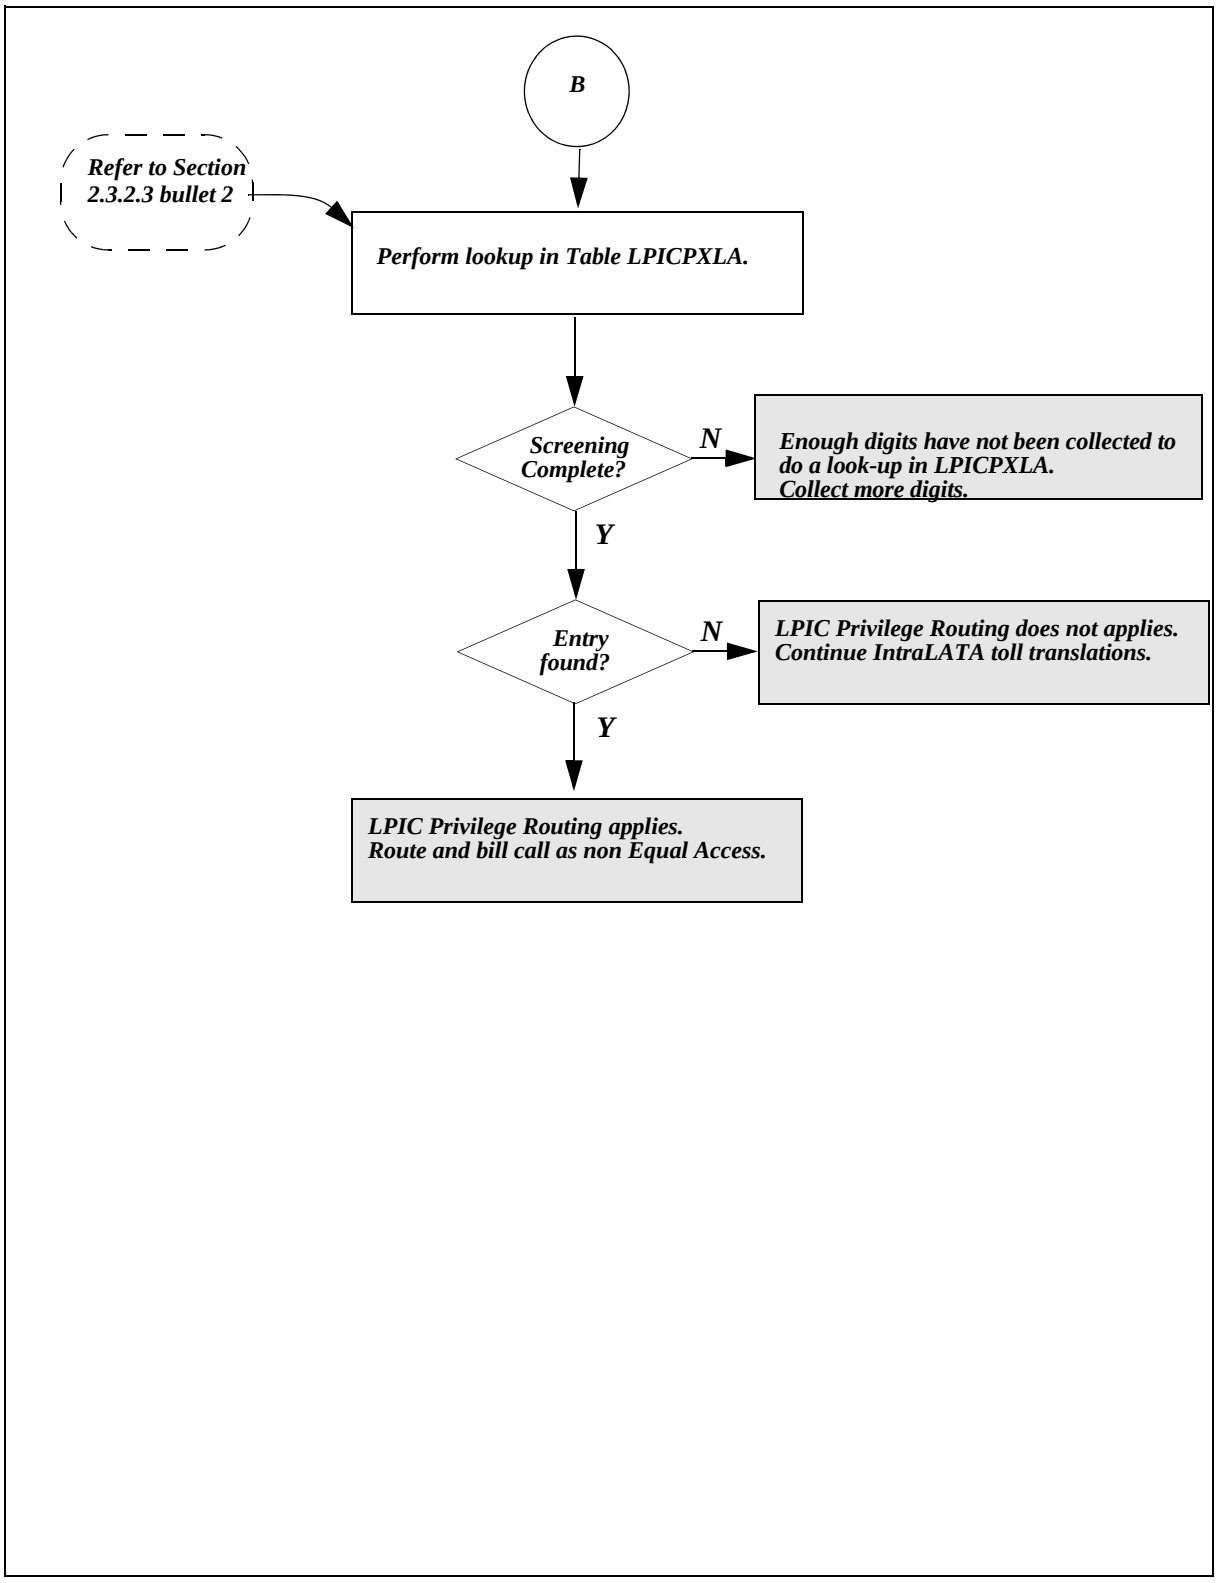

30.3.2.4 Traver Enhancements

The DMS100/CS2000 EO Traver software is enhanced to support the display of new option VEONAME and to display the contents of new table LPICPXLA. The Traver enhancements are active only when SOC EQA00032 is set to ON and option VEONAME is provisioned for the originator. The following chart describes the Traver impact for the different combinations. Figures 8 through 11 are examples of the modified Traver output.

Table 3 Traver Impact

SOC State	VEONAME Assigned	LPICPXLA entry found?	Traver Impact
IDLE	No	N/A	There will be no new messages in the traver output.
IDLE	Yes	No	There will be no new messages in the traver output.
IDLE	Yes	Yes	There will be no new messages in the traver output.
ON	No	N/A	There will be no new messages in the traver output.
ON	Yes	No	New Message after displaying Table LATAXLA data: **'TABLE LPICPXLA** **TUPLE NOT FOUND '**
ON	Yes	Yes	New Message after displaying Table LATAXLA data: **'TABLE LPICPXLA** **VEO1 919528** ... **OPERATING TELCO WILL HANDLE THIS CALL'**

30.3.2.5 Service Interactions with LPIC Privilege Routing

30.3.2.5.1 Interactions with Existing EA Translation Capabilities

The interactions between existing EA LPIC translation capabilities and the LPIC Privilege Routing are addressed below.

0+ Local Routing:

SOC EQA00015[1], "IntraLATA PIC Enhancements Phase 1," provides the flexibility to route 0+ local calls to the LEC, the subscriber's LPIC, or a designated carrier. Office parameter ZERO_PLUS_LOCAL_CARRIER in combination with SOC EQA00015 controls the switch behavior. If the 0+ local capability determines the call will route to the carrier provisioned for parameter ZERO_PLUS_LOCAL_CARRIER or to the LPIC, the call is handled as an LPIC toll call.

The LPIC Privilege Routing capability introduced by this activity adheres to the same behavior, and performs screening for the called NPANXX in table LPICPXLA when SOC EQA00032 is ON and the originator has the VEONAME option assigned. If the LPIC Privilege Routing applies, the call will route to the LEC as a non-EA call.

If SOC EQA00015 is OFF, the call will route to the LEC as a non-EA call (this behavior is unchanged by the functionality of this activity).

If NILC or USE_PREVIOUS is provisioned for parameter ZERO_PLUS_LCL_CARRIER, the call will route to the LEC as a non-EA call (this behavior is unchanged by this activity).

1+ Coin IntraLATA Routing Flexibility:

SOC EQA00015, "IntraLATA PIC Enhancements Phase 1," in combination with field INTRCOIN in table OCCINFO provides the ability to route 1+intraLATA toll *coin* originations to either the LEC, the subscriber's LPIC, or a designated carrier. If the coin 1+intraLATA toll capability determines the call will route to the carrier provisioned for INTRCOIN or to the LPIC, the call is handled as an LPIC toll call.

The LPIC Privilege Routing capability introduced by this activity adheres to this behavior and performs screening for the called NPANXX in table LPICPXLA when SOC EQA00032 is ON and the originator has the VEONAME option assigned. If LPIC Privilege Routing applies, the call will route to the LEC as a non-EA call.

If 'Y NILC' is provisioned for field INTRCOIN, the call will route to the LEC as a non-EA call (this behavior is unchanged by this activity).

If SOC EQA00015 is OFF, the call is handled as an LPIC toll call. The LPIC Privilege Routing capability introduced by this activity adheres to

[1]Introduced by feature AN1811.

this behavior and performs screening for the called NPANXX in table LPICPXLA when SOC EQA00032 is ON and the originator has the VEONAME option assigned. If the LPIC Privilege Routing applies, the call will route to the LEC as a non-EA call.

LATAXLA LPIC Privilege:

SOC EQA00024[1], "Override LPIC Privilege," provides the ability to mark intraLATA codes as privilege on a per LATA basis via table LATAXLA. When EQA00024 is ON, LPIC calls are handled by the LEC for those codes that are provisioned as privilege in table LATAXLA.

The LPIC Privilege Routing capability introduced by this activity provides the same capability as EQA00024, but on a per VEO basis. EQA00032 and EQA00024 are independent of each other. The LPIC Privilege Routing capability takes precedence when SOC EQA00032 is ON and VEONAME is provisioned on the originating agent. If the originator does not have VEONAME provisioned or SOC EQA00032 is IDLE, the new LPIC Privilege Routing capability does not apply. In this case SOC EQA00024 continues to be used to provide intraLATA privilege routing.

Table LATAXLA NON_EA Datafill:

Table LATAXLA allows NPA/NPANXX codes to be provisioned as a NON_EA calltype. If NON_EA calltypes, the call routes as a non-EA call. Casual access dialing to NON_EA codes is not permitted. This behavior takes precedence over the LPIC Privilege Routing feature. If the dialed number (NPA or NPANXX) is provisioned as NON_EA in table LATAXLA, the call will be routed as a non-EA call. In this case, table LPICPXLA is not referenced.

Alternate Service Provider:

An alternate service provider can be specified for any of the following services:

In-Session Activation (ISA): AQ1700

Special Delivery Service (SDS): AQ1335

Universal Voice Messaging (UVM): AQ1303

Virtual Call Framework (VCF): AJ4936

Who's Calling (WC): A59012655

These services specifically request an alternate carrier be used to complete the call.

With pre-SN09 behavior, privilege routing takes precedence over the alternate carrier. If table LATAXLA is provisioned as privilege, the call is handled by the LEC regardless of whether an alternate carrier is provided

[1]Introduced by feature AN1811.

by the service. This applies to both “Override LPIC Privilege” (SOC EQA00024), and interLATA privilege in table LATAXLA.

The LPIC Privilege Routing capability introduced by this feature is consistent with this behavior and takes precedence over alternate carrier. Screening will be performed for intraLATA toll NPANXX codes in table LPICPXLA when SOC EQA00032 is ON and the originator has the VEONAME option assigned. If LPIC privilege routing applies, the call will route to the LEC as a non-EA call.

30.3.2.5.2 Advanced Intelligent Networks (AIN)

This feature also interacts with AIN response translations. When AIN database response returns an intraLATA routing number, SOC EQA00032 is active, and VEONAME is associated, the new Table LPICPXLA is accessed to determine if LPIC privilege applies.

The routing number is always used as part of the index into LPICPXLA. The other part of the index is the VEONAME, which is retrieved as discussed below:

- When AIN response translation routes through a VFG the existing behavior is to retrieve the LATA name associated with the subscriber, and not the VFG. The LPIC feature is consistent with this behavior. The VEONAME is retrieved from the subscriber for intraLATA calls when the LPIC SOC EQA00032 is active. In these cases the LPICPXLA will be indexed using the subscriber’s VEONAME and the routing number returned in the AIN DB response.
- Using AIN it is possible to alter the translation through table XLAMAP and table PXLAMAP. Either the pretranslator name or the LINEATTR index can be altered. In this case deriving the VEONAME is dependent on whether the AIN translation specifies a new pretranslator name or a new LINEATTR index:
  - — If the AIN translation specifies a new pretranslator name, the VEONAME is derived from the subscriber.
  - — If the AIN translation specifies a new LINEATTR index, the VEONAME is derived based on the XLAPLAN associated to the new LINEATTR.
- The use of the LARP capability provides a method to override various translation attributes for the AIN response translation via option LARP in Table TRIGITM. These translation attributes include LINEATTR, XLAPLAN, and RATEAREA indices. LARP TRAVER option[1] and call processing derives the LATANAME associated with the LARP datafill in Table TRIGITM. This feature will adhere to this behavior and derive the

[1] Introduced by feature A59022554.

VEONAME associated with the XLAPLAN index provisioned in table TRIGITM.

- All other cases derive the VEONAME from the originating agent.

30.3.2.5.3 Local Number Portability (LNP)

LNP calls perform translations twice. The first one is referred to as the pre-query translation which occurs prior to the sending the query to the LNP database. The second one is referred to as the post-query translation which occurs after the receipt of the LNP database response.

If SOC NPE00005[1], "1000 Blk Nbr Pooling," is ON, the LPIC Privilege Routing capability introduced by this activity will use the LATAXLA results from the pre-query translation. Specifically, if the pre-query LATAXLA result determines the call is intraLATA, the LPIC privilege capability performs a lookup in table LPICPXLA if LPIC SOC EQA00032 is ON and the VEONAME is assigned to the originator. The ported DN is used for the look-up in table LPICPXLA.

IF NPE00005 is IDLE, the LPIC Privilege Routing capability uses the LATAXLA results from the post-query translation. Specifically, if the post-query LATAXLA result determines the call is intraLATA, the LPIC Privilege Routing capability performs a lookup in table LPICPXLA if the LPIC Privilege Routing SOC is ON and the VEONAME is assigned to the originator. The ported DN is used for the look-up in table LPICPXLA.

The LNP TRAVER option LNPAR provides the ability to simulate an SCP response containing an FLRN, HLRN, or ported DN. The LPIC Privilege Routing capability introduced by this activity requires the use of option LNPAR to correctly display the contents of table LPICPXLA. VEONAME is derived the same for TRAVER as with call processing but the NPANXX used to access LPICPXLA is derived differently. Specifically, the LNPAR option contains the ported DN which is used as the other part of the key to Table LPICPXLA. Thus, TRAVER is consistent with call processing.

The syntax for the LNPAR option is as follows:

TRAVER L 6215000 N CDN NA <routing #> AINRES R01 LNPAR <ported DN> B

Where an LRN or the ported DN can be entered as the <routing #> and a 10 digit DN or 'N' can be entered for <ported DN>.

[1]Introduced by activity A59012192.

30.3.2.5.4 In-Session Activation (ISA)

In-Session Activation (ISA)[1] is an originating line service that is activated when the originator places a call and the called party is either busy or a ringing timeout occurs. When either of these two conditions occur, the switch software performs *called party screening* to determine whether to offer the ISA service. The *called party screening* function looks at various call characteristics to determine whether to activate ISA. With pre-SN09 behavior, if the call is provisioned as privilege in table LATAXLA, the ISA service is offered. This applies to both intraLATA and interLATA privilege in table LATAXLA. The LPIC Privilege Routing capability will be consistent with this behavior and ISA service will be offered for intraLATA calls if SOC EQA00032 is ON, the originator has the VEONAME option assigned, and the NPANXX code is provisioned in table LPICPXLA. If the service redirects the call to a new number, LPIC Privilege Routing capability may apply.

30.3.2.5.5 Special Delivery Service (SDS)

Special Delivery Service (SDS)[2] is a feature that provides the originating line with the option to invoke message delivery when the called party is busy or does not answer within an office-defined interval. When either of these two conditions occur, the originating line is connected to a Voice Messaging System (VMS) either directly via an SMDI link or indirectly via an outgoing ISUP trunk.

Prior to terminating to VMS, the SDS features performs *call characteristics screening* to determine whether to offer the SDS service. The *call characteristics screening* function looks at various call characteristics to determine whether to activate SDS. With pre-SN09 behavior, if the call is provisioned as intraLATA privilege in table LATAXLA, the SDS service is offered. The LPIC Privilege Routing capability will be consistent with this behavior. The SDS service will be offered for intraLATA calls if the LPIC SOC EQA00032 is ON, the originator has the VEONAME option assigned and the NPANXX code is provisioned in table LPICPXLA. If the service redirects the call to a new number, LPIC Privilege Routing capability may apply.

30.3.2.5.6 Call Forwarding (CFW) Interactions

Call ForWarding (CFW) allows a subscriber to redirect a call to a new number. The LPIC feature interacts with CFW since it is possible to redirect a call to an IntraLATA number. For intraLATA calls LPIC privilege routing applies if the LPIC SOC EQA00032 is ON, the redirecting agent has the VEONAME option assigned, and the NPANXX code of the forwarding number is provisioned in table LPICPXLA.

[1]Introduced by activity AQ1700.

[2]Introduced by activity AQ1335.

30.3.2.5.7 IntraLATA Full Carrier Toll Denied (FCTDNTRA)

Subscribers may have option FCTDNTRA assigned to their phone. This option functionality is controlled by SOC EQA00015[1]. Subscribers assigned this option are either prohibited from making toll calls using any carrier, or are allowed to have access to a limited number of carriers. Since calls being handled by LPIC Privilege Routing feature will be terminated by the LEC, the FCTDNTRA functionality does not block the call.

30.3.2.5.8 Toll DeNied (TDN)

Subscribers may have the option Toll DeNied (TDN) assigned to their phone. This option restricts an originator from making toll calls. Since the privilege codes for LPIC Privilege Routing are treated as toll codes, originating agents with TDN shall be blocked from accessing privilege codes.

30.4 Hardware Requirements or Dependencies

Not applicable

30.5 Software Requirements or Dependencies

Not applicable

30.6 Limitations and restrictions

The following limitations and restrictions apply to Virtual End Office (VEO) partitioning capability:

- VEO capability is not supported by DMS200. It is only supported by DMS100/CS2000.
- VEO is only for public translations capabilities.
- VEONAME option can not be assigned in Table XLAPLAN or Table CXGRP with VEO name of NILV (NIL VEO name).
- Maximum 999 VEOs are supported.

The following limitations and restrictions apply to the LPIC Privilege Routing functionality:

- EOW (Enhanced Outwats) and ETW (Enhanced Two-Way WATS) originating agents are not supported.
- MDC EWATS which was introduced by feature AF1664 and AF7559 is not supported.
- CALEA is not supported.
- Up to six-digit (NPANXX) codes are allowed to be provisioned as privilege codes in table LPICPXLA.

[1]Introduced by activity AN1811.

- The maximum size of table LPICPXLA will be determined by the digits pattern used in the table LPICPXLA, and the total number of VEO names provisioned in table VEONAME.
- P2 trunks are not supported.
- AIN local trunk capability[1] allows a call to reroute to a carrier when incoming on local trunks (i.e. TI, T2, IT, ATC). AIN local trunk capability is not supported by this feature.
- Packet (X.25, X.75) translations are not supported.
- This feature is not supported on non-conforming end offices.

30.7 Interactions

Refer to Section 30.3.2.5 “Service Interactions with LPIC Privilege Routing” on page 271.

30.8 Glossary

Term	Description
AIN	Advanced Intelligent Network
CAC	Carrier Access Code
CALEA	Communications Assistance for Law Enforcement Act
CFW	Call Forwarding
EA	Equal Access
EO	End Office
EOW	Enhanced OutWats
ETW	Enhanced Two-Way WATS
FLRN	Foreign Location Routing Number
HLRN	Home Location Routing Number
ISA	In-Session Activation
LARP	Line Attribute Response Processing
LATA	Local Access and Transport Area
LCC	Line Class Code
LEC	Local Exchange Carrier
LNP	Local Number Portability

[1]Introduced by feature AJ3999.

Term	Description

31: Functional Description (FN) A00009092

31.1 Feature name and Feature ID

A0009092: CS2K MSM SIP Lines Cisco 7960 Client

31.2 Description

This feature covers the integration of the Cisco 7960 SIP-enabled IP Phone with the CS2000 MSM SIP Lines program. This document details the functional requirements for the phone and CS2000 MSM 1.0 compliancy to the requirements.

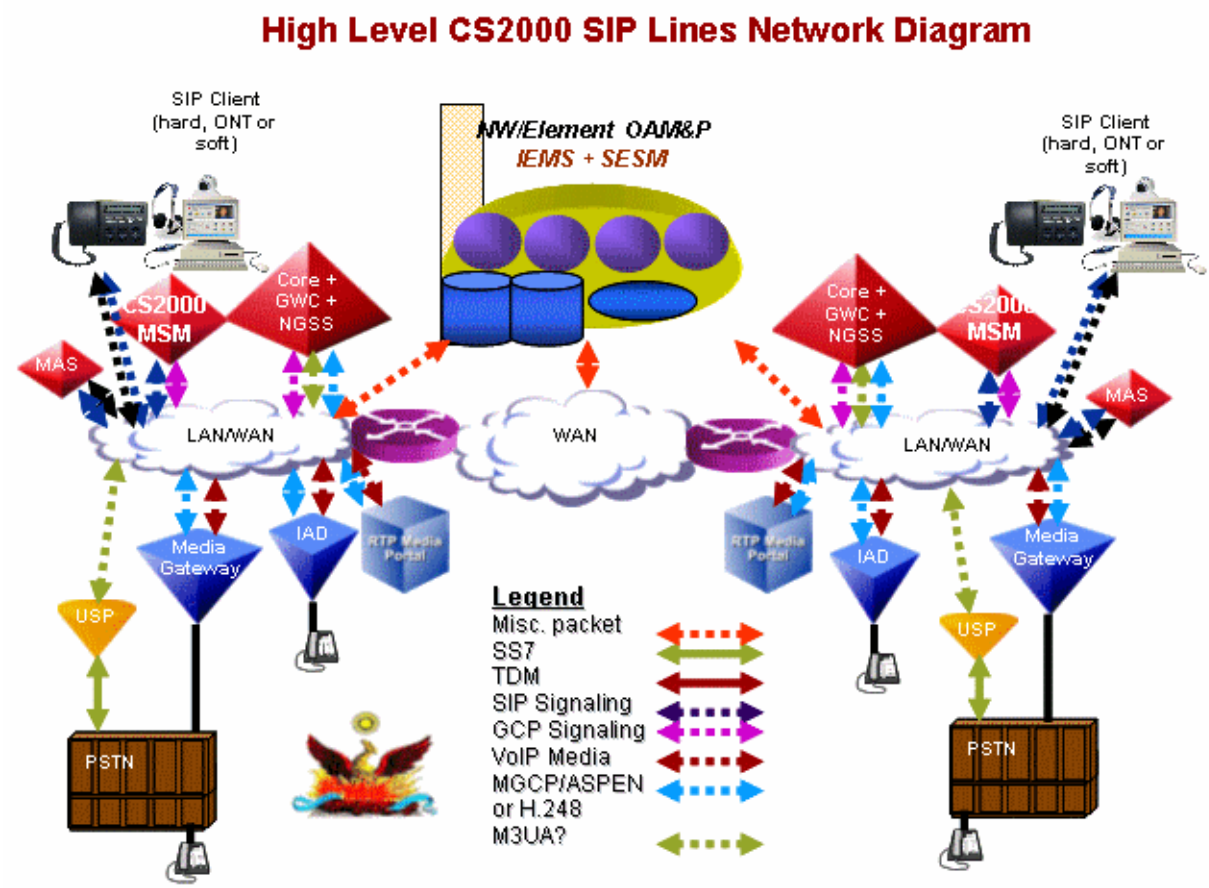
The Cisco 7960 requirements are broken into 3 categories:

1) Call Processing Services and Functionality

2) Software Download and configuration

3) NAT traversal

31.2.1 Hardware Requirements or Dependencies



31.2.2 Software Requirements or Dependencies

This feature is part of the MCP 9.0 Release. The Cisco Firmware release is POS3-07-4-00.sb2 (version 7.4)

The following requirements compliancy matrix lists both the feature requirements for the phone and which features are supported for CS2000 SS 1.0 in SN09.

Note: An asterisk (*) in the “Supported” column indicates the requirement is supported by the phone but requires development work on the CS2000 SS.

Feature/Capability	Supported on the Cisco 7960	Additional Notes
911	SN09	Routing provided by the core
Address book (personal)	No	

AIN services	n/a	
Analog signaling	n/a	
Answering Machine	n/a	
Assistant Console (Boss/ Admin)	n/a	
Audible voice identity delivery	n/a	
Basic inbound call delivery	SN09	
Bridged lines	n/a	
Bulletins	No	
Busy line verification	n/a	
Call back to busy line (ACBAR)	SN10	Done via feature activation on the core
Call forward locally on 7960	SN09	Programmed locally via softkeys on the phone
Call Forward via Personal Agent	SN09	
Call Forward via CS2000 Core	SN09* (if via FAC)	Handled by the core
Call Park	No	Not supported in SIP functionality on the phone – not available in standalone solution
Call rejection	n/a	
Call return	SN09 * (if via FAC)	Handled at the core
Call subjects	No	
Call tracing	SN09 * (if via FAC)	Handled at the core
Call waiting	SN09	User configurable on the phone
Call waiting disable	SN09	User configurable on the phone
Caller ID	SN09	User configurable on the phone
Click to call	n/a	Not initiated from the phone
Clipboard	n/a	
CODEC - G711	SN09	
CODEC - G729	SN09	
Conference (Ad hoc; 3-way calling only)	SN09	Phone provides the audio mixing at G.711 only – max 3-way call
6-way Adhoc conference	n/a	Not supported; max 3-way mixing
Converged Desktop	SN10	
Decline	n/a	Not supported by the phone
Device restrictions	n/a	
Direct connect	No	
Directory (global address via LDAP)	No	
Distinctive ringing	No	

Do Not Disturb	SN09	User configurable on the phone
File exchange	n/a	
Firewall support	SN09 *	Support for non-symmetric firewalls
Friends online	No	
Group alerting	n/a	
Hold (automatic hold)	SN09	Basic hold/retrieve performed on the phone
Hotline	n/a	
Ignore	n/a	
Import Outlook contacts	n/a	
Inbound call delivery to a group of lines	n/a	
Inbox	SN09	Phone has “Received Calls” and “Missed Calls” directories
Instant Message (IM)	No	Not supported by the phone
Lawful intercept (via Core)	SN09	Done by the core
Meet me Audio Conferencing	SN09 *	
Message Waiting Indicator (MWI)	SN09	
Multiple Lines/Users supported	SN09	Supports multiple users logged into the same device
Outbound call dialing	SN09	
Outbound call routing	SN09	
Outbound call screening	SN10	
Outbox	SN09	Phone has a “Placed Calls” directory
Outlook integration	n/a	
Picture ID	No	
Presence	n/a	SIP Presence not supported by the phone. “On the Phone” presence available via the SS
Profile manager	n/a	
Protocol - TCP	No	
Protocol - TLS	No	
Protocol - UDP	SN09	
Quality of Service (QoS) Reporting	n/a	
QoS Type Of Service (ToS) Marking	SN09	
Recursive calling (party line)	n/a	
Redirect	n/a	
Reject reasons	No	

Screening and routing (follow me, sequential ringing)	n/a	
Search options (address books)	No	
Server selection	SN09	Admin can provision a single Session Manager Address at the outbound proxy
Sharing	n/a	
Speed dialing	SN10	
Telemetry	n/a	
Transfer – Blind	SN09	Transfer failure cannot be retrieved
Transfer – Consult	SN09	Transfer failure cannot be retrieved
User configurable settings – requires user knowledge of phone configuration password	SN09 (See Section 2.5 below)	
User controlled codec selection – requires user knowledge of phone configuration password	SN09	
Video (video on demand)	n/a	
Voice mail	SN09	
Web push and co-browsing	n/a	
Whiteboard	n/a	

31.3 Limitations and restrictions

Certain call processing limitations of the 7960 result in the following services limitations:

- Calling Name/Number Blocking must be done via star-code activation on the core. The 7960 SIP implementation of this feature is not compatible with the CS2000 SS.
- Call Transfer is accomplished using the SIP REFER method. Transfers that fail cannot be retrieved due to the implementation on the 7960.
- Ad-hoc conferencing is accomplished as a 3-way call. The Cisco 7960 provides the audio mixing at the device itself. The 7960 only mixes G.711 packets, thus any existing legs negotiated to G.729 will attempt to be renegotiated to G.711. If a device does not support the G.711 codec then it cannot be included in a 3-way conference on the phone. The maximum ad-hoc conference size is 3. 6-way conferencing must be done via an external conferencing server.
- Presence is not supported from the phone. Therefore, all presence indications or updates must be derived from the active call state or registration state. By default, the CS2000 SS will support a presence state

of “connected” for a registered user, “unavailable offline” for a user who is not registered, and “On the Phone” for a user who is in an active call. Any additional presence states must be derived as if this device were a “Non SIP Lines device” by the core.

In addition, CS2000 SS SIP Lines will not support initiating a remote reset of the Cisco 7960 phone (via NOTIFY) for this release. Since reset remote is not supported, the phones cannot initiate a firmware upgrade without manual intervention. All firmware upgrades must be done manually via editing the configuration files located on the TFTP server and resetting the phone. Once the phone is reset, it will compare the current firmware load in flash with the load specified on the TFTP Server configuration file and initiate a download of the new firmware if the loads do not match. The network administrator is responsible for scheduling and initiating the reset of the phones for firmware upgrade. In addition, the TFTP server will not be integrated with the CS2000 SS solution, but rather a separate server from any other CS2000 SS component.

Note: Currently, there is no security mechanism in place to authenticate a remote reboot request via NOTIFY.

Likewise, provisioning of a CS2000 SS SIP Lines user will not automatically generate a phone specific configuration file on the TFTP server. The admin is responsible for creating and maintaining all the configuration files on the TFTP server for each phone in the network.

The Cisco phone does not provide a NAT traversal mechanism to indicate in SIP signaling the presence of a firewall between the client and the CS2000 SS. To compensate for this, the CS2000 SS will compare the UDP packet source IP address against the SIP Via Header IP address to determine whether or not to treat this client as a firewalled client and replace the contact IP address appropriately. The mechanism for keeping the firewall binding active will be a combination of the periodic maintenance audit via the OPTIONS message and a reduced registration expiry timer. However, if a NAT device dynamically re-binds a new IP and port to the Cisco 7960 after the phone is initially registered, a period of time will exist when calls can no longer terminate to the Cisco phone due to the stale NAT binding. This period of time can be up to the configured registration expiry timer. This firewall detection algorithm will not work for “symmetric” firewall solutions, where the IP address on both sides of the NAT device remain the same and only the port changes. Thus, symmetric firewall solutions are not supported for the first release.

31.4 Interactions

Where applicable, services initiated from the Cisco phone will use existing SIP service implementation to accomplish the desired feature. However, due to the

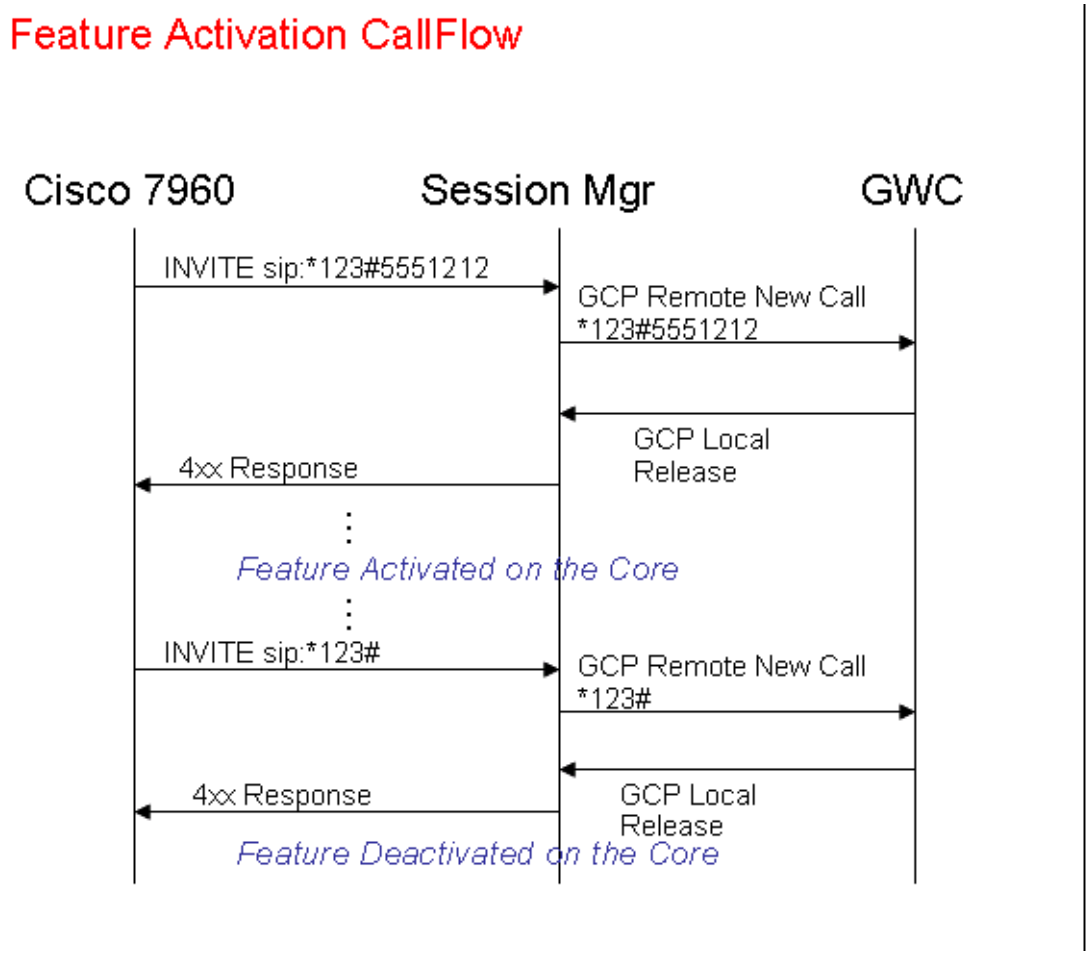
complex suite of services available to SIP Lines on the CS2000 Core, some feature activation will be done via star-code feature activation codes (FACs).

These services can be activated or deactivated by the phone via the configuration menu system:

- Do Not Disturb
- Auto-Completion of numbers
- Call Waiting
- Call Hold Ringback
- Stutter Message Waiting
- Auto-Answer (Intercom)
- Speed Dial (up to 5 numbers)
- Call Forward Unconditional

The services below will be permanently disabled on the phone and only available thru FACs. See the proposed call flow below for an indication of how the digits will be presented to the core.

- Caller ID Blocking
- Anonymous Call Reject



Call Forward is available on the phone (CFU) and also via FACs at the core.

31.5 Recommended Configuration

The following recommended settings should be used to assure interoperability between the 7960 and the CS2000 SS. The files reside in the root directory of an available TFTP server that all the 7960 phones are configured to use.

31.5.1 Common SIP Parameters

The SIPDefault.cnf file contains the common sip parameters needed by all the 7960 devices. These parameters control the default behavior of the phone and provide the phone the Session Server address and domain name that should be used. If these default parameters are not applicable to all 7960 phones in the network, then multiple TFTP servers should be used or duplicate parameters included in the phone-specific configuration file detailed in section 2.7.2. The file should be of this general format with only the domain name and IP Addresses highlighted in blue changed:

```
# SIP Default Generic Configuration File

# Image Version
image_version: P0S3-07-4-00

# Proxy Server
proxy1_address: "nortel.com" ; Can be dotted IP or FQDN
proxy2_address: ""           ; Can be dotted IP or FQDN
proxy3_address: ""           ; Can be dotted IP or FQDN
proxy4_address: ""           ; Can be dotted IP or FQDN

####### New Parameters added in Release 3.1 #######

# Allow Transfer to be completed while target phone is still ringing
semi_attended_transfer: 0       ; 0-Disabled, 1-Enabled (default)

# Telnet Level (enable or disable the ability to telnet into the phone)
telnet_level: 2                 ; 0-Disabled (default), 1-Enabled, 2-Privileged

####### New Parameters added in Release 4.0 #######

# XML URLs
```

```
services_url: ""                ; URL for external Phone Services
directory_url: ""               ; URL for external Directory location
logo_url: ""                    ; URL for branding logo to be used on phone display

# HTTP Proxy Support
http_proxy_addr: ""             ; Address of HTTP Proxy server
http_proxy_port: 80             ; Port of HTTP Proxy Server (80-default)

# Dynamic DNS/TFTP Support
dyn_dns_addr_1: ""              ; restricted to dotted IP
dyn_dns_addr_2: ""              ; restricted to dotted IP
dyn_tftp_addr: ""               ; restricted to dotted IP

# Remote Party ID
remote_party_id: 0              ; 0-Disabled (default), 1-Enabled
```

31.5.2 Device Specific Parameters

The device-specific file of the filename format SIP<MACAddress>.cnf is used to specify parameters that apply only to a specific 7960 phone. In addition, parameters included in this file will take precedence over duplicate parameters in the SIPDefault.cnf file. The file should be of this general format with the each user-field matching what is provisioned:

```
# SIP Configuration Generic File

# Line 1 appearance
line1_name: user10

# Line 1 short name
line1_shortname: user10

# Line 1 Registration Authentication
line1_authname: "user10"

# Line 1 Registration Password
line1_password: "1234"

# Line 2 appearance
line2_name: user3

# Line 2 Registration Authentication
line2_authname: "user3"

# Line 2 Registration Password
line2_password: "1234"
```

```
####### New Parameters added in Release 2.0 #######

# All user_parameters have been removed

# Phone Label (Text desired to be displayed in upper right corner)
phone_label: "Phoenix SIP Lines         "; Has no effect on SIP messaging

# Line 1 Display Name (Display name to use for SIP messaging)
line1_displayname: "user10"

# Line 2 Display Name (Display name to use for SIP messaging)
line2_displayname: "user3"

####### New Parameters added in Release 3.0 ######

# Phone Prompt (The prompt that will be displayed on console and telnet)
phone_prompt:   "SIP Phone"      ; Limited to 15 characters (Default - SIP Phone)

# Phone Password (Password to be used for console or telnet login)
phone_password: "cisco" ; Limited to 31 characters (Default - cisco)

# User classifcation used when Registering [ none(default), phone, ip ]
user_info: none
```

31.5.3 Dialplan Definition

Finally, the dialplan.xml file should have the following entry to allow the proper handling of FAC star-code processing:

```
<DIALTEMPLATE>
    <TEMPLATE MATCH="\*.*#,*" Timeout="5"/>      <!-- Anything else -->
</DIALTEMPLATE>
```

31.6 Glossary

Term	Description
FAC	Feature Activation Code
NAT	Network Address Translation
TFTP	Trivial File Transfer Protocol
SS	Session Server

32: Functional Description (FN): A00009129

32.1 Feature name and Feature ID

A00009129: Controlled Hot Swact.

32.2 Description

This feature introduces a controlled hot SWACT capability for the CS 2000 - Compact Call Agent to the same load on the inactive side. A controlled swact is defined as being initiated from the linux CCAMTC map level or system initiated following a REX test.

Prior to this feature, a controlled Swact of the CS 2000 - Compact Call Agent utilizes a warm restart with an associated denial of origination period of approximately 25 seconds. Existing calls are preserved.

This new controlled hot Swact capability significantly reduces the denial of origination period to less than 3 seconds. Existing calls are preserved.

With the significantly reduced denial of origination period, this feature will now initiate a SWACT following a full REX test.

This feature will also provide the ability to set the day of the full REX test. Prior to this feature, the day of the full REX test was hardcoded to Thursday. The time of the REX test is still set via the NODEREXCONTROL tuple in table OFCVAR.

32.3 Hardware Requirements or Dependencies

N/A

32.4 Software Requirements or Dependencies

The minimum software baseline for this feature is a cPCI SOS image based on CSP22 as well a linux ramdisk based on NCGL8.

32.5 Limitations and restrictions

1. The controlled hot swact introduced in this feature is only initiated in two scenarios. From the CCAMTC map and after a REX test. It does NOT include the following.

- SWACT due to hardware/software failure.
- SWACT due to locking of active card on the SAM21EM.
- SWACT initiated by using the SWACT FORCE option in CCAMTC.

2. The CCAMTC map will not display whether the switch is in warm sync or hot sync. This will only be displayed from the CAPCI tool within SOS.

32.6 Interactions

A new SOS CI called CMREXFUL will be created to allow setting the day the full REX will occur.

The SOS CAPCI output will be modified to reflect warm or hot sync state.

The warning message when the swact command is initiated from the linux CCAMTC map level will be modified.

SWACT	Switch Activity

33: Functional Description (FN): A00009153

33.1 Feature name and Feature ID

Feature ID : A00009153, H.323 RLT Development

33.2 Description

Release Link Trunk (RLT) is used to free unused call signaling paths that result from call path changes such as call forwarding and call transfers. RLT is a proprietary function to Nortel that was originally developed for PRI trunks. Therefore, the RLT functionality will only be used by Nortel H323 gateways such as CS 1000 (CS1K).

Since this feature does not address any new functionality for the CS2000 or CS2100, for the remainder of this document, the term CS2K will imply functionality for both CS2000 and CS2100.

Note: A 3rd party H323 Gateway does not use the RLT functionality.

33.2.1 RLT Capability

The RLT functionality and provisioning for CS1K are described outside the scope of this document in "*CS 1000 RLT FS*". The following steps are needed to configure the "*RLT on NI-1 PRI"* capability in the CS2K.

SOC option can be set and verified as shown in the steps below:

```
>soc; soc debug; select option NI000024; (RLT on NI-1 PRI)

>assign rtu <Pass Code> to NI000024
>assign state on to NI000024
OPTION    NAME                                RTU   STATE
     USAGE  LIMIT   UNITS  LAST_CHG
NI000024  RLT on NI-1 PRI        Y     ON       -
     -        -             04/11/17
```

33.2.2 RLT Trunk Provisioning

Each trunk group may be provisioned for RLT capability using the existing MRLT option in the TRKGRP table that was developed for NTNA PRI.

Add the MRLT option to the TRKGRP table.

```
>table trkgrp; format pack ; pos <h323-clli> ; change
     (option set to MRLT)
```

```
<h323-clli> PRA 0 NPDGP NCRT ASEQ N (ISDN 100) $ (MRLT ) $
```

33.2.3 RLT of NTNA PRI trunks

The following section was taken from *NTNA PRI Specification* (NIS A211-1). The H323 RLT functionality is identical to the RLT functionality described in the NTNA PRI specification.

RLT is a feature available on an optional basis which optimizes the usage of NTNA PRI trunks. The following is a typical usage for RLT. Please note that many other scenarios are possible. In this scenario, User A calls User B. This call is referred to as Call 1. Call 1 is routed through the DMS-100 to the PBX. User B then forwards or transfers the call to User C, requesting RLT.

This call (Call 2) is routed through the same DMS-100 as shown in the following figure.

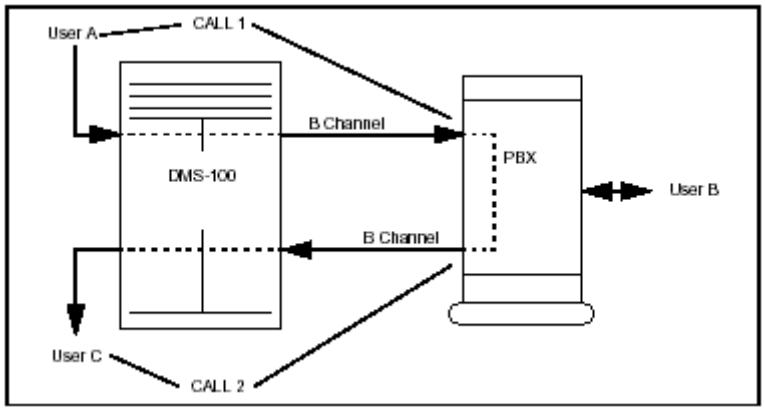

Figure 1: Typical Usage of RLT

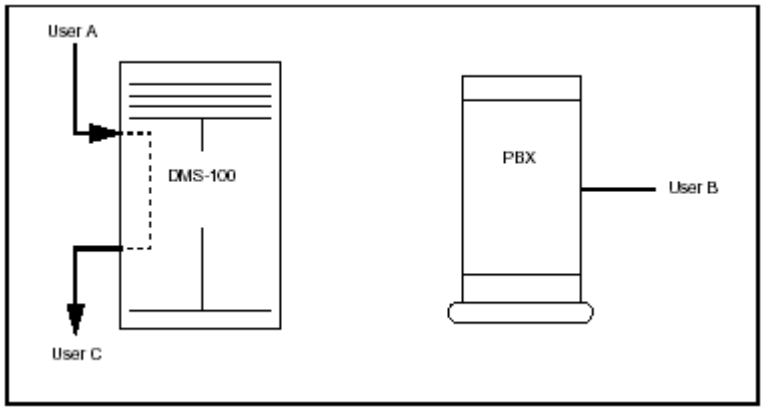

Figure 2: Result of Invoking RLT

When the call to User C is connected, RLT is invoked. The call is bridged between User A and User C at the DMS-100 and the PRI trunks to the PBX are released as shown in Figure 2: Result of Invoking RLT. Any CPE device may be used with this feature if it follows the same user side RLT protocol as described in "NTNA PRI Specification Chapter 5-12: Release Link Trunk (RLT)".

An example of the Q.931 message flow for RLT is shown in the following figure.

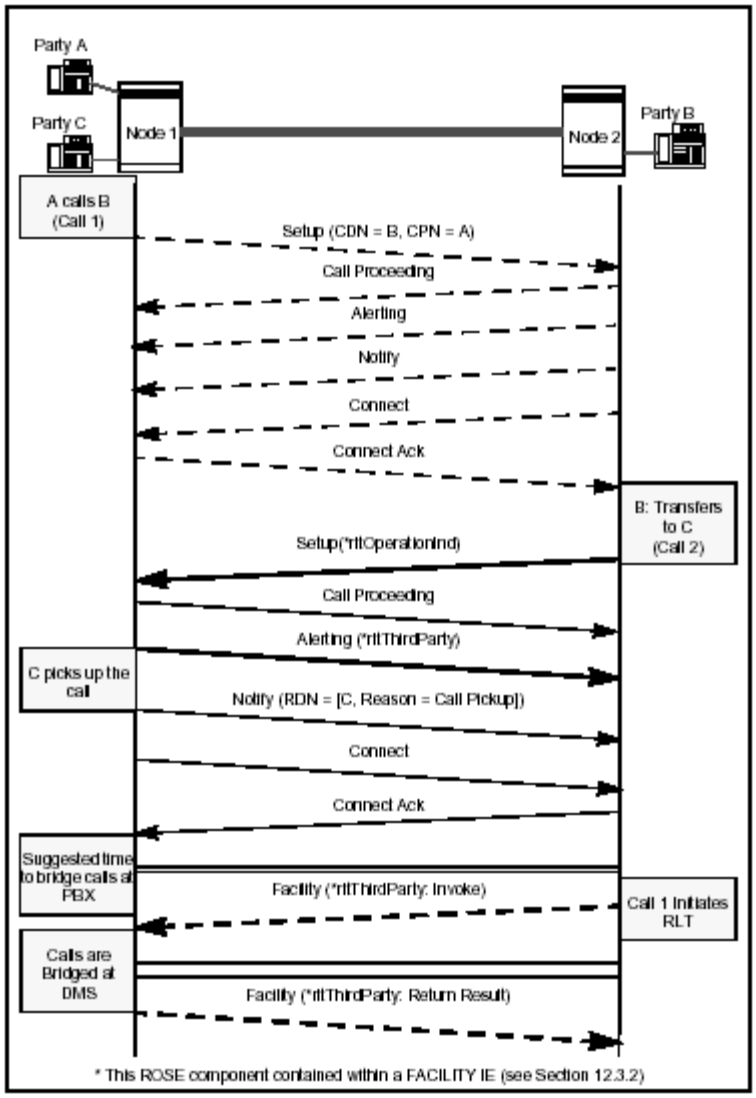

Figure 3: RLT with Call Transfer

33.2.4 Functional Behavior

Assuming RLT functionality has been provisioned in the CS2K and applied to all the H323 NTNA PRI trunk groups, there are two major behavior scenarios.

- "User Side" RLT capability
- "Network Side" RLT capability

33.2.4.1 User Side RLT

The first scenario is shown in the following figure. In this figure, CS1K A is calling CS1K B, and CS1K B call forwards to CS1K C. The invocation of RLT by CS1K B allows the CS2K to bridge the calls, making a new call from CS1K A through the CS2K to CS1K C. This invocation frees up the signaling path between CS1K B and the CS2K. Note that all signaling paths are through the CS2K, since it is the H323 Gate Keeper in this network.

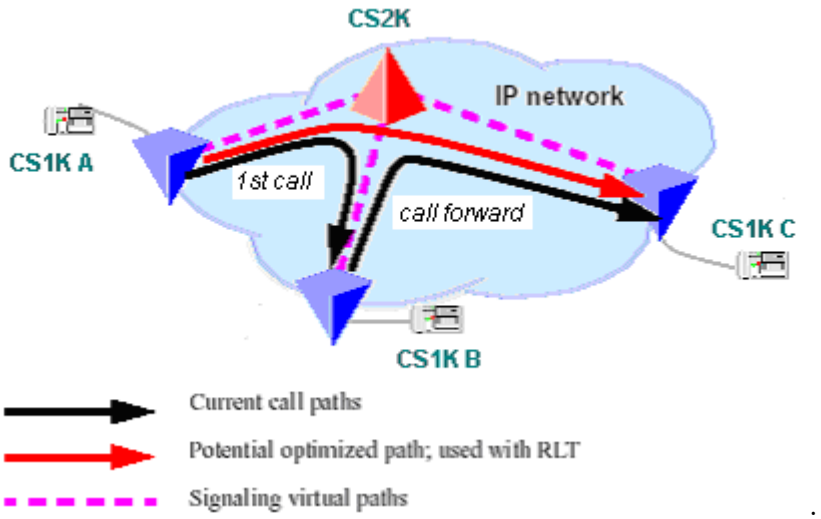

Figure 4 "User Side" RLT Functional Behavior

This scenario will also apply to call transfer in the CS1K. The CS2000 is only capable of processing RLT that is initiated by another H323 gateway such as CS1K; therefore, it is only capable of user side RLT.

33.2.4.2 Network Side RLT (CS 2100 only)

The second scenario is shown in the following figure. In this figure, CS1K A is calling an H323 gateway connected to the CS2100, and CS2100 call forwards to CS1K C. The invocation of RLT by CS2100 allows the CS1K A to bridge the call, making a new call from CS1K A to CS1K C. This invocation frees up the signaling path between CS2100 and the CS1K C.

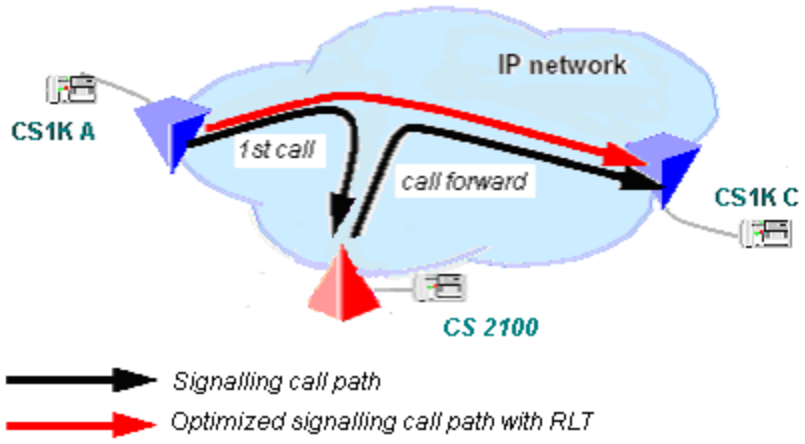

Figure 5 "Network Side" RLT Functional Behavior

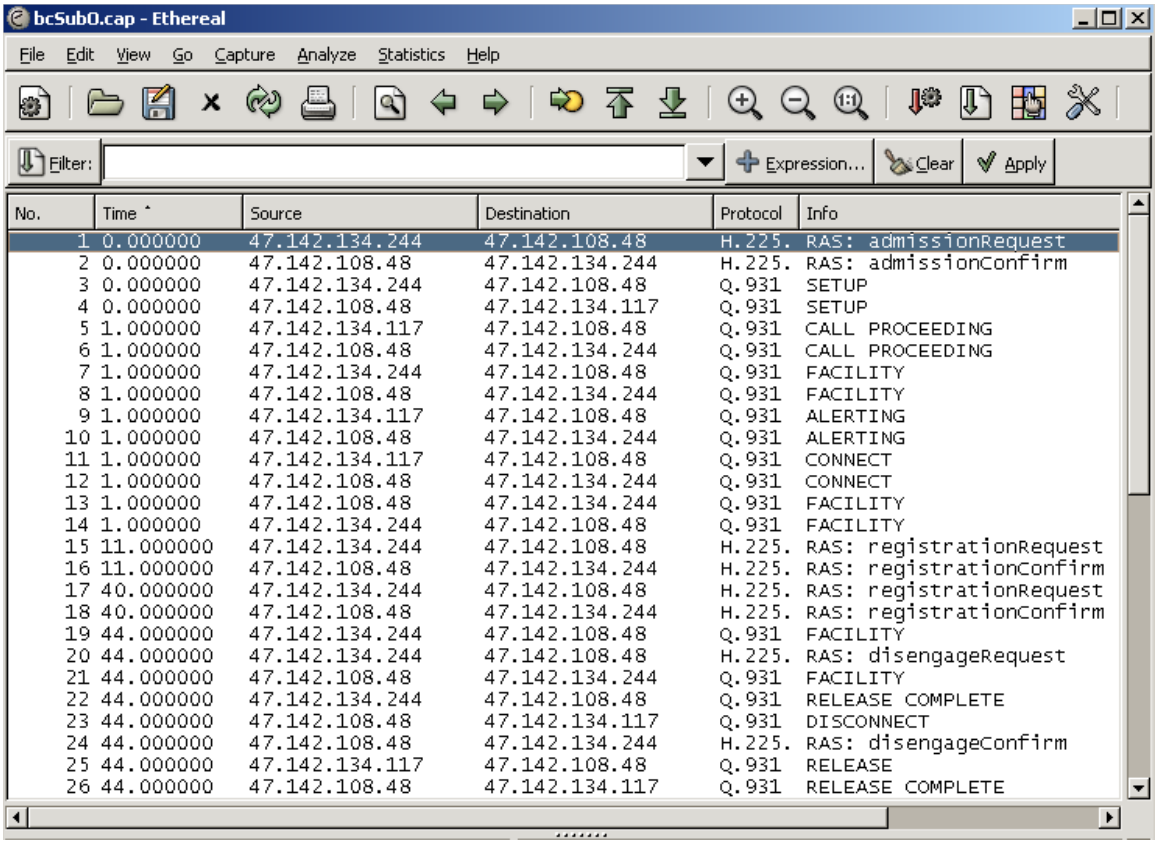
This scenario will also apply to call transfer in the CS 2100. Since the CS2100 is the initiator of the RLT, it is performing the Network side RLT function.

33.2.5 H323 and Q.931 messaging

The H323 call processing messaging uses Q.931 within the H323 message. To demonstrate this, the packet capture tool in the GWC was used to capture packets from the H323 Gateway and packets formatted as Q.931 to send to CS2K. H323 Gateway: IP 47.142.134.244, GWC IP: 47.142.108.48 and CS2K IP: 47.142.134.117.



No.	Time	Source	Destination	Protocol	Info

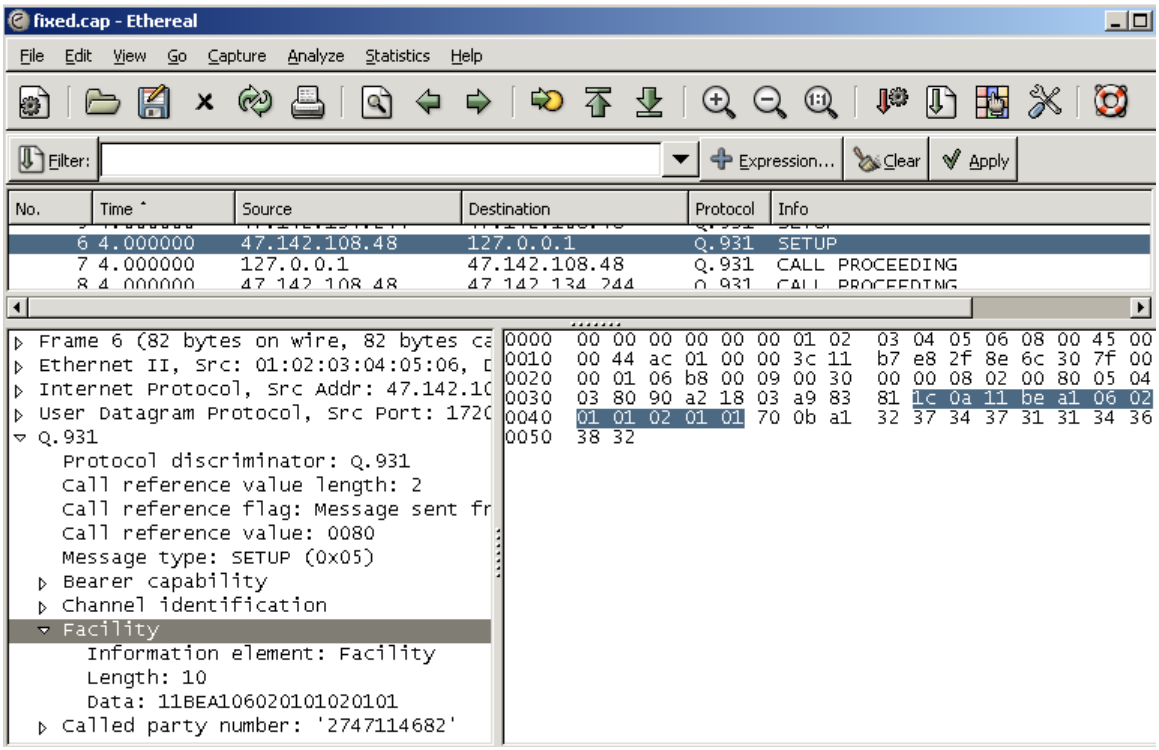
22	44.000000	47.142.134.244	47.142.108.48	Q.931	RELEASE COMPLETE
23	44.000000	47.142.108.48	47.142.134.117	Q.931	DISCONNECT
24	44.000000	47.142.108.48	47.142.134.244	H.225.	RAS: disengageConfirm
25	44.000000	47.142.134.117	47.142.108.48	Q.931	RELEASE
26	44.000000	47.142.108.48	47.142.134.117	Q.931	RELEASE COMPLETE

The GWC receives the H323 messages and creates new Q.931 messages to send to the CS2K. When the GWC receives the CS2K response, it will create a new H323 message from the content of the received message. Therefore, data does not pass from the H323 interface to the CS2K interface transparently. Every component of the Q.931 message is examined and a decision is made within the GWC whether to pass this data. For example, a CS2K DISCONNECT message is translated to a RAS message for H323.

For each message, the content can be viewed using the Ethereal built in decipher of Q.931 as shown in the example below for the SETUP message. In this example, the deciphered message contains the RLT Facility, being sent from the H323 Gateway, forwarded to the CS2K. It is also interesting to note that the call reference value is a 2 byte field on GWC to H323 messages but only one byte is used for the GWC to CS2K.

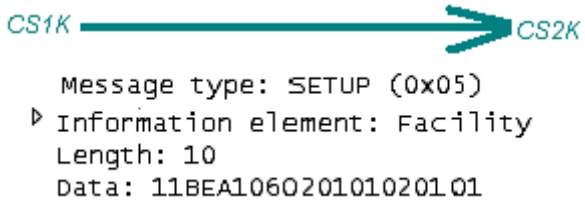


33.2.6 RLT message components

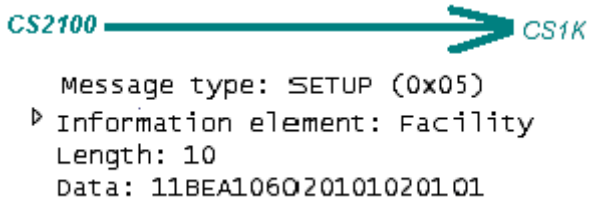
The RLT functionality is accomplished by adding a message component to the SETUP and ALERT messages and uses a new the FACILITY message to invoke RLT.

33.2.6.1 SETUP Message

CS1K SETUP messages for new calls will all contain the facility RLT.

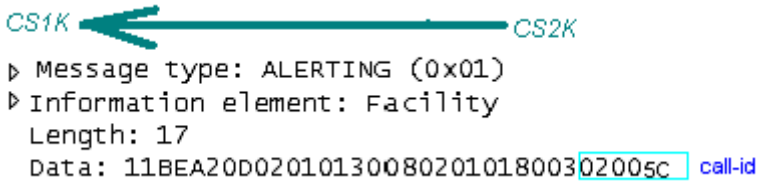


CS2100 SETUP messages for call forward or call transfer will contain the same facility RLT.

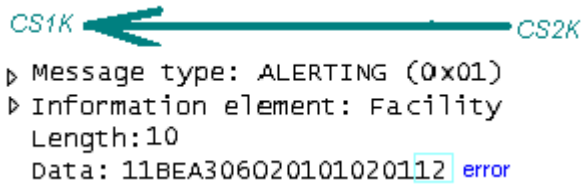


33.2.6.2 ALERT from CS2K

When CS2K is RLT provisioned and it receives an RLT Facility in the SETUP message, CS2K ALERT response messages will have the call-id in the facility RLT.

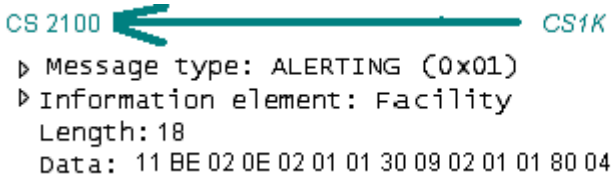


When CS2K is NOT RLT provisioned and it receives an RLT Facility in the SETUP message, CS2K ALERT response message will have and error indicating no RLT support.

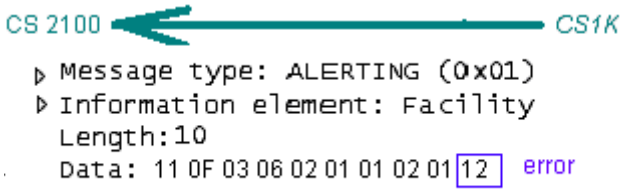


33.2.6.3 ALERT from CS1K

When CS2K sends an RLT Facility in the SETUP message, if CS1K is RLT provisioned, it will send an ALERT response messages with the call-id in the facility RLT.



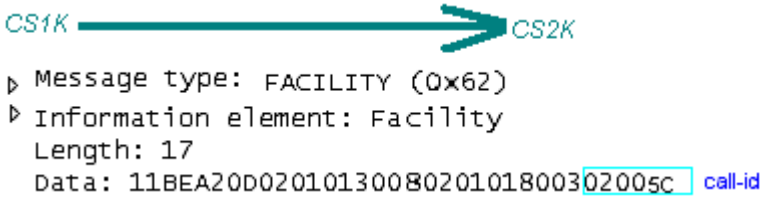
When CS2K sends an RLT Facility in the SETUP message but the CS1K is NOT RLT provisioned it will receive an ALERT response message with error indicating no RLT support.



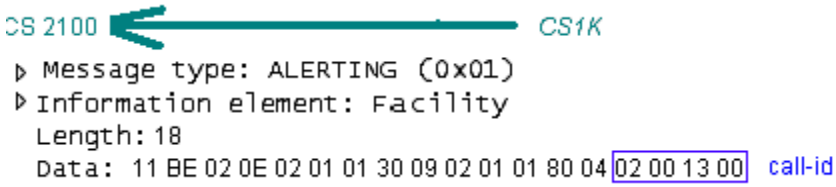
33.2.6.4 FACILITY RLT

After a successful call forward or call transfer, the FACILITY RLT message is used to free up the signaling links. The FACILITY RLT message contains the data returned in the ALERT message. Therefore, a FACILITY RLT message will can only be performed when the CS2K is properly provisioned for RLT on the particular trunk group.

The CS1K will send the FACILITY RLT message with the information it receives from the CS2K ALERT message.

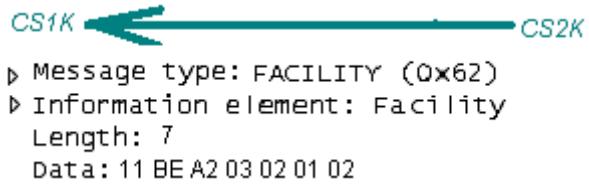


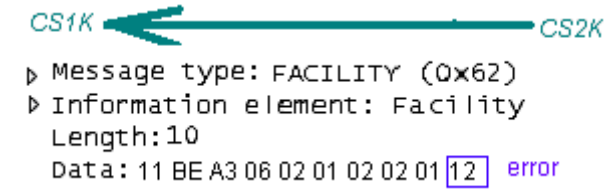
The CS 2100 will send the FACILITY RLT message with the information it receives from the CS1K ALERT message.



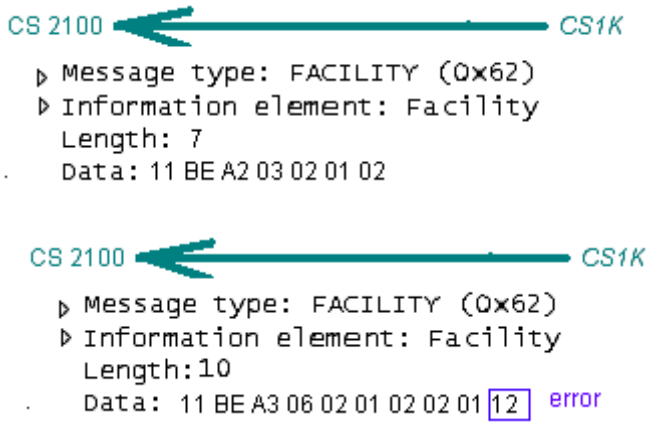
33.2.6.5 FACILITY RLT Response

The CS2K will send a response for the FACILITY RLT success or it will send an error indication.





CS1K response for FACILITY RLT message is the same as the CS2K.



33.3 Hardware Requirements or Dependencies

The H323 RLT capability is a software only component for GWC.

33.4 Software Requirements or Dependencies

The H323 RLT software requirements for the CS1K are described outside the scope of this document in CS1K feature DE2302. Since RLT is requested by the H323 Gateway, the GWC will not perform any RLT action without a Nortel H323 Gateway, such as the CS1K.

33.5 Limitations and restrictions

The CS2K will provide the RLT functionality described in *NTNA PRI Specification* (NIS A211-1).

33.6 Interactions

The RLT functionality is independent of the MCDN tunneling component of the H323.

34: Functional Description (FN): A00009156

34.1 Feature name and Feature ID

USP-Compact Hardware Feature ID : A00009156

34.2 Description

Each USP-Compact blade consists of two components the base card and the daughter card (PMC). The old base card and the old PMC are being phased out by the manufacturer; therefore it is necessary to adapt the USP-Compact software to run on the new replacement hardware.

This feature involves enabling the USP-Compact software that ran under the old hardware to now function on the new hardware. The USP-Compact functionality (from USPc9.0) is not changed by this feature, with the exception of possible performance increases resulting from the new cards (although this is not a required benefit). There are however minor provisioning changes as follows:

- introduction of a new hardware PEC which must be provisioned at commissioning time
- ability to provision the SS7 link interface type to be either T1 or E1 (previously required two separate PEC codes)

  Note: The SAM21 Element Manager is a support application used to provision bootp information queried by USPc at bootup time. It too will have to be modified so that it can support loads introduced by the new hardware.

34.3 Hardware Requirements or Dependencies

The old hardware consisted of two PECs (NTRX51FN and NTRX51FJ) which were selectable by the user and represent the base card and different PMC combo. Each of the two PECs corresponded to different t1-e1-mode in which the card combo would be running. For instance, selecting NTRX51FN automatically puts the cards in T1 mode of operation, while selecting the other PEC results in the cards running in E1 mode (proper PMC must be used for each mode). This is the mechanism employed by the user to change the operating mode of the cards (*see GUI screenshot Fig. 1*).

The addition of new hardware will add a new PEC **NTRX51TD** which the user can select. The new PMC card has the ability to function in either (T1 or E1) mode which is selectable through software (one PMC supports both modes). By default USP-Compact used to boot up with the NTRX51FN PEC

already provisioned which effectively set the card to T1 mode. However, with the introduction of the new PEC the default provisioned PEC is now NTRX51TD and the default t1-e1-mode is set to T1. This is now the default PEC whether running on new or old hardware and it's up to the user to match the PEC with the hardware that's being used. By selecting NTRX51TD PEC the t1-e1-mode becomes provisionable and at this point the user can select the mode he wants the cards to run in (*see GUI screenshot Fig. 2*).

Another minor change involves changing the PEC and/or port speed. In the old version of USP-Compact software *locking* the card was a sufficient prerequisite to make this modification. In the new version of the software the card must be taken *offline* before this provisioning will be allowed.

Figure 1 Fig. 1 Old hardware provisioning

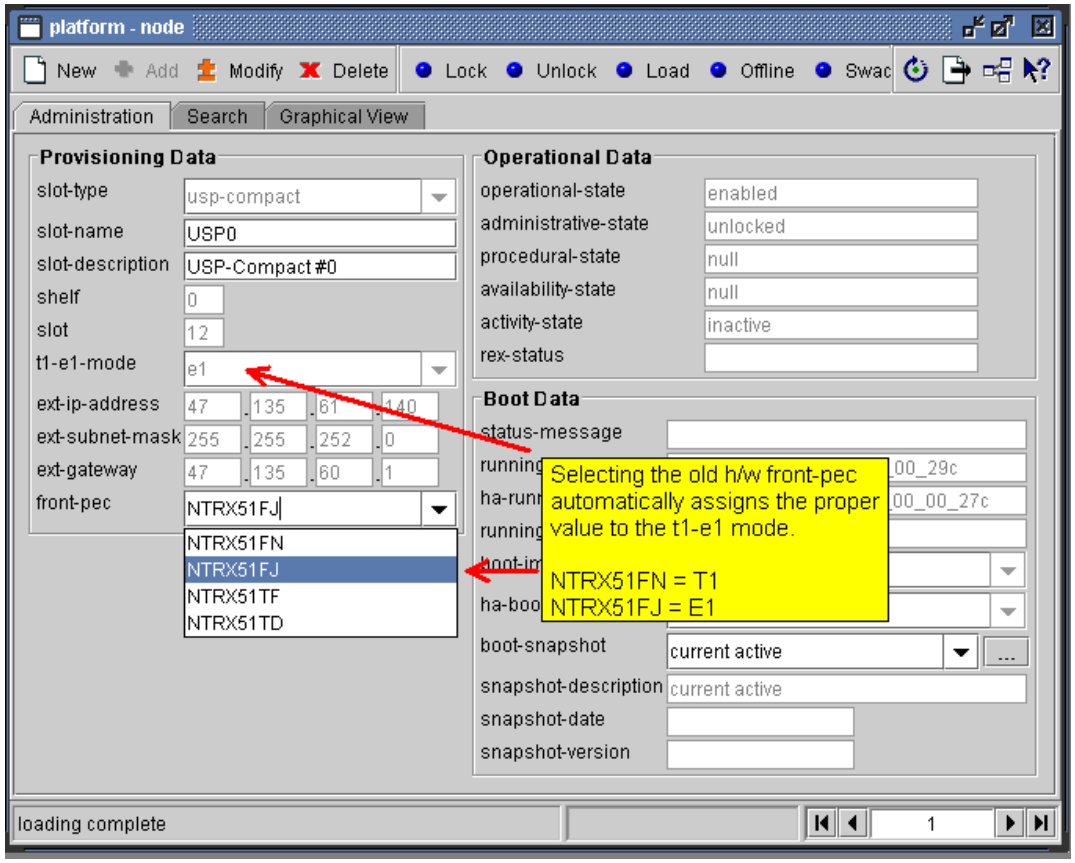


Figure 2 Fig. 2 New hardware provisioning

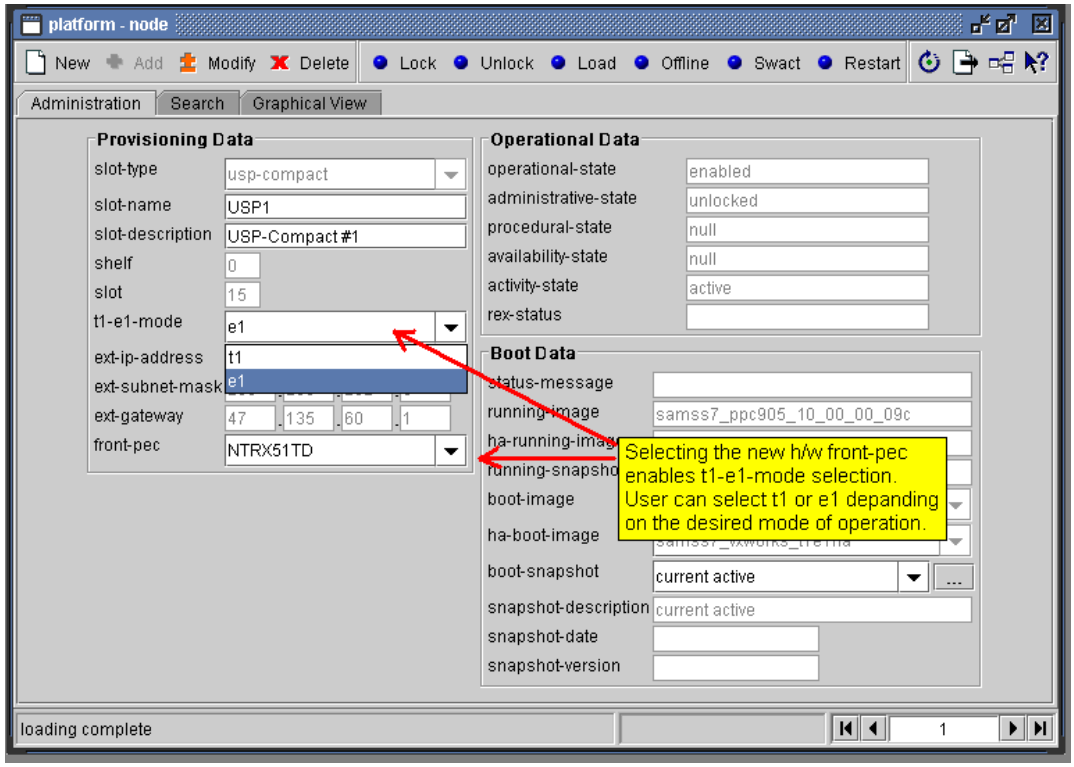


One other visible change introduced by this feature is that LED3 and LED4 are no longer present on the new hardware. On the old hardware LED3 would turn yellow whenever an alarm was received on the SS7 carrier port, but now LED1 takes that functionality and will turn yellow if this condition occurs. The condition normally indicated by LED4 on the old hardware is no longer an issue since the new hardware can handle it properly. Therefore LED4 is not longer needed and was removed.

34.4 Software Requirements or Dependencies

The SAM21 EM is used to provision bootup settings queried by USP-Compact at bootup time. EM is used to assign software loads to USP-Compact so that it knows what software to load when it boots up. This feature will result in a new USP-Compact software load. Therefore, when booting up USP-Compact on new hardware it is necessary to use the latest version of SAM21 EM application to be able to provisioning bootup information properly.

34.5 Limitations and restrictions

The main limitation is that base card and PMC software designed for the old hardware will only be able to run on that hardware. The same holds true for the software for the new hardware in that it will not function on the old hardware.

Also hardware mixing is not supported. This means that USP-Compact will run on either all old hardware or all new hardware. Only when upgrading hardware on USP-Compact both new and old hardware will be able to coexist for that short period of time.

34.6 Interactions

Not applicable.

34.7 Glossary

Term	Description
PMC	PCI Mezzanine Card
USPc	Universal Signaling Point - Compact
PEC	Product Engineering Code
SAM21 EM	SAM21 Element Manager

35: Functional Description (FN): A00009158

35.1 Feature name and Feature ID

Feature ID: A00009158
Feature name: M3UA over SCTP from Core to USP

35.2 Description

This activity implements M3UA RFC and SCTP RFC on CS2K core, supporting the following M3UA path type to USP.

- M3UA RFC over SCTP RFC client
- M3UA RFC over SCTP RFC server

This activity introduced changes on CS2K core but makes no changes to GWC platform.

This activity is based on the following specification on M3UA and RFC.

- RFC3332 Signaling System 7 (SS7) Message Transfer Part 3 (MTP3) - User Adaptation Layer (M3UA), September 2002
- M3UA Implementor's Guide, V7, February, 2004
- RFC2960 Stream Control Transmission Protocol, October 2000
- Stream Control Transmission Protocol (SCTP) Implementer's Guide, V12, October 15, 2004

Basically, without special mention, RFC2960 in this doc refers to the SCTP RFC2960 and SCTP Implementer’s Guide V12. RFC3332 in this doc refers to the M3UA RFC3332 and M3UA Implementor's Guide V7.

35.3 Support SCTP RFC on CS2K core

Activity A59023997 and A00003649 has implemented SCTP V5 [reference 6] on CS2K core. This activity will enhance the SCTP implementation based on SCTP RFC2960 [reference 3] and SCTP Implementer’s Guide V12 [reference 4].

35.3.1 SCTP chunk common header

In RFC2960, SCTP chunk common header is same as in SCTP V5. No change is introduced in this activity. Please refer to the following table for SCTP chunk common header format.

Table 1 SCTP chunk Common Header Format

Parameter	Type	Length(Octet)
Source Port Number	Mandatory	2
Destination Port Number	Mandatory	2
Verification Tag	Mandatory	4
Checksum	Mandatory	4

35.3.2 SCTP RFC chunks

This activity changes the following existing chunks to comply SCTP RFC version.

- SACK
- ABORT
- ERROR

This activity also adds a new chunk SHUTDOWN COMPLETE according to specification in RFC2960.

Other chunks are unchanged.

The following table shows the SCTP chunks supported by CS2K core. New and changed chunks are marked in BOLD.

Table 2 SCTP RFC chunks Supported by CS2K core

chunk Type	Value	chunk Explanation
DATA	0x0000	Payload Data
INIT	0x0001	Initiation
INIT ACK	0x0002	Initiation Acknowledgement
SACK	**0x0003**	**Selective Acknowledgement**
HEARTBEAT	0x0004	Heartbeat Request
HEARTBEAT ACK	0x0005	Heartbeat Acknowledgement

Table 2 SCTP RFC chunks Supported by CS2K core

chunk Type	Value	chunk Explanation
ABORT	**0x0006**	**Abort**
SHUTDOWN	0x0007	Shutdown Association
SHUTDOWN ACK	0x0008	Shutdown Acknowledgement
ERROR	**0x0009**	**Operation Error**
COOKIE ECHO	0x000A	State Cookie
COOKIE ACK	0x000B	Cookie Acknowledgement
SHUTDOWN COMPLETE	**0x000C**	**Shutdown Complete**

35.3.3 New and changed chunks

35.3.3.1 Selective Acknowledgement (SACK)

The chunk format of SACK is changed as below. Changed field is in BOLD.

Parameter	Type	Length(Octet)
Chunk Type	Mandatory	1
Chunk Flag	Mandatory	1
Chunk Length	Mandatory	2
Cumulative TSN Ack	Mandatory	4
Advertised Receiver Window Credit	Mandatory	4
Number of Gap Ack Blocks	Mandatory	2
Number of Duplicate TSNs	**Mandatory**	**2**
Gap Ack Block #1 - #N	Mandatory	n*4
Duplicate TSN 1-N	**Mandatory**	**n*4**

Two fields are introduced to this activity:

Number of Duplicate TSNs(16 bits): This field contains the number of duplicate TSNs the endpoint has received.

Duplicate TSN(32 bits): Every time a duplicate TSN is received before sending the SACK, it is added to the list of duplicates and appended to the end of the SACK. That is to say, if it is received n times(n>=1) before sending the SACK, it will be appended n-1 times. if it is received n times(n>=1) after sending the SACK for the TSN, it will be appended to SACK for current TSN n timers. The duplicate count is re-initialized to zero after sending each SACK.

35.3.3.2 Abort Association (ABORT)

The format of ABORT chunk is changed as below.

Parameter	Type	Length(Octet)
Chunk Type	Mandatory	1
Chunk Flag	**Mandatory**	**reserved (7 bits)** **T bit (1 bit)**
Chunk Length	Mandatory	2
zero or more Error Causes	Mandatory	4

When an endpoint is to close the association, ABORT chunk is sent with error causes.

The T bit is set to 0 if the sender filled in the Verification Tag expected by the peer. If the Verification Tag is reflected the T bit MUST be set to 1. Reflecting means that the sent Verification Tag is the same as the received one.

Refer to the following section for supported error codes on CS2K core.

35.3.3.3 Operation Error (ERROR)

An endpoint sends this chunk to its peer endpoint to notify it of certain error conditions. It contains one or more error causes. An Operation Error is not considered fatal in and of itself, but may be used with an ABORT chunk to report a fatal condition.

The below table shows the Cause Codes used in ERROR chunk, newly introduced Cause Codes are show in BOLD.

Cause Code	Cause	parameter of the Cause-specific Information	Description

1	Invalid Stream Identifier	Stream Identifier(16 bits) reserved (16 bits)	
2	Missing Mandatory Parameter	Number of missing parameters(32 bits) missing parameter type(16 bit)	
3	Stale Cookie Error	Measure of Staleness(32 bits)	
4	Out of Resource	None	
5	**Unresolvable Address**	**Unresolvable Address(32 bits)**	**Contains: complete Type, Length and Value of the address parameter. Indicates: the sender is not able to resolve the specified address parameter(e.g ,invalid transport address)**
6	**Unrecognized Chunk Type**	**Unrecognized Chunk(32 bits)**	**Contains: complete with Chunk Type, Chunk Flags and Chunk Length Indicates: the receiver does not understand the chunk (didn't defined)and the upper bits of the 'Chunk Type' are set to 01 or 11**
7	**Invalid Mandatory Parameter**	**None**	**Indicates: one of the mandatory parameters is set to a invalid value**
8	**Unrecognized Parameters**	**Unrecognized Parameters(32 bits)**	**Contains: contains unrecognized parameters copied from the INIT ACK chunk complete with TLV Indicates: returned to the originator of the INIT ACK chunk if the receiver does not recognize one or more Optional TLV parameters in the INITACK chunk.**
9	**No User Data**	**TSN value (32 bits)**	**Contains: the TSN of the DATA chunk received with no user data field Indicates: returned to the originator of a DATA chunk if a received DATA chunk has no user data**

10	**Cookie Received While Shutting Down**	**None**	**Indicates: A COOKIE ECHO was received while the endpoint was in SHUTDOWN-ACK-SENT state**
11	**Restart of an association with new addresses**	**New Address TLVs**	**Indicates: An INIT was received on an existing association. But the INIT added addresses to the association that were previously NOT part of the association. The New addresses are listed in the erro code.**
12	**User Initiated Abort**	**Upper Layer Abort Reason**	**Indicates: Upper Layer Abort Reason**
13	**Protocol Violation**	**Additional Information**	

35.3.3.4 Shutdown Complete (SHUTDOWN COMPLETE)

SHUTDOWN COMPLETE chunk is required to sent on reception of SHUTDOWN ACK at the completion of the shutdown process in SCTP RFC version. This activity introduced this new chunk type and supports related shutdown procedures.

The chunk format of new chunk SHUTDOWN COMPLETE is as below:

Parameter	Type	Length(Octet)
Chunk Type	**Mandatory**	**2**
Chunk Flag	**Mandatory**	**Reserved(7 bits)** **T bit (1 bit)**
Chunk Length	Mandatory	2

The T bit is set to 0 if the sender filled in the Verification Tag expected by the peer. If the Verification Tag is reflected the T bit MUST be set to 1. Reflecting means that the sent Verification Tag is the same as the received one.

35.3.4 Enhanced SCTP procedures

35.3.4.1 Normal Establishment of an Association

Association establishment procedures are modified to in RFC2960 section 5.1 comparing to SCTP v5. This activity enhances the existing SCTP implementation based on the specification in RFC2960 section 5.1.

35.3.4.2 Handle Duplicate or unexpected INIT, INIT ACK, COOKIE ECHO, and COOKIE ACK

New procedures are introduced to handle duplicate or unexpected INIT, INIT ACK, COOKIE ECHO, and COOKIE ACK in RFC2960 section 5.2. This activity enhances the existing SCTP implementation based on the specification in RFC2960 section 5.2.

The following scenarios are handled in this activity.

- Handle Duplicate INIT in COOKIE-WAIT or COOKIE-ECHOED States
- Unexpected INIT in States Other than CLOSED, COOKIE-ECHOED, COOKIE-WAIT and SHUTDOWN-ACK-SENT
- Unexpected INIT ACK
- Handle a COOKIE ECHO when a TCB exists
- Handle Duplicate COOKIE ACK

35.3.4.3 Path Verification

RFC2960 section 5.4 Path verification procedure is introduced to ensure all the address presented by the peer are in the fact belonging to the peer in SCTP implementor's guide V12. This activity enhances the existing SCTP implementation based on RFC2960 section 5.4.

35.3.4.4 User Data Transfer

User data transfer procedures are modified to enhance user data transfer reliability in RFC2960 section 6 comparing to SCTP V5. This activity enhances the existing SCTP implementation based on RFC2960 section 6.

35.3.4.5 Congestion Control

Congestion control procedures are modified in RFC2960 section 7 comparing to SCTP v5. This activity enhances the existing SCTP implementation based on RFC2960 section 7.

35.3.4.6 Fault Management

Fault management procedures are modified in RFC2960 section 8 comparing to SCTP v5. This activity enhances the existing SCTP implementation based on RFC2960 section 8.

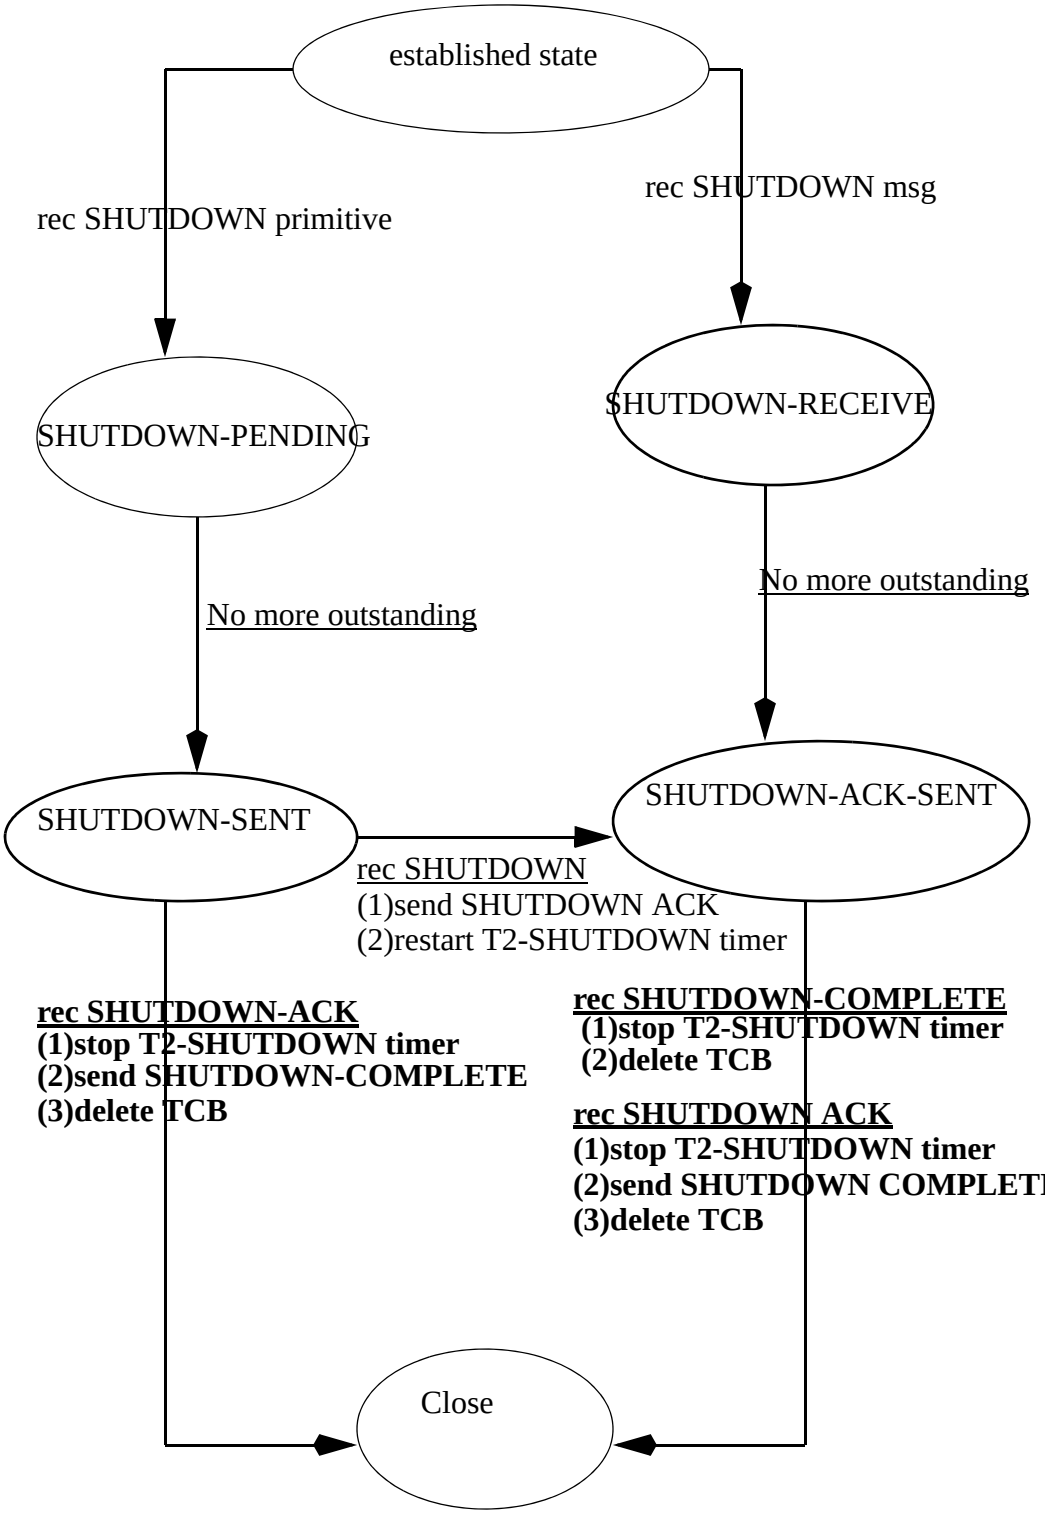
35.3.4.7 Abort of an Association

Association abort procedures are modified in RFC2960 section 9.1 comparing to SCTp V5. This activity enhances the existing SCTP implementation based on RFC2960 section 9.1.

35.3.4.8 Shutdown of an Association

SCTP RFC version has introduced new procedures to the termination of association (RFC2960 section 9.2). Refer to the following figure for the new procedures supported on CS2K core. The changes are marked in BOLD.

SCTP state diagram: termination of association



35.4 Support M3UA RFC on CS2K core

35.4.1 M3UA paths datafill

A new field PROTOCOL is added to table USPPATHS, to allow user to select the protocol of the path. The new field will have following 3 values:

- M3UA_V2_UDP - M3UA V2 over UDP
- M3UA_RFC_SCTP_CLIENT - M3UA RFC over SCTP CLIENT
- M3UA_RFC_SCTP_SERVER - M3UA RFC over SCTP SERVER

Normally, paths in the same pathset **SHOULD** be the same type. Warning message is displayed if customer try to datafill different path type in the pathset. But in-service cutover from M3UA V2 paths to M3UA RFC paths in one pathset is supported and Opposite cutover from M3UA RFC paths to M3UA V2 paths is not supported.

Please refer to section 2.4.11 and 2.4.12 for cutover and rollback procedures for M3UA V2 pathset to M3UA SCTP pathset.

The total message rate of all M3UA RFC paths over SCTP **SHOULD** be less than the max message rate that SCTP on core can support. Currently the max message rate that SCTP can support is 4500 msg/sec. Please refer to sction 2.4.10 and activity A00003649 “SCTP (Stream Control Transmission Protocol) Enhancements on XA-Core” for more detail.

One pathset on the CS2K core is configured as an ASP. IPSP configuration is not supported.

Refer to the following figure for datafill example of paths to USP.

Datafill example of M3UA paths to USP on CS2K core

Datafill for path to USP (M3UA V2 over UDP)
table usppaths
PATHNAME SRCPORT DESTIP DESTPORT PATHSEL **PATHPROT**
---
pathset_to_usp 0 4697 192 168 10 42 2905 0 **M3UA_V2_UDP**

Datafill for path to USP (M3UA RFC over SCTP client)
table usppaths
PATHNAME SRCPORT DESTIP DESTPORT PATHSEL **PATHPROT**
---
pathset_to_usp 0 4697 192 168 10 42 2905 0 **M3UA_RFC_SCTP_CLIENT**

Datafill for path to USP (M3UA RFC over SCTP server)
table pathset
PATHNAME SRCPORT DESTIP DESTPORT PATHSEL **PATHPROT**
---
pathset_to_usp 0 4697 192 168 10 42 2905 0 **M3UA_RFC_SCTP_SERVER**

As M3UA V2 path, the valid port number for M3UA RFC path is from 4697-4700 and 4710- 4721.

35.4.2 RFC M3UA message common header

Table 3 RFC M3UA message common header format

Field	Length (byte)	Description
Version	1 byte	it is set to 0x01, indicating M3UA release 1.0
Reserved	1 byte	it is set to 0x00
Message Group	1 byte	Refer to 2.4.3
Message Type	1 byte	Refer to 2.4.3
Message Length	4 byte	The Message Length defines the length of the message in octets, including the Common Header.

If version is not “0x01”, an ERROR message with error code “0x0001” is sent to USP.

35.4.3 RFC M3UA messages

"Table 4 M3UA RFC messages supported by CS2K" represents the set of messages that are required by M3UA RFC.

Table 4 RFC M3UA messages supported by CS2K

Message	Message Class and message type	Description
ERROR	0x0000	Error
NTFY	0x0001	Notify
DATA	0x0101	Payload data
DUNA	0x0201	Destination Unavailable
DAVA	0x0202	Destination Available
DAUD	0x0203	Destination State Audit
SCON	0x0204	Signalling Congestion
DUPU	0x0205	Destination User Part Unavailable
DRST	0x0206	Destination Restricted
ASPUP	0x0301	ASP Up
ASPDN	0x0302	ASP Down
ASPUP ACK	0x0304	ASP Up Acknowledgement
ASPDN ACK	0x0305	ASP Down Acknowledgement
ASPAC	0x0401	ASP Active
ASPIA	0x0402	ASP Inactive
ASPAC ACK	0x0403	ASP Active Acknowledgement
ASPIA ACK	0x0404	ASP Inactive Acknowledgement

If unsupported message class is received, ERROR message with error code 0x0003 is sent to USP.

If unsupported message type is received, ERROR message with error code 0x0004 is sent to USP.

Note: Since M3UA RFC is transported over SCTP, Heartbeat and Heartbeat ACK messages are not supported. SCTP has its own heartbeat mechanism to

detect loss of transport associations, Thus heartbeat procedure is not required when M3UA is transported over SCTP.

35.4.4 RFC M3UA Parameters

The following table represents the set of parameters that are required by RFC M3UA.

Table 5 RFC M3UA parameters supported by CS2K

Parameter	Parameter Id	Description
Traffic Mode Type	0x000b	Supported in ASP ACTIVE
Error Code	0x000c	Supported in ERROR
Status	0x000d	Supported in SCON
Affected Point Code	0x0012	Supported in DAVA, DUNA, DAUD, DRST, DUPU
Network Appearance	0x0200	Supported in SSNM messages and DATA message.
User/Cause	0x0204	Supported in DUPU
Congestion Indications	0x0205	Supported in SCON
Protocol Data	0x0210	Supported in DATA

When an optional parameter is received and not supported, the message is processed but the optional parameter is discarded silently.

35.4.5 RFC M3UA message format

35.4.5.1 ASPSM messages

No optional parameter is supported in the following messages.

ASP UP

ASP DOWN

ASP UP ACK

ASP DOWN ACK

35.4.5.2 ASPTM messages

The message format of ASP ACTIVE is as below:

Parameter	Type	Length (byte)

Traffic Mode Type	Optional	Tag(2 bytes) Length(2 bytes) Traffic Mode Type (4 bytes) 0x0001 - Override

If unsupported traffic mode type is received, ERROR message is sent to peer.

No optional message is supported in the following message.

ASP INACTIVE

ASP ACTIVE ACK

ASP INACTIVE ACK

35.4.5.3 SSNM messages

Message format for DAVA, DUNV, DRST and DAUD is as below.

Parameter	Type	Fields
Network Appearance	Optional	Tag(2 bytes) Length(2 bytes) Value(4 bytes)
Affected Point Code	Mandatory	Tag(2 bytes) Length(2 bytes) Mask 1 (1 bytes) Affected PC 1 (3 bytes) ..... Mask n (1 bytes) Affected PC n (3 bytes)

Message format for SCON is as below:

Parameter	Type	Fields
Network Appearance	Optional	Tag(2 bytes) Length(2 bytes) Value(4 bytes)
Affected Point Code	Mandatory	Tag(2 bytes) Length(2 bytes) Mask 1 (1 byte) Affected PC 1 (3 bytes) ..... Mask n (1 byte) Affected PC n (3 bytes)

Congestion Indications	Optional	Tag (2 bytes) Length (2 bytes) Reserved (3 bytes) Cong Level (1 byte)

Message format for DUPU is as below.

Parameter	Type	Fields
Network Appearance	Optional	Tag(2 bytes) Length(2 bytes) Value(4 bytes)
Affected Point Code	Mandatory	Tag(2 bytes) Length(2 bytes) Mask 1 (1 byte) Affected PC 1 (3 bytes) ..... Mask n (1 byte) Affected PC n (3 bytes)
User/Cause	Mandatory	Tag (2 bytes) Length (2 bytes) Cause (2 bytes) User (2 bytes)

35.4.5.4 DATA message

Message format for DATA is as below.

Parameter	Type	Fields
Network Appearance	Optional	Tag(2 bytes) Length(2 bytes) Value(4 bytes)
Protocol Data	Mandatory	Tag(2 bytes) Length(2 bytes) Protocol Data (variable length)

35.4.5.5 Error Message

Message format for Error is as below.

Parameter	Type	Fields

Error Code	Mandatory	Tag (2 bytes) Length (2 bytes) Error code (4 bytes)

Error Code supported by CS2K is as below.

Error Code	Description
0x01	Invalid Version
0x03	Unsupported Message Class
0x04	Unsupported Message Type
0x06	Unexpected Message
0x09	Invalid Stream Identifier
0x11	Invalid Parameter Value
0x12	Parameter Field Error
0x13	Unexpected Parameter
0x16	Missing Parameter

35.4.5.6 Notify Message

The Notify message used to provide an autonomous indication of M3UA events in USP to the CS2K.

Message format for Notify message is as below.

Parameter	Type	Fields
Status	Mandatory	Tag (4 bytes) Length (4 bytes) Status Type and Status Information (8 bytes) 0x0101 - Application Server State Change, inactive 0x0102 - Application Server State Change, active 0x0103 - Application Server State Change, pending

Notify message with unsupported status type and status information received is discarded silently.

35.4.6 RFC M3UA procedures

This activity implements the M3UA layer procedures based on the RFC3332 section 4.3, 4.5, 4.6.

35.4.6.1 Activate USP paths

Users can activate USP paths via ACT command in MAPCI CCS7 directory. If the path is the first activated path in the pathset, ASP UP and ASP ACTIVE procedure is started. The path is set to INSV after receive NTFY (AS ACTIVE) from USP. If the path is not the first activated path in the pathset, ASP UP and ASP ACTIVE procedure is not started. The path is set to INSV after SCTP association is established.

Refer to the following two figures for the message flow of activating USP path in pathset over SCTP.

Figure 1 Activate first path in the pathset when both paths are OFFL

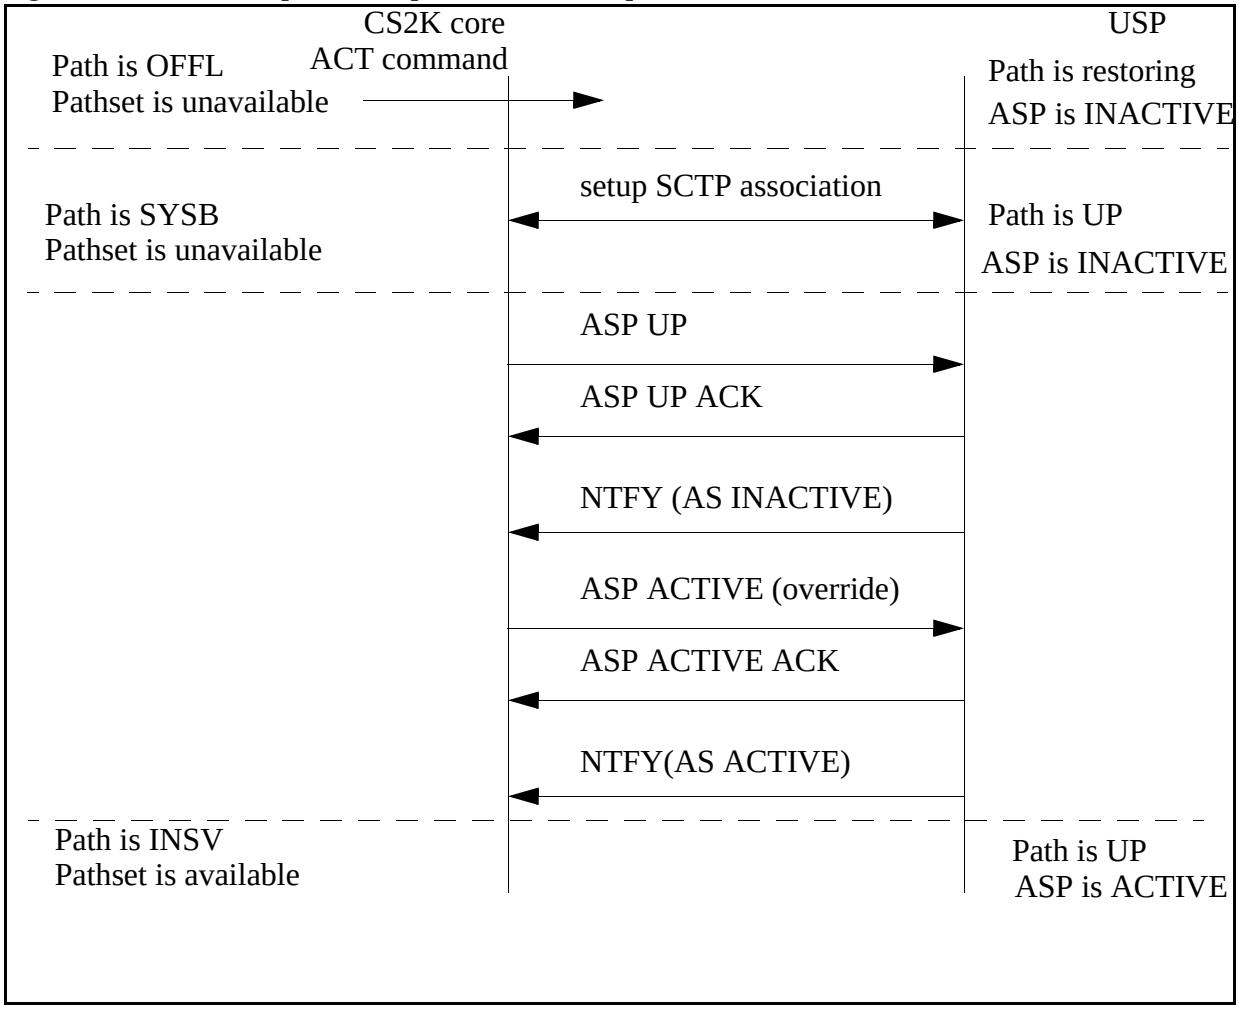


Figure 2 Activate other paths in the pathset when one of the paths is INSV

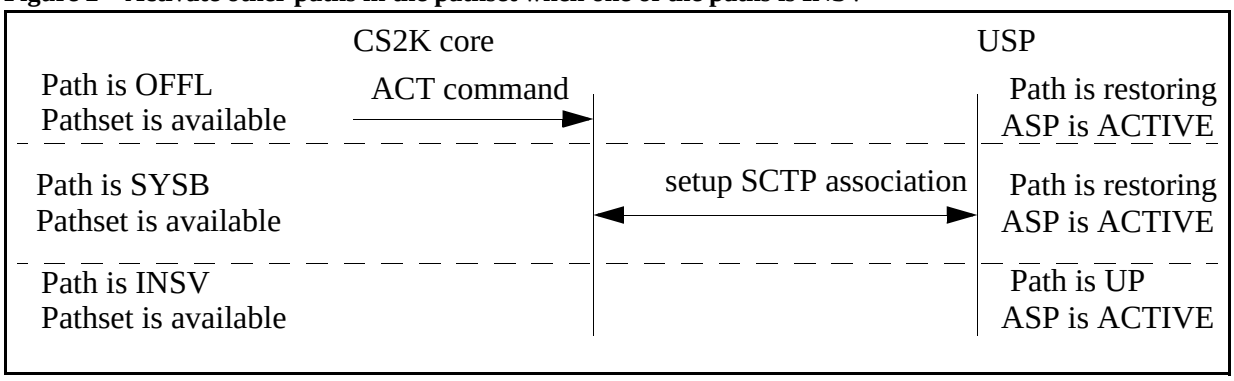

35.4.6.2 Deactivate M3UA path

Users can deactivate USP paths via DEACT command in MAPCI CCS7 directory. The path is set to OFFL when it is deactivated.

- Deactivate the last INSV path in the pathset

If the path is the last INSV path in the pathset, ASP INACTIVE and ASP DOWN procedure is started. and then the SCTP association is taken down.

After the path is deactivated, there is no more INSV path available. No more outgoing and incoming traffic is allowed immediately. ASPIA and ASPDN is sent to peer to update the ASP status.

In this case, the traffic received from peer ULP before ASPIA is received are discarded because no more outgoing and incoming traffic is allowed after the pathset is down.

- Deactivate INSV path (not the last INSV path in the pathset)

If the path is not the last INSV path in the pathset, ASP INACTIVE and ASP DOWN procedure is not started. SCTP association is taken down immediately.

After the path is deactivated, the path can not send outgoing traffic any more. SCTP SHUTDOWN chunk is sent to peer to take down the SCTP association.On reception of the SHUTDOWN chunk in the peer side, the traffic received from peer ULP before SHUTDOWN arrived are still sent out to the Core. To avoid traffic lost, the path will accept these incoming traffic and report to ULP.

- Deactivate SYSB path

If the path is in SYSB, if SCTP association is established, send SHUTDOWN to shutdown the association, otherwise, send ABORT to abort establishing SCTP association.

Please refer to the following three figures for the message flow of deactivating USP path in pathset over SCTP.

Figure 3 Deactivate a path in pathset if it is not last INSV path

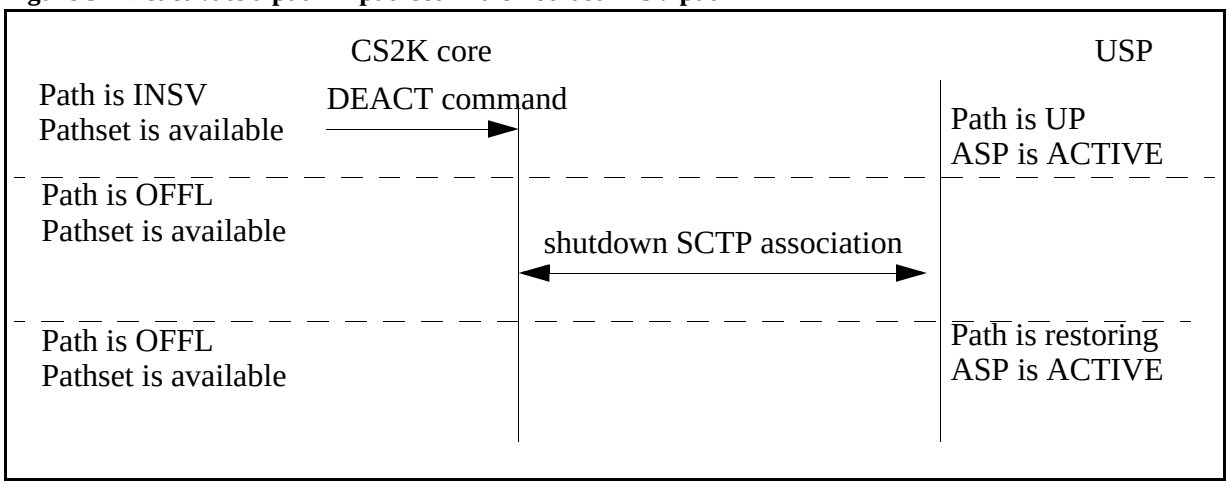

Figure 4 Deactive the last INSV path in the pathset

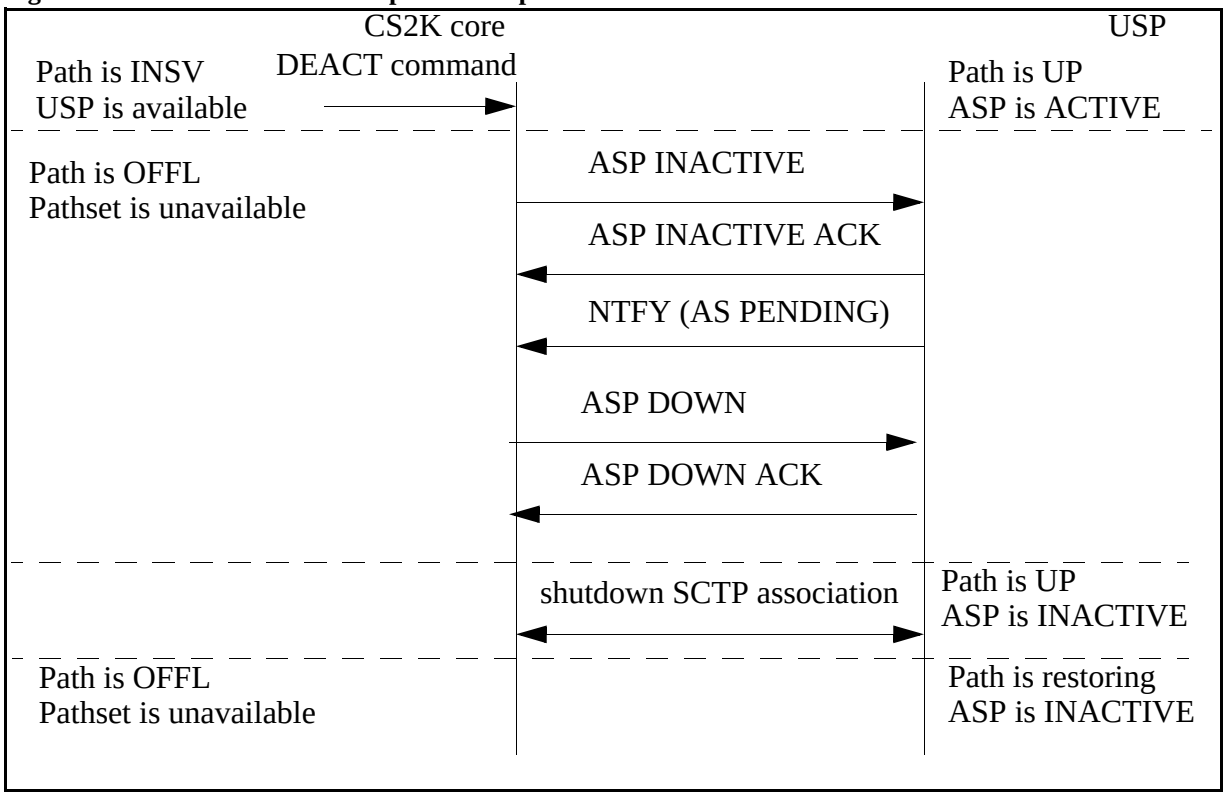

Figure 5 Deactivate a SYSB path if SCTP association is established

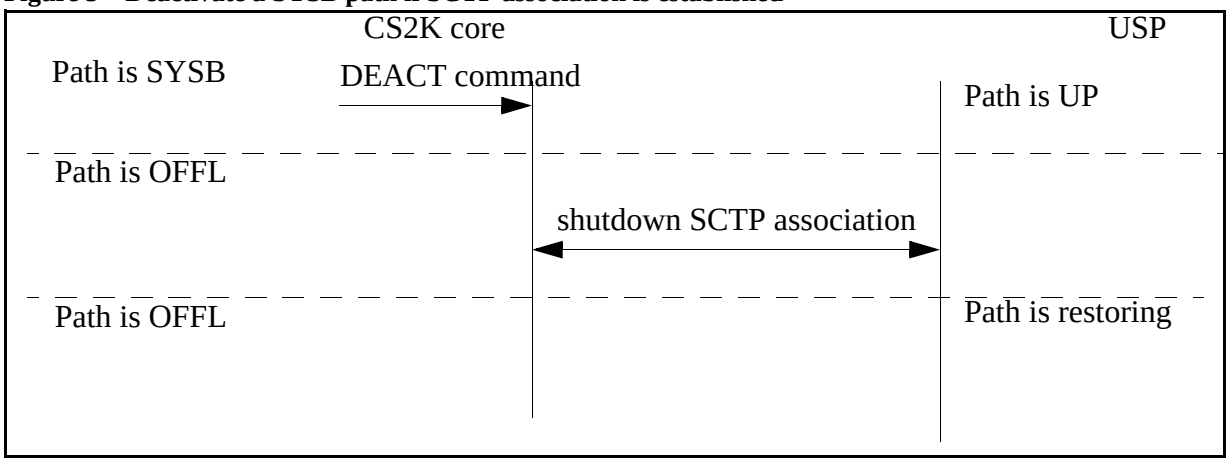

Figure 6 Deactivate a SYSB path if SCTP association is not established

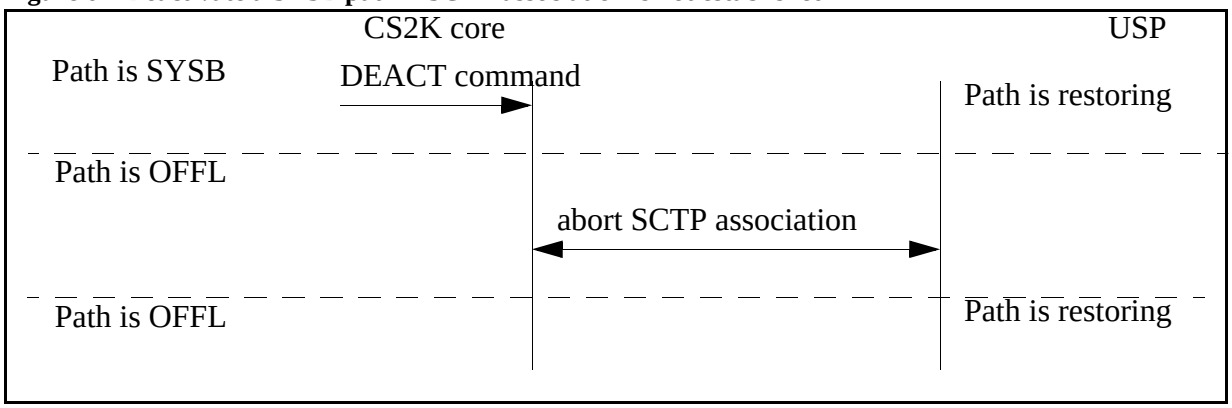


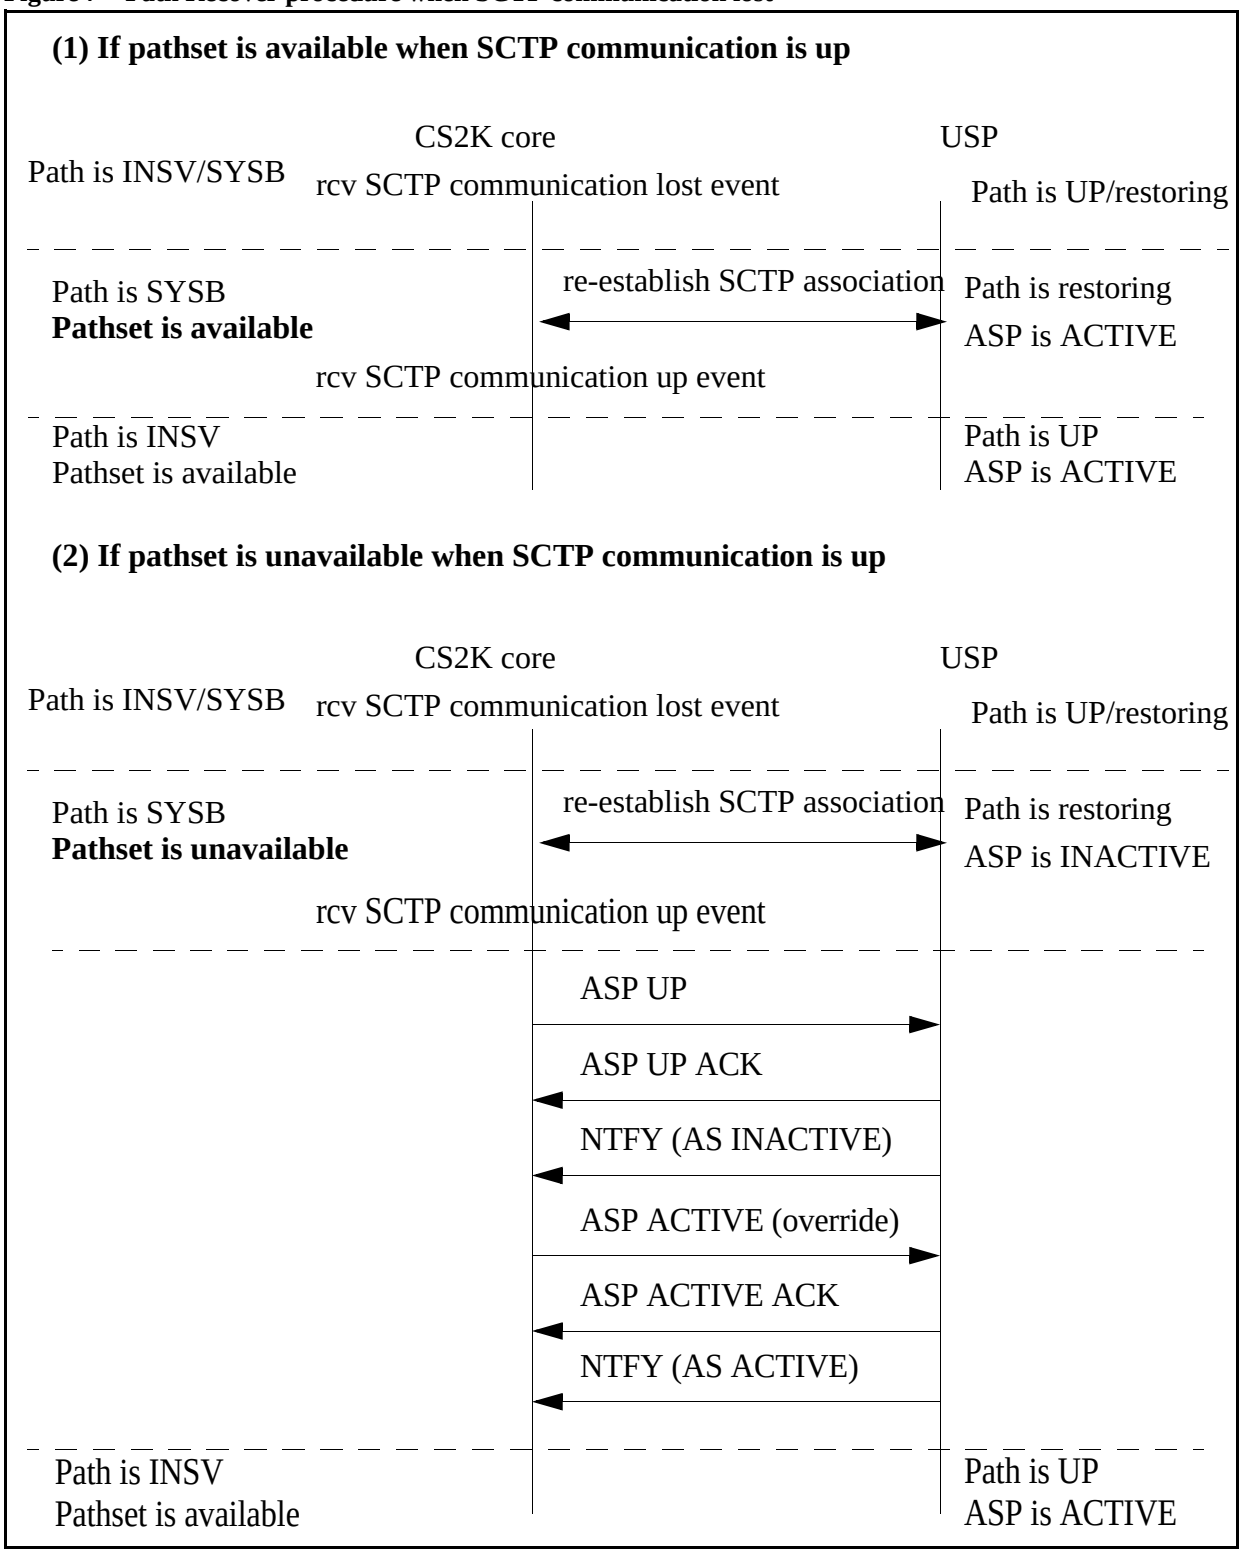
35.4.6.3 SCTP communication lost recovery

On reception of SCTP communication lost notify, M3UA management shall request the SCTP transport layer to re-establish the SCTP association.

If the pathset is unavailable when the SCTP communication is up, ASP UP and ASP ACTIVE procedure is started, otherwise, set the path to INSV.

Refer to the following figure for message flow of SCTP communication lost recovery.

Figure 7 Path Recover procedure when SCTP communication lost



35.4.6.4 SCTP congestion handling

Receiving SCTP STATUS CHANGE notification with congestion enter indication from one path in the pathset indicates that other paths in the pathset have the same situation because the paths are load sharing.

On reception of first path congestion indication, the pathset is regarded as congestion, M3UA layer notify the routeset management to update the status of the routeset related with pathset. The routeset status is updated as if received a SCON from USP. When all of the paths are out of congestion, the routeset management is notified. The routeset status related with the pathset is updated as if received a DAVA from USP.

35.4.6.5 SCTP stream mapping

M3UA RFC supports 2 outgoing SCTP streams.

- M3UA DATA message is sent over SCTP stream 1.
- ASPSM, MGMT messages are sent over SCTP stream 0.
- SSNM, ASPTM, BEAT ACK are sent over SCTP stream 0.

If the remote peer can not support 2 incoming streams, M3UA should take down the association.

35.4.6.6 Notify handling procedure

When receiving a Notify message reflecting a change in the AS state from USP, the CS2K core updates the local USP status and restart the ASP UP procedure if necessary. Please refer to the table below for Notify handling on CS2K core.

Table 6 Notify handling

Notify message	Status of paths	Action
AS ACTIVE	At least one path is INSV	No furthur action is taken.
AS ACTIVE	No path is INSV	Set the non OFFL paths to SYSB and start path activation procedure and sent out ASP UP message.
AS INACTIVE	In all cases	Set the non OFFL paths to SYSB and start path activation procedure and sent out ASP UP message.
AS PENDING	In all cases	Set the non OFFL paths to SYSB and start the path activation procedure and sent out ASP UP message

35.4.6.7 SSNM message handling procedure

DAUD is sent to USP periodly to audit the status of routesets. When the CS2K core receives DAVA, DUNA, SCON, application level is notified.

When the CS2K core receives DRST, application level is notified as if DAVA is received.

Please refer to activity A00009165-Offline Routesets w/o Alarms for more information on SSNM handling when the routeset is not activated on USP and Core.

35.4.7 M3UA RFC message extension

The PROVISIONING messages and MSC_UPDATE messages, which used as M3UA V2 extension on CS2K core to support communication between CS2K core and USP, will be used unchanged as M3UA RFC extension on CS2K core to support communication between core and USP.

35.4.8 Peg OM for M3UA RFC

The existing M3UA OMs are supported for M3UA RFC.

- TXMSG
- RXMSG
- LOSTMSG

M3UA RFC and M3UA V2 use the same OM counters.

35.4.9 M3UA timers for M3UA RFC

- ASPUP timer

When the status of pathset is changed from SYSB to INSV, ASPUP is sent to USP. ASPUP is resent to USP every 2s utill ASPUP ACK is received from USP.

- ASPAC timer

After received ASPUP ACK from USP, ASPAC is sent to USP. ASPAC is resent every 2s utill ASPAC ACK is received from USP.

- ASPIA timer

When the status of pathset is changed from INSV to SYSB or OFFL, ASPIA is sent to USP. ASPIA is sent for only once. If ASPIA ACK is not received from USP, the ASPIA is not sent again. ASPDN is sent out after ASPIA timer timeout.

- ASPDN timer

After received ASPIA ACK from USP or ASPIA timer timeout, ASPDN is sent to USP. ASPDN is sent for only once. If ASPDN ACK is not received from USP, the ASPDN is not sent again. SCTP association is taken down after ASPDN timer timeout.

35.4.10 Max message rate supported

The message rate that one M3UA RFC path can support is up to 1500 msg/sec.

The total message rate of all M3UA RFC paths over SCTP **SHOULD** be less than the max message rate that SCTP on core can support. Currently the max message rate that SCTP can support is 4500 msg/sec. Please refer to activity A00003649 “SCTP (Stream Control Transmission Protocol) Enhancements on XA-Core” for more detail.

35.4.11 Cutover from M3UA V2 pathset to M3UA SCTP pathset

This cutover procedure is used to change the in-service M3UA V2 pathset to M3UA SCTP pathset. This cutover MUST be done with low traffic.

1. Make sure at least **two** paths are provisioned in the M3UA V2 pathset. All of the paths are INSV.

2. Deactivate one of the M3UA_V2_UDP path in the pathset. The status of the path is OFFL now.

3. Change the pathprot from M3UA_V2_UDP to M3UA_RFC_SCTP_*. The pathprot M3UA_RFC_SCTP_* could be M3UA_RFC_SCTP_CLIENT or M3UA_RFC_SCTP_SERVER.

4. Activate the path in MAPCI. Verify the status of the path is INSV now and traffic are sent to the path.

5. Soak for some time. The time depends on customer’s decision.

6. Repeat step 2-5 for other M3UA_V2_UDP paths in the pathset.

Note: it is not recommended provisioning different type paths in one pathset. The cutover status should be regarded as a transient status. During cutover, there is no traffic change over between paths, which will cause traffic lost when the path is being deactivated.

35.4.12 Rollback from M3UA SCTP pathset to M3UA V2 pathset

This rollback procedure is used to restore the paths to M3UA_V2_UDP paths in case any problem during cutover.

1. Deactivate one of the M3UA_RFC_SCTP_* path in the pathset. The status of the path is OFFL now.

2. Change the pathprot from M3UA_RFC_SCTP_* to M3UA_V2_UDP. The pathprot M3UA_RFC_SCTP_* could be M3UA_RFC_SCTP_CLIENT or M3UA_RFC_SCTP_SERVER.

3. Activate the path in MAPCI. Verify the status of the path is INSV now and traffic are sent to the path.

4. Repeat step 1-3 for other M3UA_RFC_SCTP_* paths in the pathset.

Note: it is not recommended provisioning different type paths in one pathset. The cutover status should be regarded as a transient status. During cutover, there is no traffic change over between paths, which will cause traffic lost when one path is being deactivated.

35.5 Hardware Requirements or Dependencies

NA

35.6 Software Requirements or Dependencies

NA

35.7 Limitations and restrictions

1. This activity implements a basic functionality of M3UA RFC on CS2K core. Only those functionalities mentioned in this document are commited by this activity.

2. This activity doesn’t support dynamic register procedure (RFC3332 section 4.4) on CS2K core.

3. There is no changes introduced in the Core swact mechanism for SCTP and M3UA connections. The existing behavior is expected during SWACT after this activity.

4. There is no changes introduced into the path load sharing mechanism. The existing behavior is expected after this activity.

5. When the path is datafilled as SCTP server, the port used to listen for INIT chunk is not 2905, it can be from 4697-4700 to 4710-4721.

6. It is not recommended provisioning different type paths in one pathset. The cutover status should be regarded as a transient status.

7. There is no traffic change over between paths, which will cause traffic lost when one path is being deactivated.

8. SCTP CRC32 checksum is not supported in Core. Adler checksum should be used to establish SCTP association.

36: Functional Description (FN): A00009173

36.1 Feature name and Feature ID

A00009173: Linux <-> SOS Messaging

36.2 Description

1. Define a Linux CA process <-> SOS messaging framework that is data generic, fast, reliable, and expandable. Provide tools to verify correct operating behavior.
2. Convert existing ApplMan/APPLSOS HPTLI user to use the framework, in order to improve robustness and reduce HPTLI IO class process realtime used.

This feature includes a Compact Call Agent (CCA) and Siren Call Agent (SCA) phase. The SCA phase provides additional capabilities including:

1. TIPC support
2. Multiple service support
3. Siren Availability Management Framework (AMF) support

Functionality is always enabled, and cannot be disabled.
Password protected CI (SOS2CACI) is intended for designer/GNPS purposes only.

36.3 Hardware Requirements or Dependencies

No new H/W dependencies.
CCA phase runs on the CompactPCI hardware.
SCA phase runs on Siren/ATCA hardware.

36.4 Software Requirements or Dependencies

CCA phase delivers on NCGL8/SN09 release lineup.
SCA phase delivers on NCGL9/SN10 release lineup.

For lab purposes, NCGLx is coded to support earlier SOS image releases in addition to the intended lineups described above.

36.5 Limitations and restrictions

No limitations or restrictions visible to the user - it is an internal feature.

36.6 Interactions

No interactions with existing features.

37: Functional Description (FN): A00009182

37.1 Feature name and Feature ID

Nortel Carrier Grade Linux Persistent Memory Application Programming Interface.

37.2 Description

This feature will create a unified API to access all persistent memory in NCGL products. The API will exist in the kernel and will be exported to user space through a new persistent memory driver. Persistent memory users in the kernel and in user space in all products which have persistent memory will be updated to use the new API.

There are three methods for writing to persistent memory which are being supported. The first method, mmapping, is only used by user space applications. This allows any user space application to request a chunk of persistent memory and then write to it as if the memory was obtained through a malloc request. Users of this method include DSSAVE, VFOOT and the Neptune Persistent Memory API.

The second method is through a write request. When a user wants to write to persistent memory they will issue a write request. The API will then update persistent memory with the data according to the options configured during registration. Some of these options include writing to the active buffer, writing to per-cpu buffers, or writing fixed size logs. Users of this method include kernel fault handling, sanity timers, bigfoot, etc.

The final method is only available to the kernel. The kernel users will register a special handle with the API. The special handle contains pointers describing the region. The API will update the handle with the location of the desired region in persistent memory and store a pointer to the handle. Then the user can use the pointers in the handle to write logs. Since the API has a pointer to the handle, it is able to update the pointers when a rotation occurs. This method is being provided for users that need to be extremely fast and cannot wait on a spinlock for data synchronization. Users of this method include kernel scheduler history and kernel exception history.

The memory is divided up into user defined partitions, which may be divided further depending on the user specifications. If the user specifies one or more

blocks then the partition data is divided evenly into blocks. Only one block is written to at any given time and is considered active. Users can provision regions within the blocks to store data for a particular application. Each region exists at the same location in all blocks.

API users will be able to provision the following attributes for log regions:
- Fixed or variable size logs
- Separate logs areas for each processor or a single area (variable size logs must have a single area)

The API will provide the following functionality to the user:
- Register a partition: Reserve a section of persitent memory
- Register a log region: Reserve a section of a block in a partition
- Rotate a partition: Make an inactive block active
- Lock a block: Take block out of rotation
- Unlock a block: Allow block to be in rotation
- Read data: Read data from persistent memory
- Write log or data: Write a log or data to persistent memory
- Mmap memory: Mmap a section of memory to userspace
- Seek to location: Set the offset for reading
- Set reset flag: Reset persistent memory on next reboot

In order to use persistent memory, the user will have to register a partition with a unique partition string identifier. If the partition will be used for logs then the user will also have to register a region within the partition. Then the user will be able to use one of the three methods described above to begin writing to persistent memory.

In order to detect corruption, all element headers in persistent memory will have checksums. These checksums will only be validated during initialization.

During an upgrade from a release that does not support the API, the API will detect that the memory format is incorrect and will re-initialize persistent memory. Subsequent upgrades will not need to re-initialize persistent memory unless the format of peristent memory changes.

The persistent memory device driver will export the kernel API to userspace. It will keep track of any open handles for a user session and create buffers for copying data to and from userspace during reading and writing. When userspace wants to interact with persistent memory, they will have to open the persistent memory device, issue an IOCTL to set the area that they are interested in and then write or mmap to the device. The following is a list of file operations that are supported by the driver:
- read
- write
- ioctl

- mmap
- seek
- open
- release

The following is a list of persistent memory driver IOCTLs and their arguments:

- PMEMSETCB: Setup the device to perform operations on the control block
  No arguments
- PMEMSETPART: Setup the device to perform operations on a partition
  ```
  struct pmem_set_part
  {
     char desc[32];      // Partition string id
  };
  ```
- PMEMSETBLK: Setup the device to perform operations on a block. Device must be set to a partition.
  ```
  struct pmem_set_block
  {
     __s8;      // Block id
  };
  ```
- PMEMSETREG: Setup the device to perform operations on a region. Device must be set to a partition.
  ```
  struct pmem_set_region
  {
     char desc[32];      // Region string id
     __u8 block_id;
  };
  ```
- PMEMSETSHADOW: Setup the device to perform operations on the shadow copy of persistent memory.
  No arguments
- PMEMCLRSHADOW: Clear the shadow copy of persistent memory
  No arguments
- PMEMREGPART: Register a partition
  ```
  struct pmem_reg_log_part
  {
     char desc[32];         // Partition string id
     __u32 size;            // Size of partition data
     __u16 num_blocks; // Number of blocks in partition. 0 for mmap
     __u8 version;          // Version of partition
  };
  ```
- PMEMREGLOGREGION: Register a log region. Device must be set to a partition.
  ```
  struct pmem_reg_region
  {
  ```

```
    char desc[32];      // Region string id
    __u32 size;         // Size of region data
    __u32 flags;        // See below for flags
    __u32 fixed_size;  // Size of fixed size logs. 0 for variable size logs
   __u16 num_log_desc; // Number of variable size logs descriptors.
    __u8 version;       // Version of region
    __u8 block_id;      // Block id for resulting region handle.
};
```

PMEM_REGION_FLAG_PERPROC: Specifies that each processor writes to its own area in the region. Only valid for fixed size logs. PMEM_REGION_FLAG_STOP_FULL: Specifies that persistent memory will stop writing when the logs are full. Only valid for fixed size logs.

- PMEMROTATE: Rotate a log partition. Device must be set to a log partition.

```
__u8 lock;     // 0 to leave block unlocked, 1 to lock old block.
```

- PMEMLOCKBLK: Lock a log block. Device must be set to a block.

  No arguments
- PMEMUNLOCKBLK: Unlock a log block. Device must be set to a block.

  No arguments
- PMEMSETRESET: Sets the control block reset flag. Device must be set to the control block.

  No arguments
- PMEMCLRRESET: Clears the control block reset flag. Device must be set to the control block.

  No arguments
- PMEMGETCBINFO: Retrieves control block data. Device must be set to the control block.

```
struct pmem_cb_info
{
   __u32 size;
   __u32 avail_mem;
   __u16 num_partitions;
};
```

- PMEMGETPARTINFO: Retrieves partition data. Device must be set to a partition.

```
struct pmem_part_info
{
   __u32 size;
   __u32 avail_mem;
   __u16 num_blocks;
   __u16 num_regions;
};
```

In order to get logs, the user will have to decode the log structures in the region data. These structures contain the log data, as well as some information that

was obtained when the log was generated such as the timestamp and a log checksum. The structures are different for fixed size logs and variable size logs. The fixed size logs contain a small header for each cpu (or just one header if the logs are not per-proccessor), which describe the boundaries of the log area. Logs are then located one after the other.

The variable size log structures contain an array of log descriptors which describe the individual logs. Each log descriptor contains a time stamp, a checksum of the log data and the location of the log data in the region.

Table 1 Log Region Data With Log Descriptors Structure

Element	Type	Description
Region Description	char x[32]	Identifier for region
Last index	__u16	Index of last valid log
Current index	__u16	Index of current log
Checksum	__u32	Checksum of index information
Log 0 Offset	__u32	Offset of log from start of region data
Log 0 Size	__u32	Size of log data
Log 0 Time stamp	__u64	Time of log
Log 0 Log checksum	__u32	Checksum of log data
Log 0 Checksum	__u32	Checksum of log header data
...		
Log X Offset	__u32	Offset of log from start of region data
Log X Size	__u32	Size of log data
Log X Time stamp	__u64	Time of log
Log X Log checksum	__u32	Checksum of log data
Log X Checksum	__u32	Checksum of log header data
Log 0 data	raw	Log data
...	raw	Log data
Log X data	raw	Log data

Table 2 Log Region Data Without Log Descriptors Structure

Element	Type	Description
Region Description	char x[32]	Identifier for region
CPU 0 start offset	__u32	Offset of start of per cpu region from start of region
CPU 0 end offset	__u32	Offset of end of per cpu region from start of region
CPU 0 current offset	__u32	Offset from the start of the region to the current log
CPU 0 logs lost	__u32	Number of logs lost
...		Per cpu information
CPU X start offset	__u32	Offset of start of per cpu region from start of region
CPU X end offset	__u32	Offset of end of per cpu region from start of region
CPU X current offset	__u32	Offset from the start of the region to the current log
CPU X logs lost	__u32	Number of logs lost
CPU 0 Log record 0	struct	Log data
...	struct	Log data
CPU 0 Log record Y	struct	Log data
...	struct	Log data
CPU X Log record 0	struct	Log data
...	struct	Log data
CPU X Log record Y	struct	Log data

All users of persistent memory in the kernel and in userspace will be updated to use the new API. In the kernel this includes:

- Scheduler history
- Exception history
- Fault handling

- Sanity timers
- Persistent panic

In userspace this includes:
- DSSAVE
- VFOOT
- Neptune persistent memory API
- bigfoot
- bigfootd

A new userspace application will be created to manage persistent memory. This program will have the following features:
- Read persistent memory from a file or from the device driver
- Dump persistent memory to a file
- Read and decode all header information
- Read and decode any of the NCGL logging regions
- Lock or unlock a block
- Rotate a partition
- Set or clear the reset bit in the control block
- Read and clear the shadow copy of persistent memory

A program will be created to create backup copies of persistent memory on bootup. The program will check if a shadow copy of persistent memory exists and if so then it will copy the shadow copy to disk. If not then it will copy the entire persistent memory to disk instead. The last five copies of persistent memory will be maintained on disk.

37.3 Hardware Requirements or Dependencies

There are no new hardware requirements being introduced by this feature.

37.4 Software Requirements or Dependencies

There are no new software requirements being introduced by this feature.

37.5 Limitations and restrictions

This feature has the following limitations:
- The total size of persistent memory must be less than 4 GB
- All string identifiers must be less than 32 characters
- The maximum number of partitions is 32
- The maximum number of buffers in a log partition is 32
- The maximum number of regions in a log partition is 32
- The maximum number of variable size logs in a region is 65535
- Intel and MIPS64 architectures are not supported in this release

37.6 Interactions

This feature interacts with the following areas:

- Kernel scheduler history: This will be updated to use the new API for reading and writing logs.
- Kernel exception history: This will be updated to use the new API for reading and writing logs.
- Kernel fault handling: In addition to notifying hwmon that a fault has occurred, fault handling will now write logs to persistent memory.
- Kernel sanity timers: In addition to notifying hwmon that a sanity timeout has occurred, sanity timeout code will now write logs to persistent memory, and will rotate the log partition if a board reset is required.
- Kernel persistent panic: The panic code will no longer attempt to store scheduler and exception information in persistent memory.
- Bigfoot: This will use the new persistent memory driver to read logs from bigfoot.
- bigfootd: This will use the persistent memory driver to retreive bigfoot information. It will no longer initialize persistent memory with the bigfoot driver.
- DSSAVE: This will use the persistent memory driver to mmap memory instead of the dssave driver.
- VFOOT: This will use the persistent memory driver to mmap memory instead of the bigfoot driver.
- Neptune Persistent Memory API: This will use the persistent memory driver to mmap memory instead of the bigfoot driver.
- hwmon: This will no longer attempt to write logs to persistent memory when a sanity timeout or a fault occurs.

37.7 Glossary

Term	Description
New term	Definition

38: Functional Description (FN): A00009189

38.1 Feature name and Feature ID

A00009189 SESM support for 64 character FQDN. Related feature: A00008043 CS2K Support for 64 Character FQDN

38.2 Description

This feature makes enhancements on SESM & CS2K to make the whole system fully support Gateway FQDN up to 64 characters.

In SN07/SN08, FQDN support was introduced into CS2K system. But the solution had a number of limitations. The size of the gateway FQDN and domain name were restricted. Only a single domain name was supported per GWC, and only the hostnames were used in the CS2K-MT GUI, OSSGATE, TMM, and LMM.

This SN09 feature is intended to remove those limitations while still maintaining backwards compatibility:

- Multiple gateway domain names are supported per GWC as part of the Gateway Name field as long as default gateway domain name is not provisioned on the GWC. In this case, the Gateway Name represents a gateway FQDN and can be up to 64 characters.
- Only one default gateway domain name (up to 62 characters) can be provisioned per GWC. If provisioned, then the Gateway Name represents the gateway hostname. The FQDN is the concatenation of the Gateway Name and the default domain name, which together can contain up to 64 characters.
- The customer can use the Gateway Name as a hostname or a FQDN in CS2K-MT GUI, OSSGate (excepts SERVORD+ commands), TMM and LMM.
- When GWC has default gateway domain name provisioned, you must use only the gateway name in all OSSGate SERVORD+ commands. Use of FQDN will result in a command failure (eg. "Gateway not found").
- This feature allows Small Lines, TGCP trunks and third party Large Lines gateway to use a free-format, up to 64 characters gateway FQDN.
- Only cable solution gateways support usage of default gateway domain name. Please note provisioning 64 character FQDN using free-format is recommended for “packet cable” gateways.

Table 1 Gateway profiles which support default gateway domain name

Gateway Profile Name	Gateway Profile Name	Gateway Profile Name
MOTOROLAMTA_1	ARRIS_TOUCHTONE_NN01_4	TOUCHTONE_NN01_2
MOTOROLAMTA_2	ARRIS_TOUCHTONE_NN02_4	TOUCHTONE_NN01_3
MOTOROLAMTA_4	TOUCHTONE_NN01_1	TOUCHTONE_NN01_4

38.3 CS2K-MT GUI functionality modifications

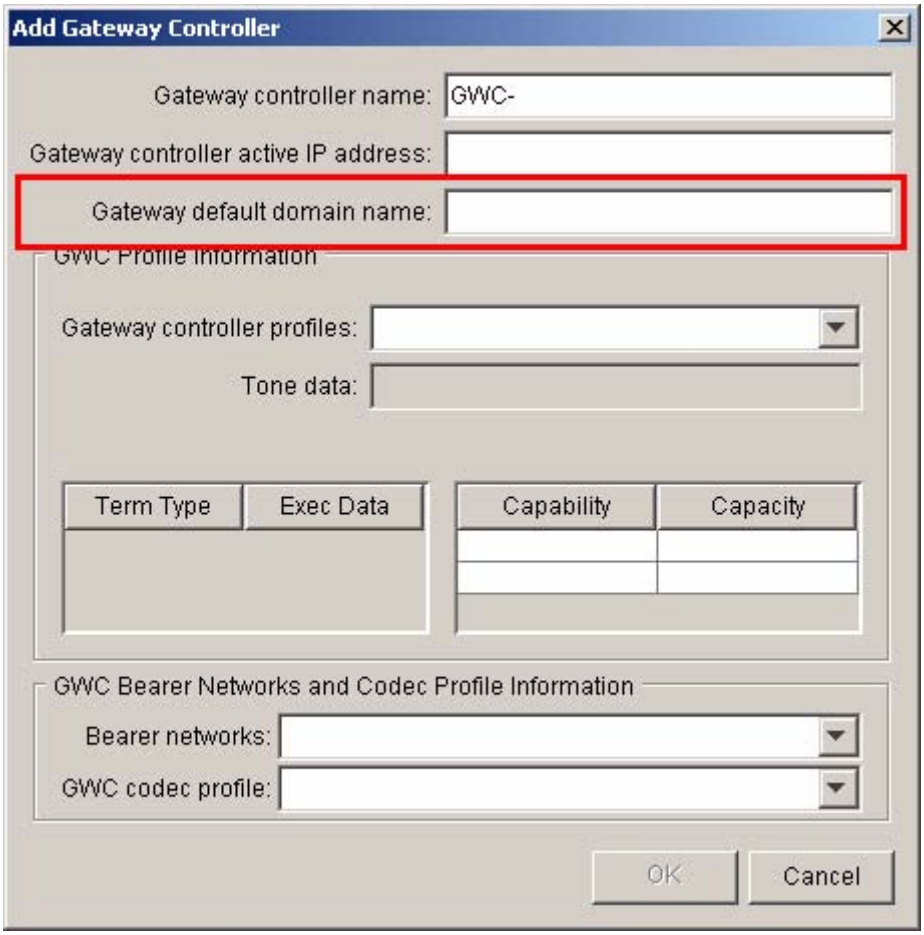
38.3.1 Add GWC node dialog

When adding GWC node, customer could set default gateway domain name. This name only can be used for cable solution gateways (refer to Table 1 on page 345).

If default gateway domain name is provisioned, only cable solution gateways can be associated on this GWC node. Any other gateway association will be rejected. Then the default gateway domain name will be applied to all associated cable solution gateways.

This field can be left empty if user don’t want to set default gateway domain name. In this case, not only cable solution gateways, but also other solution gateways can be associated.

Figure 1 Add GWC node dialog



Caution:

In SN09, only following GWC Profiles support cable solution gateways.

Table 2 SN09 GWC profiles which support cable solution gateways

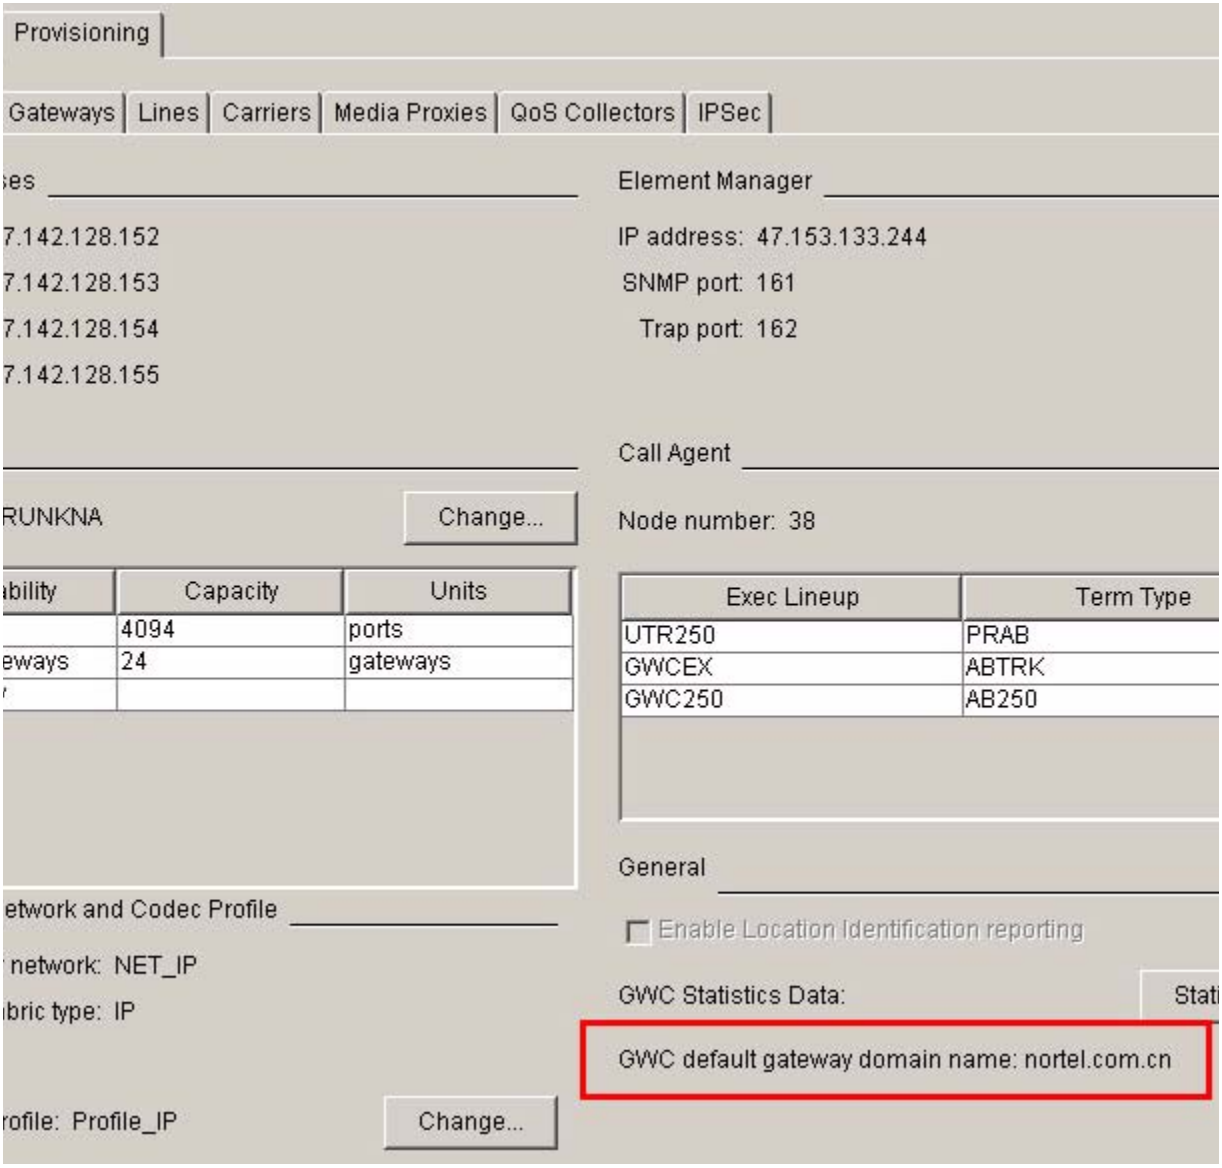
Gateway Contoller Profile Name
SMALL_LINESINTL
SMALL_LINESINTL_V2
SMALL_LINESNA
SMALL_LINESNA_V2

For other GWC Profiles, even if default gateway domain name can be provisioned, but any gateway association to this GWC will be rejected. Therefore, this field should be left empty if other GWC profiles are using, such as Packet Cable solution.

38.3.2 GWC provisioning display panel

If default gateway domain name was provisioned when adding GWC node, the domain name will be displayed on GWC provisioning display panel. If not provisioned, "<Not Configured>" will be displayed.

Figure 2 GWC provisioning display panel



38.3.3 Associate Media Gateway dialog

GUI layout of Associate Media Gateway dialog is not changed. But the usage of “Gateway Name” field is different than before.

38.3.3.1 Has default gateway domain name provisioned

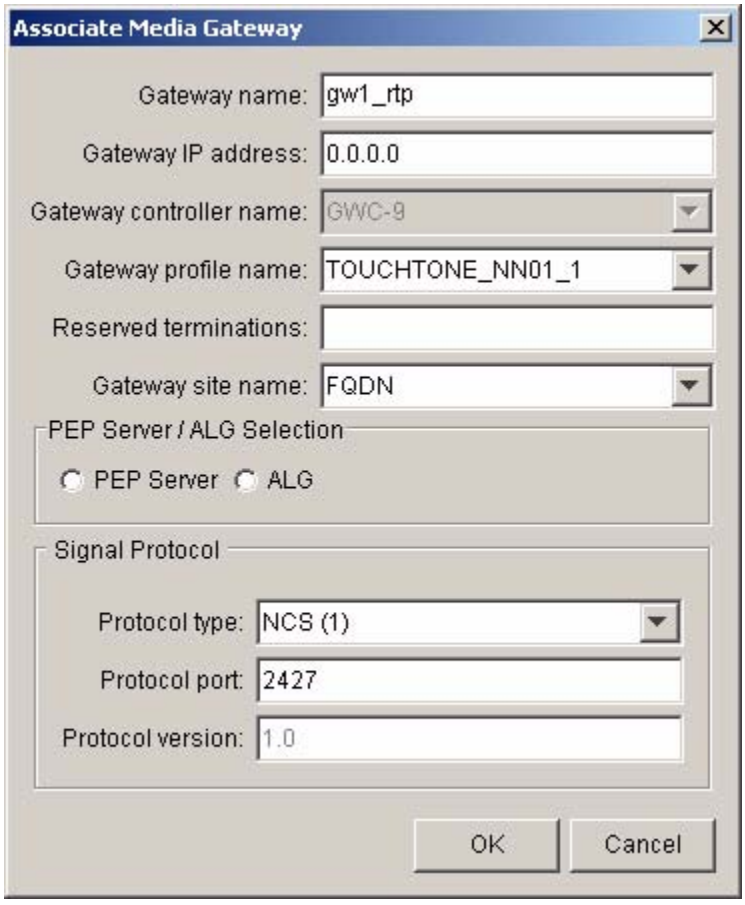
Since SN09, if a default gateway domain name is provisioned on the GWC, only cable solution gateways can be associated on this GWC (refer to Table 1 on page 345). Then the Gateway Name represents the gateway hostname. The FQDN is the concatenation of the Gateway Name and the default domain name, which together can contain up to 64 characters.

For example:

If the default domain name is “**nortel.com**”, And the user needs to provision a gateway with FQDN “**gw1_rtp.nortel.com**”, then input the Gateway Name field as the hostname “**gw1_rtp**”.

In this case, if the gateway is a PacketCable gateway, the Gateway Name "**gw1_rtp**" is downloaded to table LNENDPT on the Core, and it is also used for QoS record.

Figure 3 Associate Media Gateway Dialog



38.3.3.2 No default gateway domain name provisioned

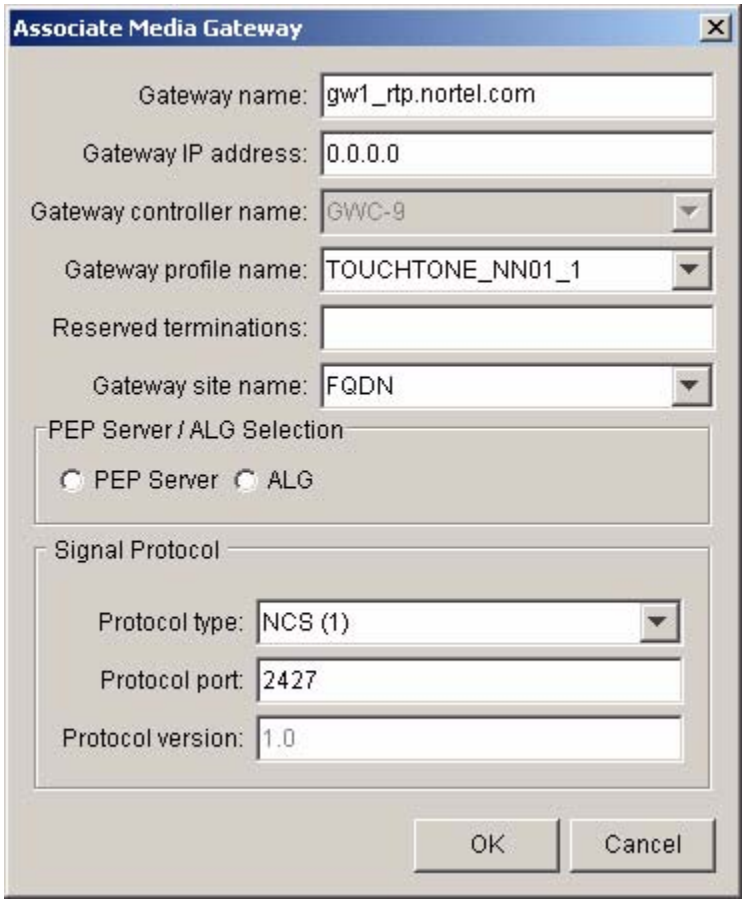
Since SN09, if default gateway domain name is not provisioned, then the Gateway Name represents the gateway FQDN, which can be free-format, up to 64 characters.

For example:

If the default domain name is not set and the user needs to provision a gateway with FQDN "**gw1_rtp.nortel.com**", then input the Gateway Name field as the FQDN "**gw1_rtp.nortel.com**".

In this case, if the gateway is a PacketCable gateway, the Gateway Name "**gw1_rtp.nortel.com**" is downloaded to table LNENDPT on the Core, and it is also used for QoS record.

Figure 4 Associate Media Gateway Dialog



38.3.4 Gateways display panel

On gateways display panel, gateway domain name or part of gateway FQDN can be used as retrieval criteria when querying gateway information. And gateway domain name will be displayed in separate column if provisioned.

38.3.4.1 Use default domain name

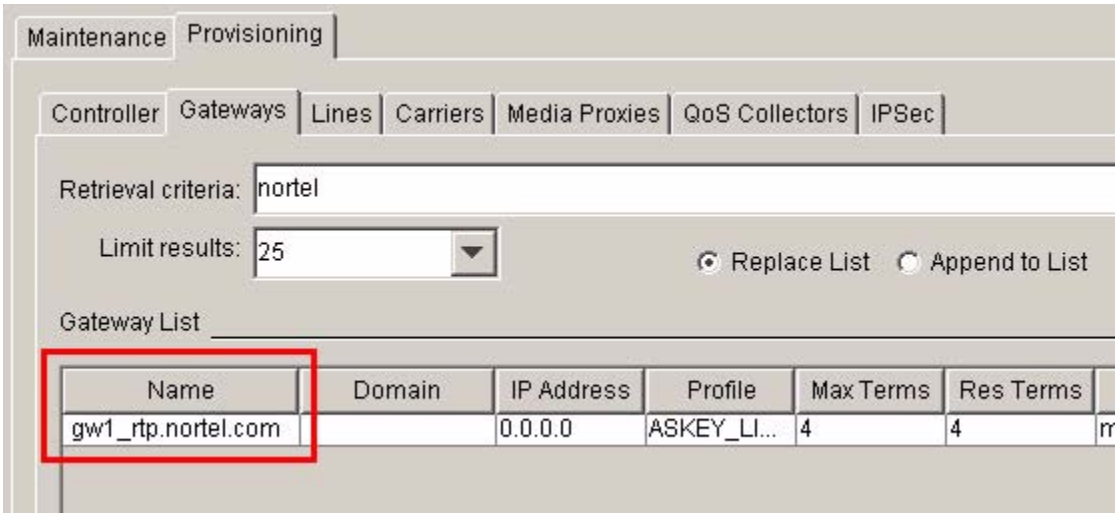
For those gateways using default gateway domain name, the gateway information will be displayed as following figure.

Figure 5 Gateways display panel - Case 1

38.3.4.2 No default domain name

For those gateways do not use default gateway domain name, the gateway information will be displayed as following figure.

Figure 6 Gateway display panel - Case 2



38.3.5 Lines display panel

On lines display panel, gateway domain name or part of gateway FQDN can be used as retrieval criteria when querying line information. And gateway domain name will be displayed in separate column if provisioned.

Figure 7 Lines display panel

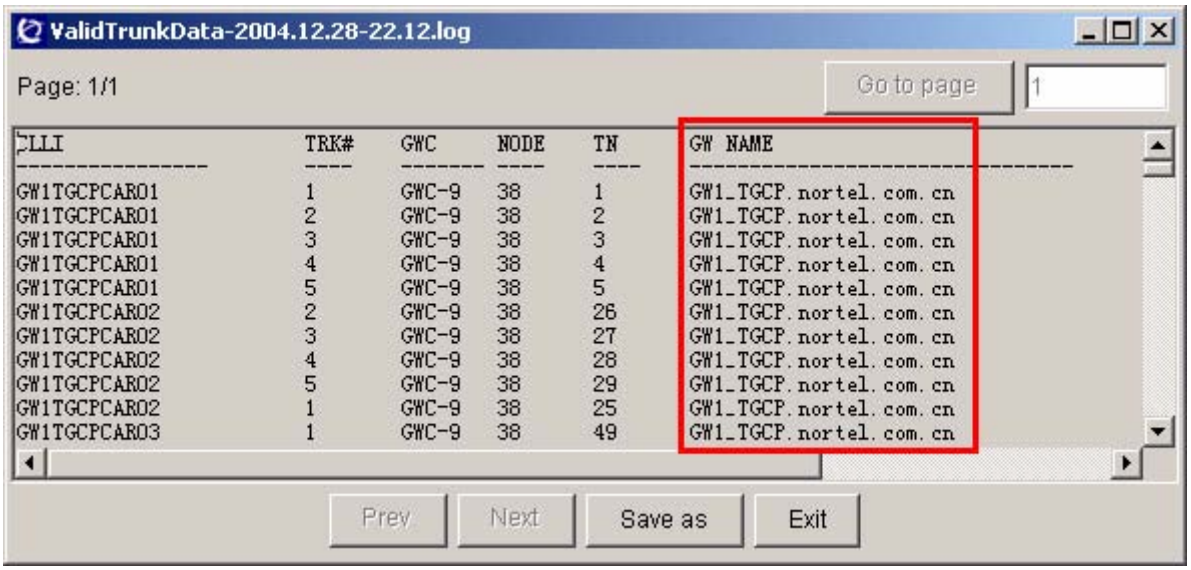
38.3.6 CS2K Audit

In all CS2K audit components (CS2K Data Integrity Audit, Line Audit and Trunk Audit), gateway FQDN can be recognized when running audit process.

If gateway domain name was provisioned, gateway FQDN will be displayed in audit report and possible correct action.

Figure 8 Line Data Integrity Audit report window

Figure 9 Trunk Data Integrity Audit report window



38.4 OSSGate functionality modifications

38.4.1 Nodes Provisioning interface

There are some changes on OSSGate Nodes Provisioning interface:

38.4.1.1 Add GWC node

A new parameter, gwDefaultDomainName, is added in the AddGWC xml command which is allowed user to input the gateway domain name if needed.

```
<?xml version="1.0" encoding="UTF-8" ?>

```

38.4.1.2 Query GWC

The Query GWC OSSGate xml command doesn’t need to be changed, but the response will be changed to include the gateway domain name, if the queried GWC has no domain name, this field will be null.

The QueryGWC response will be like following:

```
<?xml version="1.0" encoding="UTF-8" ?>
<CommandList>
```

```
<Response>
<Interface>cs2kCfgMgrIf</Interface>
  <Methods>
    <queryGWC usn="1" version="1.0">
    <ReturnData>

```

38.4.1.3 Query Media Gateway

Although the gateway might be associated with a default domain name, but in the OSSGate QueryMG response, only the gateway host name will be returned.

So no changes was made on QueryMG operation.

38.4.2 Other OSSGate interfaces

For all of other OSSGate interfaces, format of request/response messages are not modified. The only changes are:

- If gateway name is required in the request message, both of gateway name and gateway FQDN can be used.
- If gateway name is filled in request message, the same gateway name will be returned in the response message, no matter if default gateway domain name is provisioned.
- If gateway FQDN is filled in request message, the same gateway FQDN will be returned in the response message (excepts Query Media Gateway interface).

This applies to following OSSGate interfaces:

38.4.2.1 Nodes Provisioning

- disAssocGWC
- disAssocMG
- changeMG
- deleteGWCfromCS

38.4.2.2 Trunk Provisioning

- AddTuple
- DelTuple
- ReplaceTuple
- GetRange
- GetTuple

38.4.2.3 Carrier Provisioning

- AddCarrier
- DeleteCarrier
- GetCarrier
- GetEndpoint
- ListAllCarriers

38.4.2.4 Trunk Maintenance

- PostByGatewayName

- QESByGatewayName
- BSYByGatewayName
- RTSByGatewayName
- INBByGatewayName
- FRLSByGatewayName
- PostByCarrier
- QESByCarrier
- BSYByCarrier
- RTSByCarrier
- INBByCarrier
- FRLSByCarrier
- PostByTrunkClli
- BSYByTrunkClli
- RTSByTrunkClli
- INBByTrunkClli
- FRLSByTrunkClli
- PostGroupDChannelByTrunkClli
- GetTrunkCllisByGatewayName
- GetGatewayNames
- GetCarriers

38.4.2.5 Line Provisioning

All SERVORD+ commands which support GW/endpoint names will NOT support the use of a gateway name which contains the default domain name assigned to the gateway's hosting GWC. If the gateway is provisioned on a GWC which has a default gateway domain name assigned, only the gateway hostname (specified at gateway creation time) may be used in the SERVORD+ command. Examples of commands for such a gateway are as follows:

Gateway "testgwname" is provisioned on a GWC which has a default gateway domain name of "us.nortel.com" assigned.

Supported Hostname only:

EST $ DLH 5200999 1FR Lata1 0 ***testgwname*** aaln/1 ***testgwname.1*** aaln/1 $ DGT $ 3

QTP ***testgwname*** aaln/1

Unsupported FQDN:
EST $ DLH 5200999 1FR Lata1 0 ***testgwname.us.nortel.com*** aaln/1 ***testgwname.1.us.nortel.com*** aaln/1 $ DGT $ 3

QTP ***testgwname.us.nortel.com*** aaln/1

Query output will always provide FQDN information if available in the GWCEM if the gateway is initially provisioned with a FQDN (ie. does not use the a GWC's default gateway domain name). If the gateway is provisioned on a GWC which has a default gateway domain name assigned, then only the hostname entered at gateway provisioning time will be returned in the query output.

38.4.2.5.1 Limitations

Gateways which are provisioned with domain information imbedded within the user provided hostname and assigned to GWCs without a default gateway domain name, will always return the user-assigned, domain-imbedded name in queries and will always require the user-assigned, domain-imbedded name in non-query commands (eg. NEW, OUT, etc..).

Example 1:
A user associates gateway ***"testgwname.us.nortel.com"*** to GWC-0. GWC-0 is *not configured* with a default gateway domain name. When the gateway is provisioned in this manner, all SERVORD+ queries (QLEN/QDN/QTP/etc) will return ***"testgwname.us.nortel.com"*** in ouput and all SERVORD+ non-query commands (NEW/EST/OUT/etc) will require ***"testgwname.us.nortel.com"*** in the relevant command string.

Query command and output format:

```
> QTP testgwname.us.nortel.com aaln/4
------------------------------------------------------------------
---
LEN:     UAIP  00 0 00 03
END POINT: testgwname.us.nortel.com  aaln/4
TYPE: SINGLE PARTY LINE

NON-Query Formats allowed:

EST $ DLH 5200999 1FR Lata1 0 ***testgwname.us.nortel.com*** aaln/1 ***testgwname.us.nortel.com*** aaln/2 $ DGT $ 3

Gateways which are provisioned without domain information imbedded within the user provided hostname and assigned to GWCs which specify a default gateway domain name, will always return the user-assigned host name in queries and will always require the user-assigned host name in non-query commands (eg. NEW, OUT, etc..).

Example 2:
A user associates gateway ***"testgwname.1"*** to GWC-0. GWC-0 is *configured* with a default gateway domain name ***"ibm.com"***. When the gateway is provisioned in this manner, all SERVORD+ queries (QLEN/QDN/QTP/etc) will return ***"testgwname"*** in output. Non-query SERVORD+ commands (NEW/EST/OUT/etc) will allow only ***"testgwname.1"*** in the relevant command string.

Query command and output format:

> QTP ***testgwname.1*** aaln/4
yields

```
------------------------------------------------------------------------

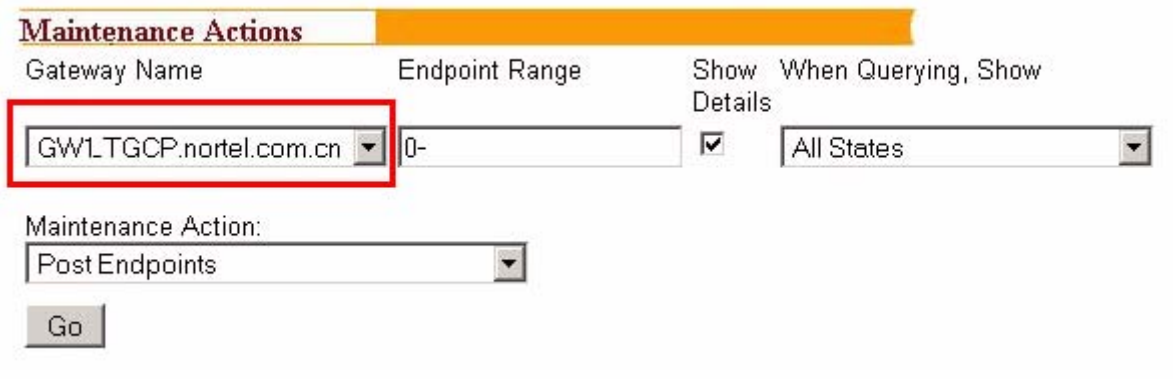
38.5 TMM functionality modifications

38.5.1 Maintenance By Gateway Name

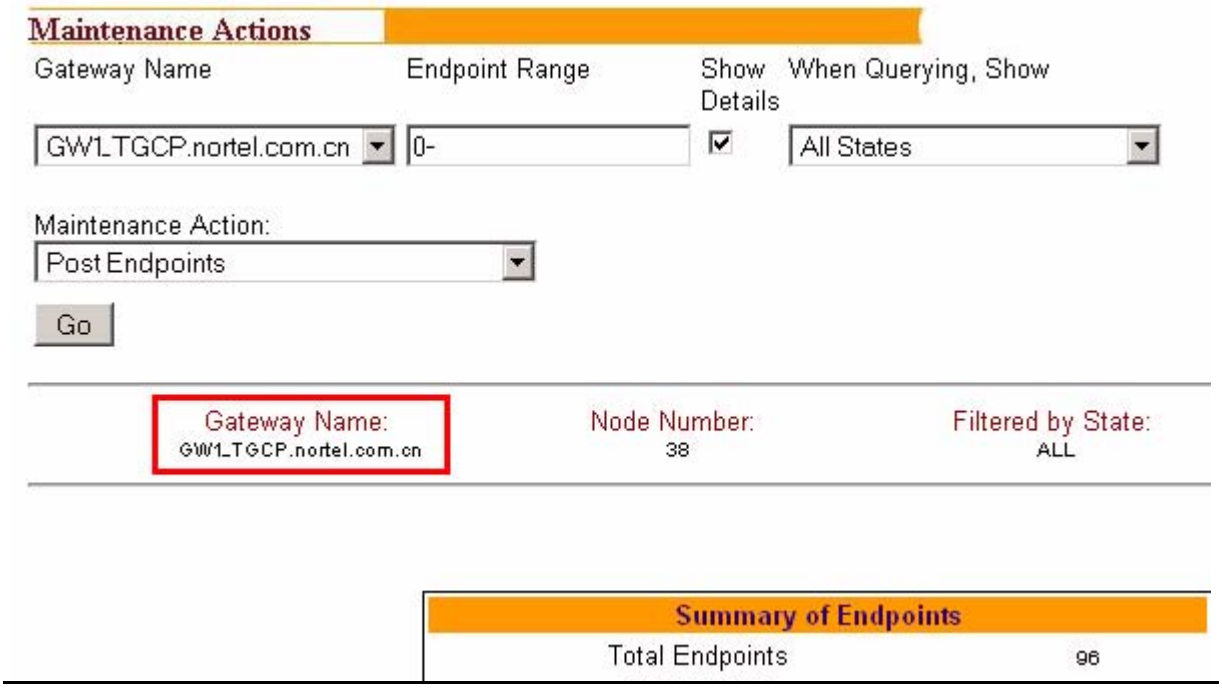
In SN09, gateway FQDN up to 64 characters will be automatically retrieved and displayed on TMM GUI.

Figure 10 FQDN gateway name retrieval - MtcByGatewayName



If user performs maintenance actions such as Post and Busy, Gateway FQDN will be displayed on state output.

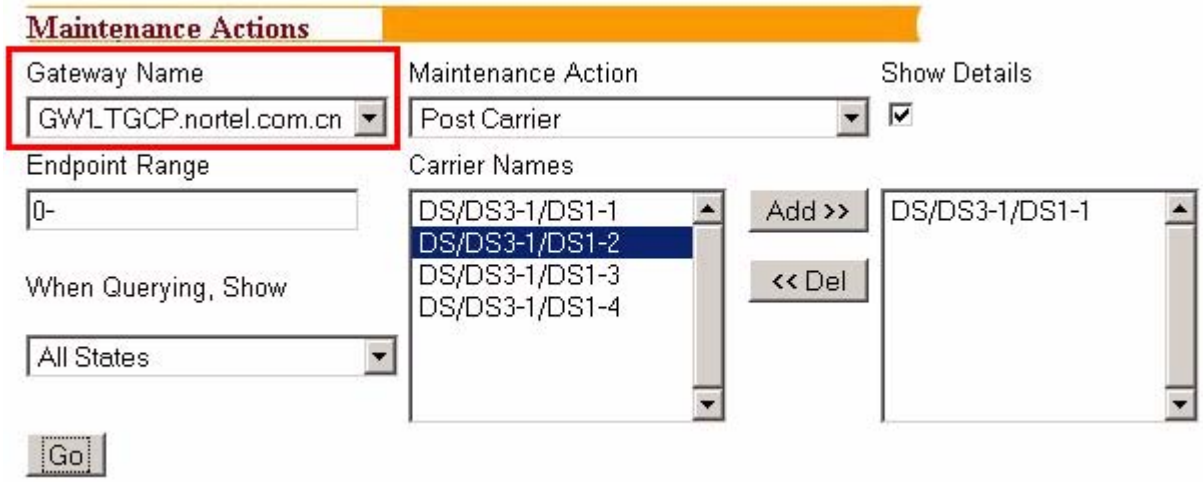
Figure 11 Mtc by Gateway Name state output



38.5.2 Maintenance By Carrier

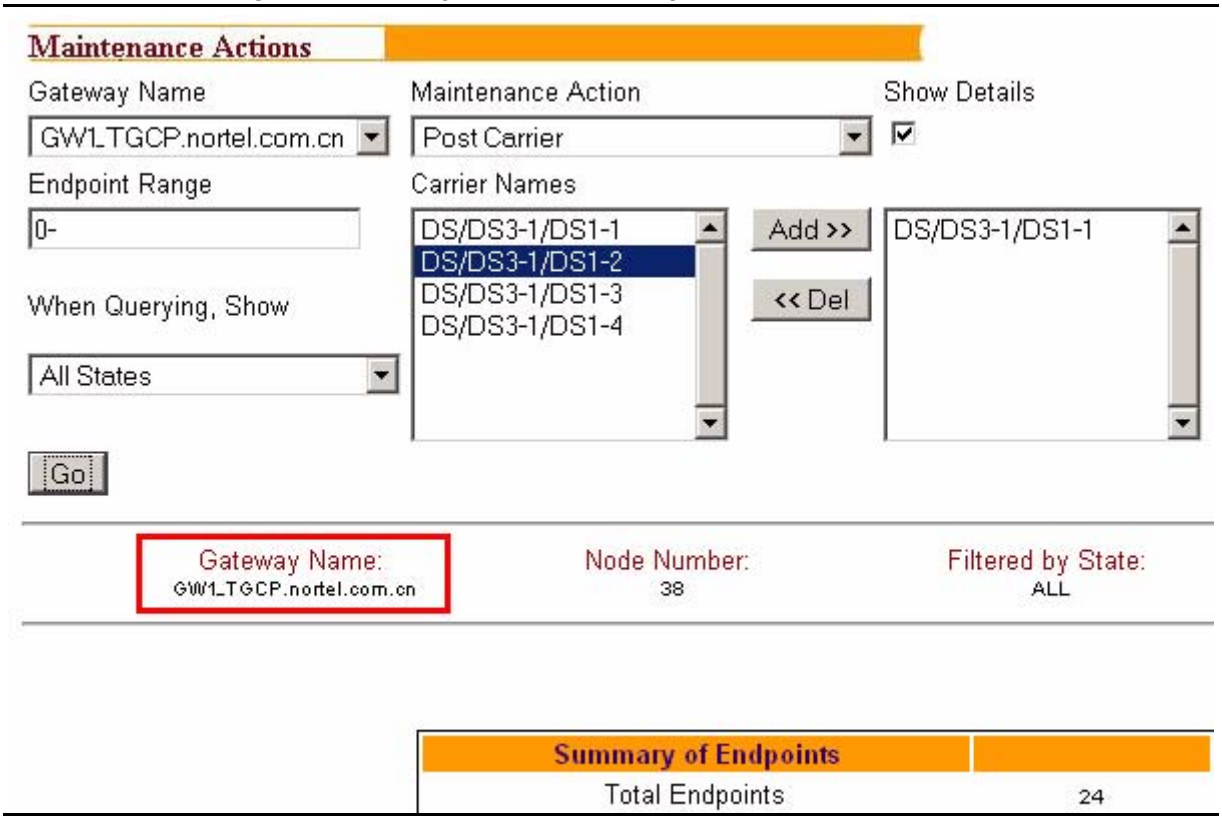
In SN09, gateway FQDN up to 64 characters will be automatically retrieved and displayed on TMM GUI.

Figure 12 FQDN gateway name retrieval - MtcByCarrier



If user performs maintenance actions such as Post and Busy, Gateway FQDN will be displayed on state output.

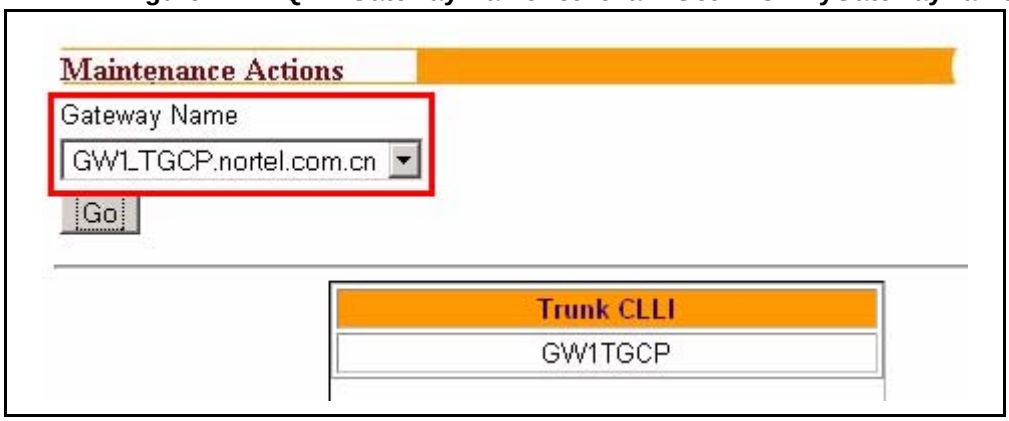
Figure 13 Mtc by Carrier state output



38.5.3 Get TrkCLLIs by Gateway Name

In SN09, gateway FQDN up to 64 characters will be automatically retrieved and displayed on TMM GUI.

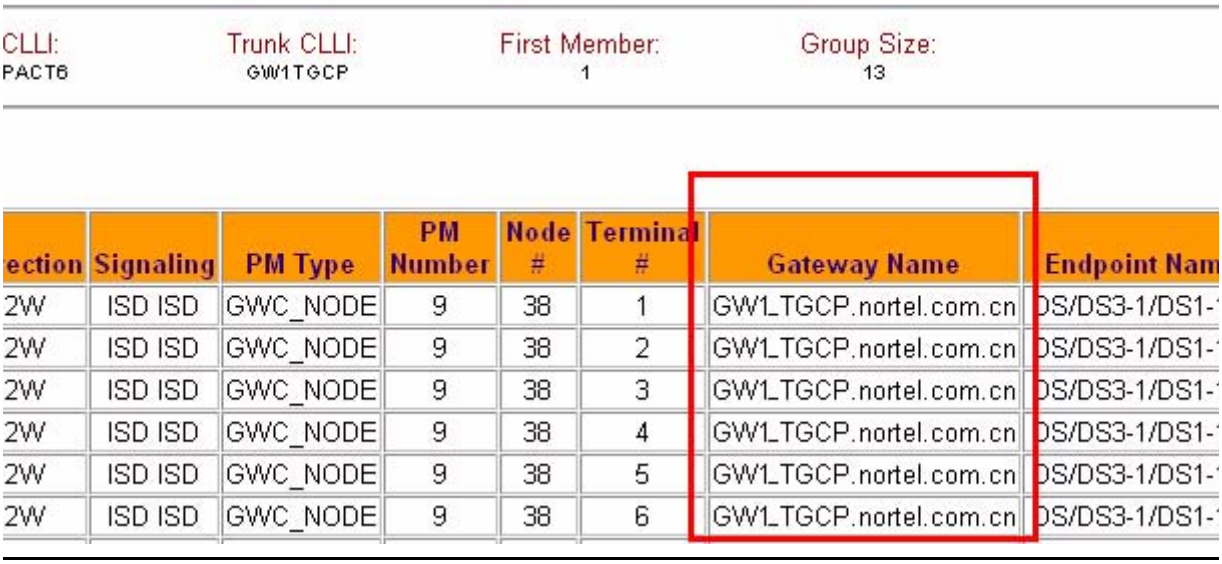
Figure 14 FQDN Gateway Name retrieval - GetTrkCliiByGatewayName



38.5.4 Maintenance By Trunk CLLI

If user performs maintenance actions such as Post and Busy, Gateway FQDN will be displayed on detailed trunk member information.

Figure 15 Mtc by Trunk CLLI



CLLI: PACT6 | Trunk CLLI: GW1TGCP | First Member: 1 | Group Size: 13

38.6 LMM functionality modifications

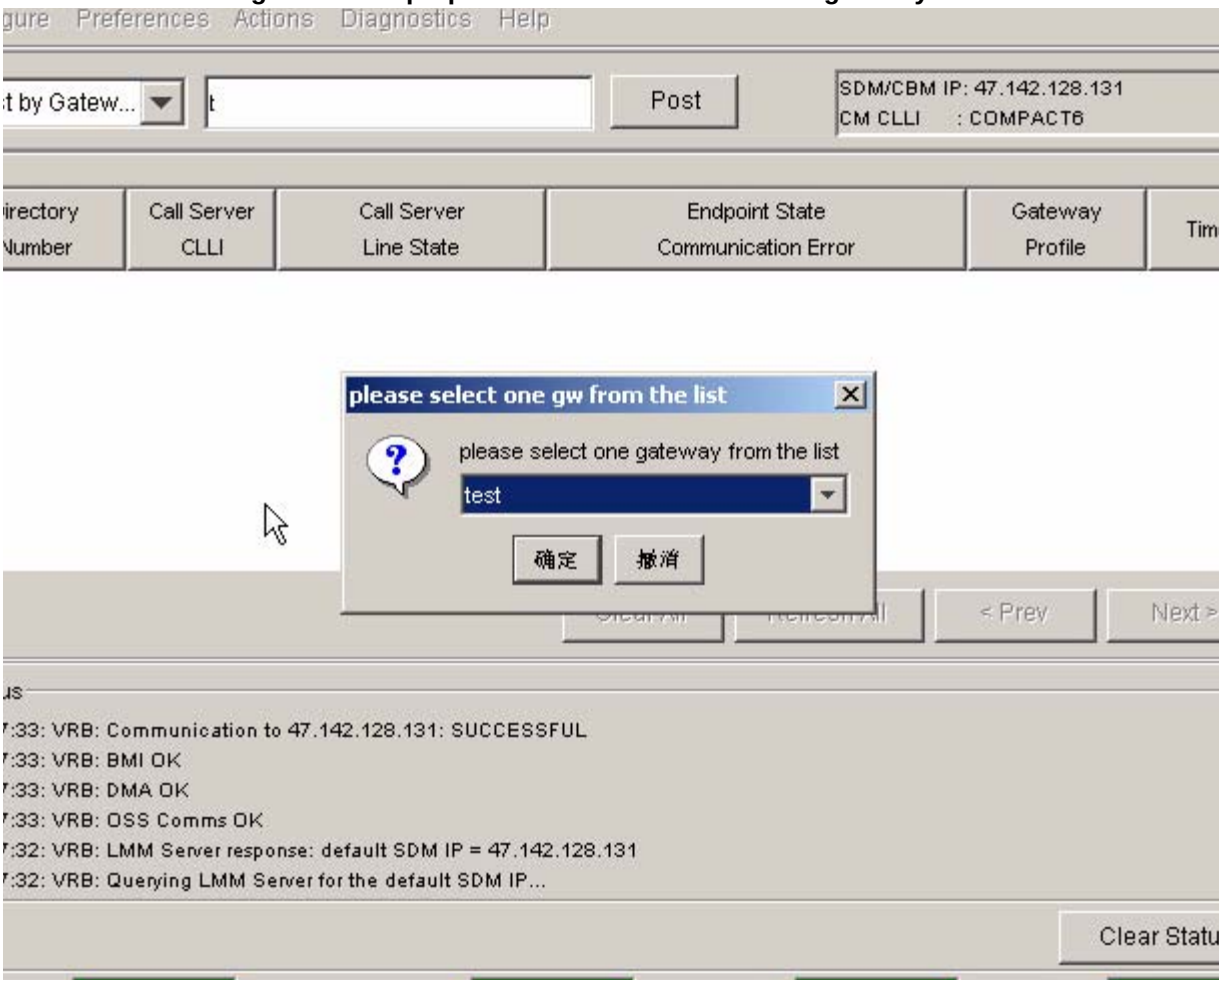
38.6.1 “Post by Gateways” operation

“Post By Gateways” can provide users the functionality to post all the DNs that is associated with the specific gateway, in SN08, all the gatways are hostname,

but in SN09, both gateway hostname and full FQDN name are all needed to be supported to post the DN.

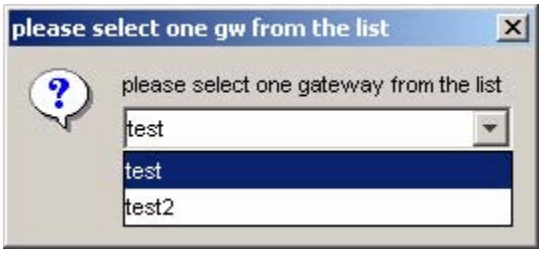
In SN09, the “Post by Gateway” can support the partial query, which means user can input only one part of the gateway name (either gateway hostname or full FQDN name), if there have more than one gateways which can match the partial string, a select box will be pop-uped to let user to choose one, if there is only one gateway to match the query string, it will be used to retrieve all the DNs and no box will be pop-uped.

Figure 17 Pop-up select box if more than one gateways are returned



User can select one gateway from the select box such like the following.

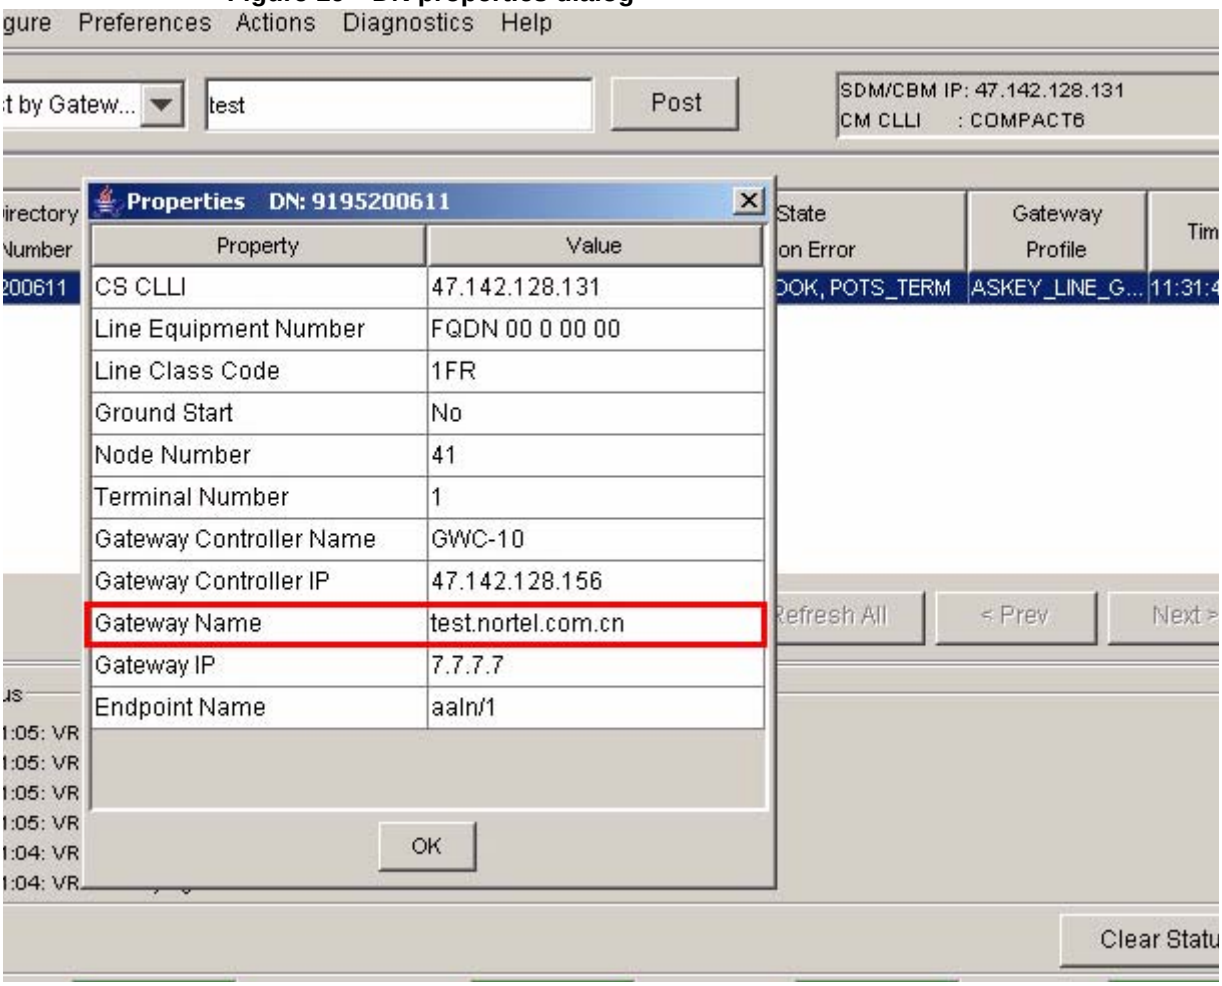
Figure 18 gateway select box



38.6.2 DN's properties dialog

When user right click on a DN and choose the "properties" menu, a DN's properties dialog will appear to show all the properties for the selected DN which includes a gateway name field. If the gateway is associated with a default domain name, the full FQDN name will be displayed in the gateway name field like following diagram.

Figure 19 DN properties dialog



38.7 Other Tools

38.7.1 QGW command on Core

Table LNENDPT is sorted by LENs and may contain up to 150,000 tuples. Therefore, finding all the LENs & Endpoints for a particular Gateway can be somewhat difficult.The Query Gateway Tool (QGW) is a tool on the CM that can be used to output all the LENs and Endpoints for the specified Gateway in table LNENDPT.

To use the command, enter the QGW command at the CM CI prompt, followed by a string denoting the Gateway name. Below is an example of the use of the command:

```
CI:
>qgw 'sbv-10.com6.net'
-------------------------------------------------------
--
LEN: LG    00 0 00 00     ENDPOINT: aaln/1
LEN: LG    00 0 00 01     ENDPOINT: aaln/2
-------------------------------------------------------
--
```

If the Gateway does not exist in table LNENDPT, the following error message is output:

```
>qgw 'sbbv-11.com6.net'
ERROR   - Gateway Name does not exist in table LNENDPT
```

38.8 Hardware Requirements or Dependencies

None.

38.9 Software Requirements or Dependencies

None.

38.10 Limitations and restrictions

1. When associating media gateway, gateway hostname and FQDN must be unique across whole office, otherwise it will be rejected.
2. If a default gateway domain name is provisioned, then together the Gateway Name and the default gateway domain name cannot exceed 64 characters. This rule only be applied to cable solution gateways. Refer to Table 1 on page 345.
3. If no default gateway domain name provisioned, Small line gateways, TGCP trunking gateway and third party gateway's max name length can up to 64 characters.

38.11 Interactions

None.

39: Functional Description (FN): A00009190

39.1 Feature name and Feature ID

A00009190: Universal Carrier Protocol (UCP) C7UPTMR Enhancements

39.2 Description

This activity in SN09 provides provisionable timer support on a per trunk basis for UCP Trunks. This is accomplished by

- Provisioning timers in table C7UPTMR for UCP protocol.
- Provisioning the C7UPTMR index in table TRKSGRP
- This feature will be tracked by Track SOC UCSB0001.

When there is no C7UPTMR index provisioned in table TRKSGRP, the default timer values are used.

Currently, the XPM patch XIX20, is used to hardcode the ACM timer value to 20 secs for UCS trunks. When the switch is upgraded to SN09 core load, this patch XIX20 will be Obsoleted. New patch, XHW10 for DTC should be applied to support provisionable timers on a per trunk basis for UCP Trunks. When trunks hosted on DTCs are used, this patch will allow the datafilled ISUP timer value to be used during CallP.

- Datafill table C7UPTMR for UCP Potocol with the required timer value.
- Datafill TRKSGRP to change the TMRNAME field to the datafilled C7UPTMR index.

39.2.1 Provisioning Table C7UPTMR

Table C7UPTMR provides the ability to provision various ISUP timer values on a per-protocol and direction basis. The ISUP (ISDN User Part) timer values that can be provisioned in table C7UPTMR are dependent on the protocol. This activity supports provisioning of timers for UCP protocol. The new UCP timer implementation is modeled after the existing provisionable timers for the Q764 protocol. Refer to the following figure for a sample UCP C7UPTMR datafill.

Figure 1 Examples of the C7UPTMR Datafill

```
TABLE C7UPTMR
UCP2W 2W UCP 13 2 30 6 60 10 180 20 200 13 60 2 $
UCPIC IC UCP 13 6 60 20 200 13 60 $
UCPOG OG UCP 2 25 6 60 10 180 13 60 2 $
```

Refer to the following table for a brief description of the UCP timers, range and default values.

Table 1: UCP Timer Description

Timer Name ANSI	Timer Name Bellcore	Table C7UPTMR Field Name	Timer Range (Secs)	Default Value (Secs)	Direction Applicable	Description
COT	$T_{ccr,r}$	COT	10 to 15	13	IC, 2W	When responding to a continuity check request (CCR), awaiting a Continuity Test message (COT) or Release (REL)
T21	T_{cot}	TONE	2 to 2	2	OG, 2W	When responding to a continuity check in an Initial Address Message (IAM), awaiting return of suitable tone
ACM	T_{iam}	ACM	20 to 30	25	OG, 2W	When sending Initial Address Message IAM, awaiting Address Complete Message (ACM), Answer (ANM) or Release (REL).
REL	T_{rel}	RLCSREL	4 to 15	6	IC, OG, 2W	When sending REL, awaiting Release Complete (RLC); shorter timer used for retransmission
RLC	$T_{rel,l}$	RLCLREL	60 to 60	60	IC, OG, 2W	When sending REL, awaiting RLC; longer timer used for abnormal procedures
T7	unnamed	IRETEST	1 to 10	10	OG, 2W	Wait before initial COT retest
T8	unnamed	SRETEST	60 to 180	180	OG, 2W	Wait before subsequent COT retest
T11	$T_{cot,r}$	ICCR	16 to 20	20	IC, 2W	When receiving first COT coded “failed”, awaiting receipt of CCR
T13	$T_{cot,l}$	SCCR	180 to 300	200	IC, 2W	When receiving subsequent COT coded “failed”, awaiting receipt of CCR
T15	T_{rsc}	RLCSRSC	4 to 15	13	IC, OG, 2W	When sending Reset Circuit message (RSC), awaiting RLC; shorter timer used for retransmission
T16	$T_{rsc,l}$	RLCLRSC	60 to 60	60	IC, OG, 2W	When sending RSC, awaiting RLC; longer timer used for abnormal procedures

Table 1: UCP Timer Description

Timer Name ANSI	Timer Name Bellcore	Table C7UPTMR Field Name	Timer Range (Secs)	Default Value (Secs)	Direction Applicable	Description
T20	T_{ccr}	LPA	2 to 2	2	OG, 2W	When sending a CCR, awaiting receipt of Loop Back Acknowledgement

This feature will be tracked by Track SOC UCSB0001.

39.2.2 Provisioning Table TRKSGRP

Table TRKSGRP provides the ability to provision C7UPTMR index per trunk subgroup basis in field TMRNAME. The provisioned timers values are used for UCP call processing.

Figure 2 Example of the TRKSGRP Datafill

```
TABLE TRKSGRP
LOOP3IMT2WS7A 0 DS1SIG C7UP 2W N N EXTERNAL NONE UCP THRH 0 DMSNODE
$ UCP2W CIC
```

Once TMRNAME field is updated in the Table TRKSGRP, BSY; RTS the trunk to make sure that the C7UPTMR INDEX for the trunk is reflected at the peripherals (GWC/XPM/SPM).

40: Functional Description (FN): A00009200

40.1 Feature name

Packet Trunking Trunk Test: Milli-watt Tone Swap

40.2 Description

The purpose of this feature is to provide the customer the capability to perform a function known as Milli-watt Tone Swap from the MAPCI TTP interface on a Gateway TDM trunk circuit in the Succession XA-Core non-hybrid and Compact CS2K platforms. The new command is supported for all fabrics where the AudioCodes Media Server 2000 series media servers are supported, which includes AAL2, AAL5, and IP. The AAL1 solution is not being considered at this time (as no AudioCodes Media Server is supported in that solution) and no verification is being planned. This feature utilizes the combined capabilities of the XA-Core, Audio Controller (AC) and AudioCodes Media Server (AMS).

Milli-watt Tone Swap is defined as passing a well known tone, the milli-watt tone of 1004 Hz., at a selectable power level, over a DS-0 trunk circuit on a Gateway TDM trunk, to a far-end switch wherein the amount of transmission loss can be measured. Simultaneously and independently, the far-end switch will pass the same 1004 Hz. tone back over the same trunk circuit wherein the amount of transmission loss can then be measured by the near-end switch. This operation permits the customer to ensure two-way voice path is present and verify trunk padding is set correctly.

This feature introduces a new command, MWTSwap, from the MAPCI TTP interface, available only on the Succession CS2K & Compact CS2K platforms. The hardware required to perform the test will reside in the AudioCodes Media Server 2000 Series products.

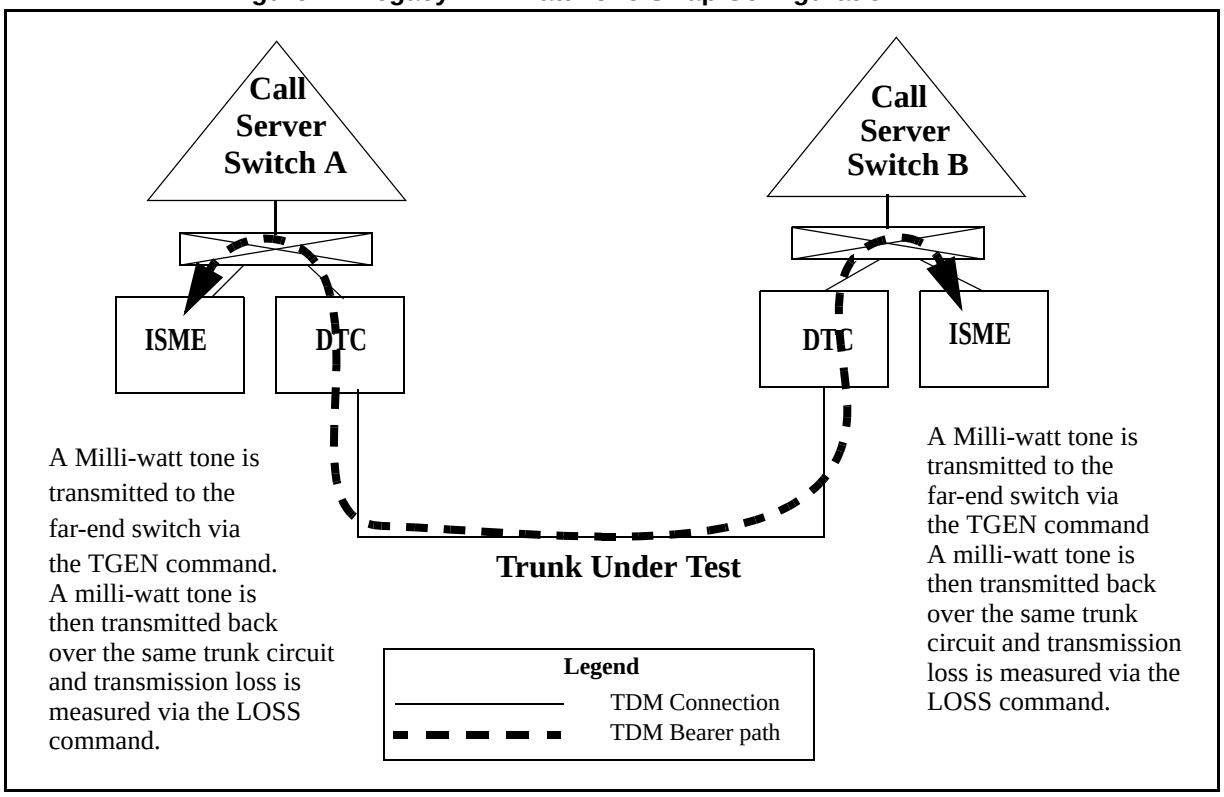
40.3 Configuration Overview

40.3.1 Legacy DMS Milli-watt Tone Swap Configuration

In a conventional DMS configuration Milli-watt tone swapping can be performed via the combination of the TGEN and LOSS commands located on the MAPCI TTP interface. The user must perform each function of the Milli-watt tone swap separately, once to generate the desired milli-watt tone with the TGEN command, followed by a loss measurement with the LOSS command while the far-end is generating the tone. This command implementation does not permit the user to perform both functions simultaneously. Milli-watt tone swap in legacy is executed using special hardware in the Integrated Service Module Equipment or ISME connected to the ENET. Both command requests

are originated by the user from the MAP interface. Connections are created between the Trunk Under Test and the appropriate trunk testing hardware resident on a local ISME. In order to perform Milli-watt tone swap a coordinated effort must be made between craft persons at both switches.

Figure 1 Legacy Milli-watt Tone Swap Configuration



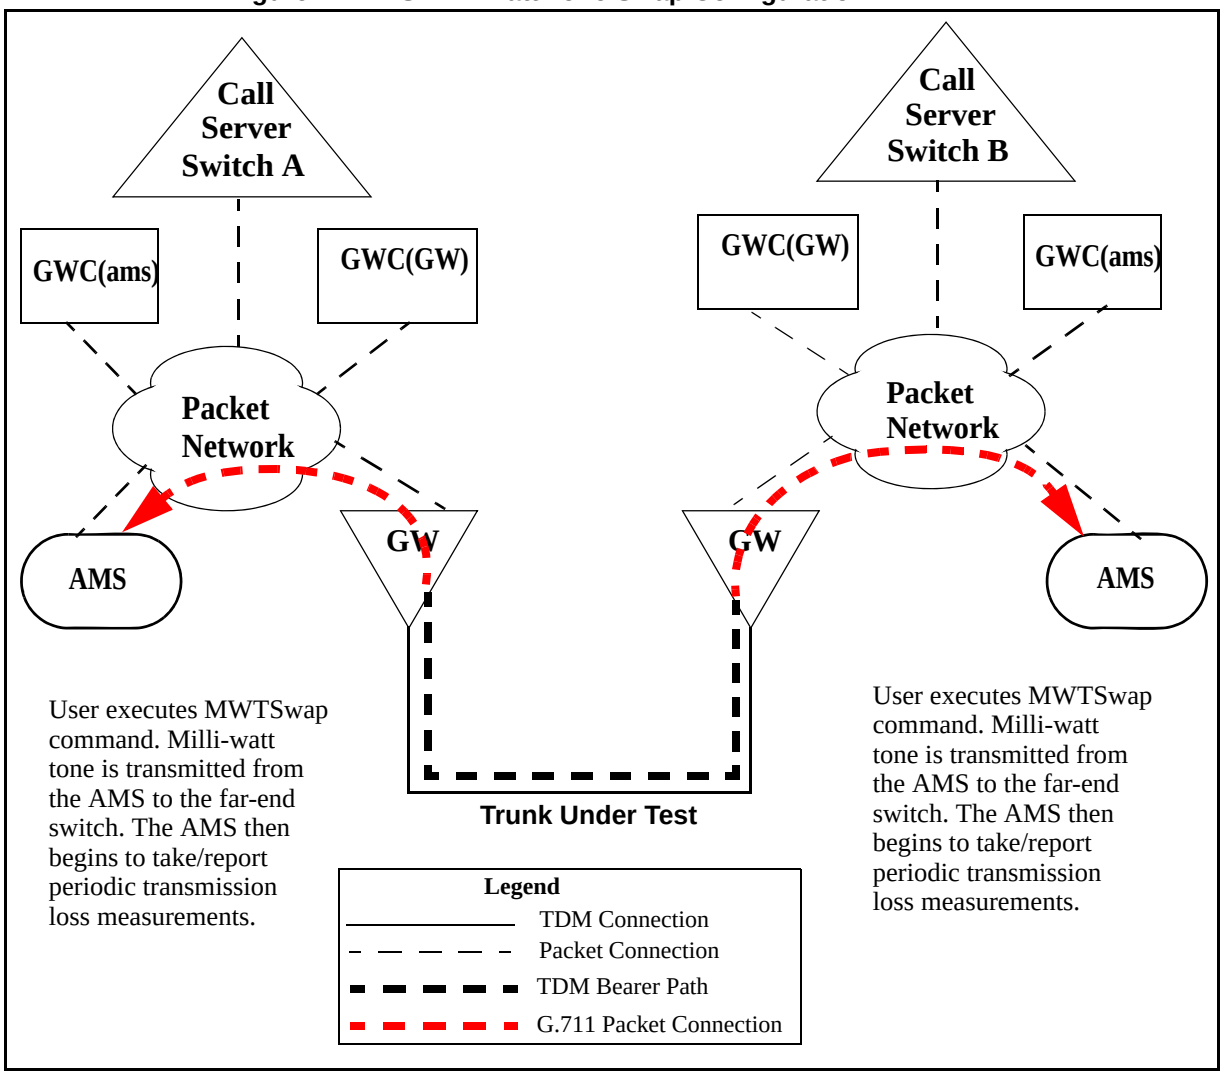
40.3.2 Packet Milli-watt Tone Swap Configuration

The implementation of this feature offers a new method of conducting milli-watt tone swapping via the DSP hardware resident in the AudioCodes Media Server (AMS) 2000 series products. This configuration has the capability of operating without the need for an ENET or ISME. A new command will be introduced at the MAPCI TTP interface called MWTSwap. This new command will perform both the tone generation and loss measurement functions simultaneously.

When the crafts-person invokes the new command, connections are established between the AMS and the Gateway TDM Trunk Under Test. A milli-watt tone is then generated towards the far-end switch. Simultaneously, transmission loss measurements will be taken, on a periodic basis, on the same trunk circuit and displayed on the MAP screen. In order to perform Milli-watt tone swap a coordinated effort must be made between craft persons at both

switches, but because the two functions are executed together the coordination required is less.

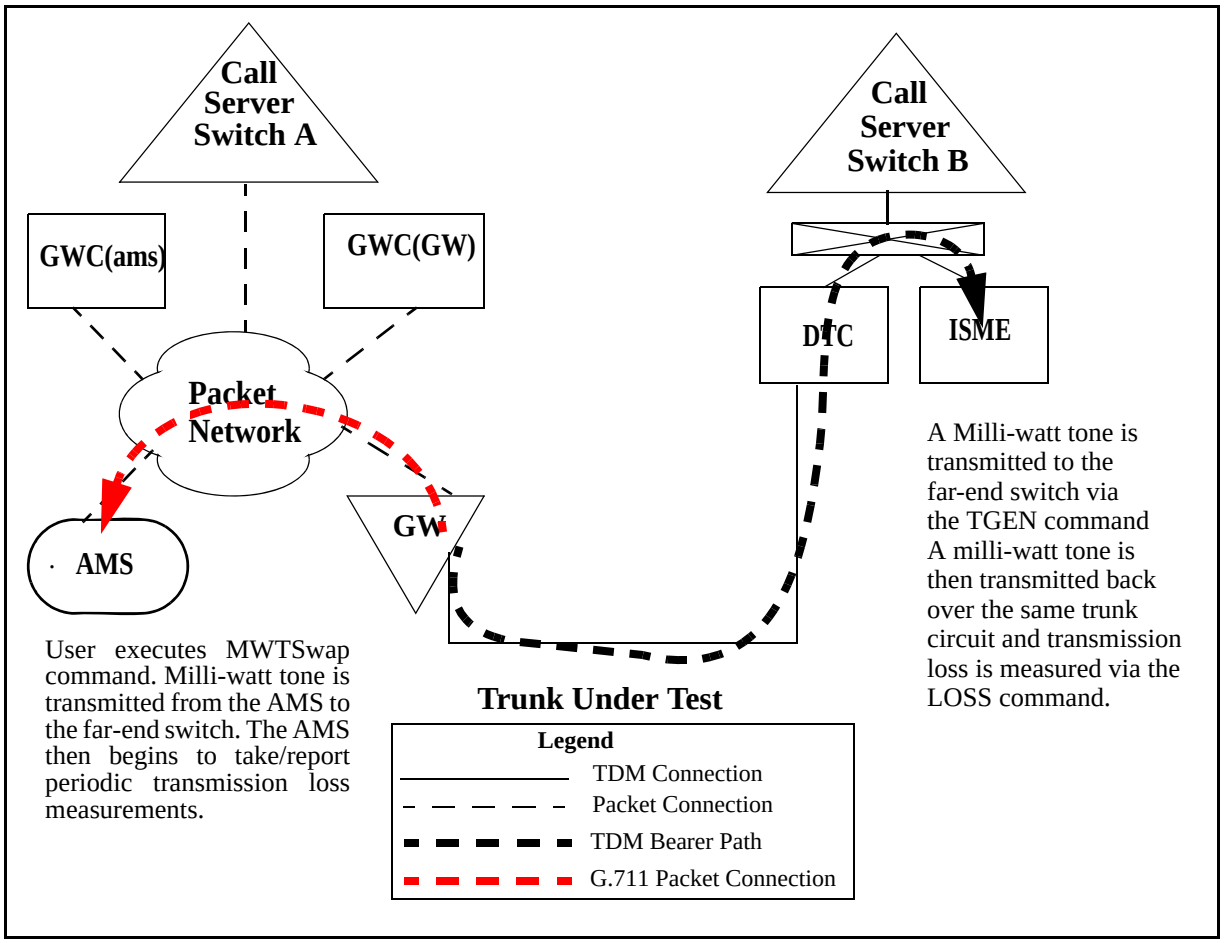
Figure 2 AMS Miili-watt Tone Swap Configuration



40.3.3 Packet Milli-watt To Legacy Tone Swap Configuration

The implementation of this feature also permits the user the ability to interoperate with legacy switches (either Nortel or other vendors). In this case if the user wishes to perform Tone Swap to an adjacent switch, which hosts non-AMS based test equipment, the user would simply issue the MWTSwap command and coordinate with the craftsperson at the adjacent switch to activate their hardware to perform tone swap. The above example shows Tone Swap between a packet-based switch and a DMS legacy switch..

When the crafts-person invokes the new command, connections are established between the AMS and the Gateway TDM Trunk Under Test. A milli-watt tone is then generated towards the far-end switch. Simultaneously, transmission loss measurements will be taken, on a periodic basis, on the same trunk circuit and displayed on the MAP screen. In order to perform Milli-watt tone swap a coordinated effort must be made between craft persons at both switches, but because the two functions are executed together the coordination required is less.



40.4 Functional Overview

As mentioned earlier this feature will introduce a new command at the MAPCI TTP level interface. The new command, MWTSwap, will appear on the TTP level screen only when the office parameter EXTERNAL_GATEWAY_TEST_LINES is set to ‘Y’ in table OFCVAR. This office parameter determines which test head will be used for hardware based TTP/ATT level trunk testing. The default is ‘N’ which indicates that tests will use the existing hardware located in the ISM/MTM peripheral. When set to

'Y', all testing currently supported will be performed via the AudioCodes Media Server (AMS) 2000 series products.

Please note: AMS based testing is only supported on Gateway TDM trunks. No support is currently available for legacy peripheral TDM trunks. Legacy peripheral TDM trunks can utilize the existing TTP Manual level command TGEN and Loss in combination to perform a Tone Swap.

The following is an example of the new command on the MAPCI TTP level interface.

```

```

When the ofcvar EXTERNAL_GATEWAY_TEST_LINES is activated the MWTSwap command will appear as a menu item to the crafts person. Note that the commands TGEN and Loss will be removed as menu items since they are currently not supported in the XA-Core non-hybrid and compact CS2K solution.

The following steps are performed to execute the command MWTSwap from the MAPCI TTP MANUAL level interface both on a Succession XA-Core non-hybrid or Compact CS2K platform.

1. Crafts person posts a trunk circuit which will be tested at the MAPCI TTP level interface.
2. The crafts person enters the MANUAL level.

3. The command MWTSwap is executed with the optional parameters to specify the tone frequency, power level, and test duration. If no optional parameters supplied, the default parameters are used, which are 1004 Hz. at 0 dB for 60 seconds.

   Please note although the command line interface provides for entering a tone frequency, only the 1004 Hz. frequency is supported for this feature. If a frequency other than 1004 Hz. is entered, the crafts person will be alerted with an error message.

4. Trunk is seized and connections established between the AMS and Gateway TDM trunk, the AMS is sent a request to perform the test.
5. Tone is generated on the outgoing Gateway TDM trunk, at the same time the AMS begins taking loss measurements and reporting them back to the CS2K.
6. The MAPCI TTP level interface is updated with the loss measurements on a periodic basis (every few seconds).
7. After the test duration completes the AMS will time out and release the connection and terminate the test.
8. The MAP screen will be cleared and the trunk revert to it's original state prior to the test being invoked.

Parameter	Range
Tone frequency	Currently only supports 1004 Hz.
Tone power level	-60 to 0 dB
Test Duration	1 to 240 seconds

40.5 MWTSwap frequency error message

This feature supports the generation of a tone frequency of 1004 Hz. If a crafts person enters any other frequency (1005 Hz in the example below) the following error message will be provided:

```
MWTSwap  f 1005
USING DEFAULT POWER LEVEL (0 DB)
USING DEFAULT DURATION (60 SECS)
Action not supported - invalid frequency entered.
Frequency is currently restricted to 1004 Hz for MWTSWAP command.
```

Other command level errors are documented in the CI section of this feature documentation as well as applicable Nortel NTP documentation.

40.6 Hardware Requirements or Dependencies

AudioCodes Media Server 2000 Series (MS2010, MS2020)

40.7 Software Requirements or Dependencies

This functionality will be available in SN09.

40.8 Limitations and restrictions

1. Tone frequency generation limited to 1004 Hz..
2. Loss measurement requires presence of Milli-watt tone. AMS will provide loss measurement data if 1004 Hz. tone is received. If no tone is present or if tone received is not 1004 Hz. the craftsperson will be alerted with an informational message of “No Tn” on the MAPCI display in place of the loss reading.
3. 32 Simultaneous MWTSwap commands can be conducted per AMS.
4. In SN09 only H.248 and TGCP ISUP and OP/ES PTS trunk types are supported for the MWTSwap command. All other PTS variants and PRI trunk types are blocked to prevent the command from being run on them.
5. PTS OP/ES trunk support is available on H.248 and TGCP based gateways.
   - TGCP OP trunk limited to OG and 2W non-verification trunk. This means that an OP PTS trunk data filled on a TGCP gateway with a direction of IC or 2W with an operator mode of either “verification”(VF) or “combined_verif”(CV)is not supported and blocked at the TTP level. Operator mode can be located in table TRKGRP, field Mode.
   - TGCP gateway (Nuera) support is limited to BTX-4K gateway, the BTX8 and BTX21 gateways are not supported.
   - MWTSwap command execution on supported GWC PTS trunks is recommended on trunk in a manual busy state.
   - MWTSwap command on a trunk in an idle state is supported with the following qualifications:
     - CS2Kc to CS2Kc testing is fully supported.
     - CS2Kc to PSTN requires that the PSTN trunk perform a “Loss” command first, followed by the CS2Kc MWTSwap command.
   - MWTSwap command on a trunk in the RMB state is supported with the following qualifications:
     - CS2Kc to PSTN must have the MWTSwap command complete before releasing the PSTN trunk connection to avoid trunk state mismatches between switches.

40.11 T105 NT Responder Variant Support

The purpose of this section is to reference an additional part of this feature to provide the additional sub-test called “NT” to the T105 responder test capabilities of the AudioCodes Media Server 2000 Series (AMS) products. Today, the AMS currently supports the Nortel standard T105 test which is comprised of the following sub-tests:

a. L - Two-way loss measurement at 1004 Hz. and 0 dBm.

b. N - Far-end noise measurement with C-msg filter.

c. RN - Near-end noise measurement with C-msg filter.

d. LSC - Far-end loss self check with 1004 Hz. and 0 dBm.

e. NSC - Far-end noise self check with C-msg filter.

This support is made available for the Compact CS2K and non-hybrid CS2K configurations in which there is no ISM/MTM present which houses the traditional DMS test trunk hardware. The AMS provides a limited replacement for trunk testing to the ISM/MTM in these configurations.

The “NT” test is defined via the AT&T Technical Advisory No. 17 section CB106 as:

NT - Two-way noise measurement C-msg filter with tone at 1004 Hz. and -16 dBM.

The AMS provides the “NT” sub-test to the T105 responder functionality in the AMS. A far-end switch signaling to perform an “NT” test as a part of aT105 request can now be handled by the AMS. No development was required by Nortel for this feature. All development effort was performed by AudioCodes. The AMS support for the “NT” sub-test is limited to the responder or terminating side. A T105 test originating on an AMS will not request an “NT” sub-test.

41: Functional Description (FN): A00009204

41.1 Feature name and Feature ID

Feature A00009204 - Siren Call Agent Customer Visible Capacity Tools

NOTE: Siren is not the official name that will be used; an official name has not yet been approved.

41.2 Description

This feature covers the changes required to the Customer Visible Capacity Tools for the SOS Call Agent blade on Siren. The Capacity Tools covered by this feature are:

- CAPCI tool
- CAPACITY MAP levels

41.2.1 CAPCI CI Command

The following figure is a prototype of the output of the CAPCI CI command.

Figure 1 CAPCI Command Output

```
>capci
CAPCI -- 2004/12/13 12:42:24.018
CATMP/HR UTIL ENGCATMP ENGLEVEL MAXCATMP SYNC OVRLD IDLE COMPLEX
 1200000  50%  2400000    BELOW  2600000 +HOT   OFF  YES    1140
```

```
>query capci
CAPCI -- Display status of switch activity
Parms: [<option> {PARMS,
                  SCHEDMAP,
                  ALL}]
```

The output of the CAPCI ALL CI will output all the options available for CAPCI. The order of the ouput is CAPCI + SCHEDMAP + PARMS.

The following figure is a prototype of the output of the CAPCI ALL CI command.

Figure 2 CAPCI ALL Command Output

```
 >capci all
CAPCI -- 2004/12/13 12:42:24.018
CATMP/HR UTIL ENGCATMP ENGLEVEL MAXCATMP SYNC OVRLD IDLE COMPLEX

Term	Description
New term	Definition

42: Functional Description (FN): A00009207

42.1 Feature name and Feature ID

A00009207: DPT Trunk Testing Support

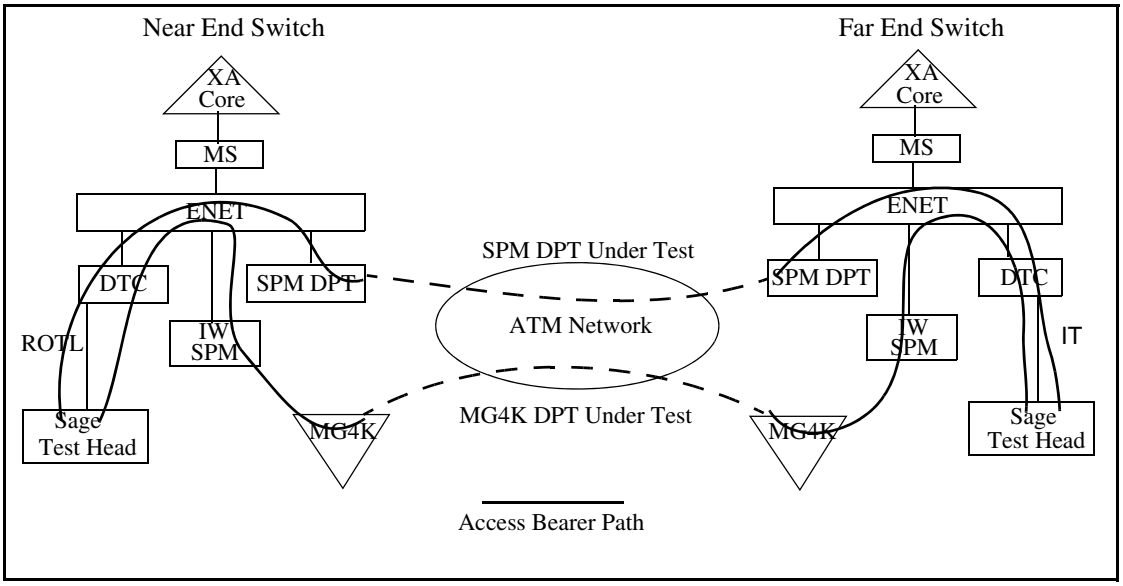
42.2 Description

This activity enhances the Digital Remote Office Test Line (ROTL) trunk interface to allow for the selection of a DPT node and Terminal Identifier (TID) if that DPT is hosted by a Spectrum Peripheral Module(SPM) or MG4K. In addition this feature allows the customer to select which SPM or MG4K to direct all incoming DPT test calls.

Digital ROTL is an existing DMS feature to remotely test trunks via a digital, four wire, E&M trunk. This CAS trunk interface permits a test head to be connected to the CS2K and, via a maintenance dial plan, select an outgoing trunk to be tested. A test head is connected to the CS2Kby a T1, on which several channels are provisioned with a ROTL trunk type. Test calls can then be outpulsed from the test head over the ROTL trunk members using a defined maintenance dial plan which instructs the CS2K software to select an outgoing trunk circuit and generate a test call to the far-end switch. A connection is then established between the test equipment and the trunk circuit being tested. Once all connections have been made the test head conducts the desired trunk test.

This feature enhances the Digital ROTL functionality to permit test connections over DPTs hosted by an SPM DPT or MG4K. The customer will be able to directly select the DPT group, node and TID to test.

Figure 1 Configuration Diagram



42.3 Digital ROTL Origination Feature Description

A test head in conjunction with the Digital ROTL feature permits the selection of an outgoing trunk to test via a maintenance dial plan outpulsed into the switch over a T1 interface. The group of digits in the dial plan which identify the outgoing trunk is known as the Port Identification Number. The current Digital ROTL Port Identification Number for TDM trunk selection is defined as the following:

KP + Test Line Id + ADNUM + Trunk Member + Testline Number + ST

KP - Key Pulse digit
Test Line Id - the code of the desired test (e.g. 05 = ROTL_105 testline id)
ADNUM - value from table CLLI represents the trunk group to be tested
Trunk Member - Member of the trunk from table TRKMEM
Testline Number - DN being outpulsed to the far end switch
ST - Stop or cut-through digit

With the introduction of DPT support by this feature, the existing TDM Port Identification Number portion of the maintenance dial plan is modified to select based on node and terminal number rather than trunk member. The new Port Identification Number will be defined as the following:

KP + Test Line Id + ADNUM + Node + Terminal + Testline Number + ST

KP - Key Pulse digit

Test Line Id - here new ids will be defined which will indicate trunk selection via the new node and terminal dial plan (#80 ROTL_100, #82 ROTL_102 and

#85 for ROTL_105)

ADNUM - ADNUM from table CLLI represents the trunk group the DPT terminal will be assigned to.

Node - the node which the DPT terminal is allocated

Terminal - the DPT which will be tested

Testline Number - DN being outpulsed to the far-end switch

The CS2K software will parse this new Port Identification Number and a selection of the desired outgoing DPT terminal will be performed. A connection between the selected DPT terminal and the test head will then be made. Once established the desired trunk test will be performed by the test head.

42.3.1 Find the node number of the SPM

The NODENO command provides the number of the node to dial for testing the outgoing call. The command also prints a reminder of the valid DPT terminal number range for the SPM. The valid terminal ranges are:

- DPT SPM: 1 to 2016
- MG4000: 2079 to 4094

42.3.1.1 Finding the node number

At the MAP terminal

1. Access the DPT info debug tools by typing
   ```
   >dptinfo
   ```
   DPTINFO:

Enter the node number command

```
>nn node_type device_class device_no
```

Note: The short form for the nodeno command is "nn". where
node_type--for any SPM, node_type is "spm"
device_class--for any SPM, device_class is "spm"
device_no is the SPM number found in table MNMODE.

Example:

```
> nn spm spm 1
NODENO=70
This node has DPT terminals 2079-4094
>
```

42.4 DPT Test Call Termination Feature Description

In conjunction with the design to provide DPT test support via the Digital ROTL interface, incoming DPT test calls will have the capability to be routed to a desired DPT node. This selection will be data fillable, and once set, all incoming DPT calls flagged as a test call will terminate on the provisioned SPM (either DPT SPM or MG4K).

42.4.1 New office parameter DPT_BICC_TEST_NODE

This activity introduces a new office parameter, DPT_BICC_TEST_NODE in the table OFCVAR which will identify the particular node to which all incoming DPT test calls will be routed to. This office parameter contains two fields, first PMTYPE and the second is SPM node number. Currently, the implementation of this office parameter will be limited to only the SPM node type. In addition, a check is place to ensure that the node number entered is supports DPT.

Note: During an ONP, if this new parameter exists in a previous software load, it will be propagated forward. If the office parameter does not exist in the previous load, the entry will be created in table OFCVAR with the default values of NIL_PMTYPE and '0'.

42.4.2 Set the CPC (Calling Party Category) in the ISUP IAM Message

A DPT test call IAM (Initial Address Message) initiated by the Digital ROTL feature is being modified to set the Calling Party Category (CPC) field to ISUP_CPC_TEST_CALL. At present this CPC field is set to the default of CPC_UNKNOWN. The CPC field will be used to identify if an incoming DPT call is considered to be a test call.

42.4.3 Move the incoming DPT Test Call to the provisioned terminating node

The incoming DPT test call will be moved to the desired SPM node based on the following:

- The call will be identified as a test call via the CPC field in the IAM message of ISUP_CPC_TEST_CALL.

- A look-up will be performed on the office parameter DPT_BICC_TEST_NODE and the provisioned SPM node will be returned.

- The incoming test call will then be moved to the desired node.

Note: Provisioning a desired terminating node effects test calls generated via the MAPCI;DPTTRKS level OP (Outpulse) command. Since a test call associated with this command sets the CPC of the IAM to ISUP_CPC_TEST_CALL.

42.5 Hardware Requirements or Dependencies

This feature enhances the existing Digital ROTL interface for trunk selection. A test head is required to perform the actual trunk test.

42.6 Software Requirements or Dependencies

Core: SN09 or greater.

SOC option BAS00050 56Kb/sTrk Tst prt must be activated.

42.7 Limitations and restrictions

1. The T1 interface to the test head equipment will not be supported on an MG4K node type because the MG4K does not currently support the ROTL trunk type.

2. This activity supports DPT terminals hosted by an SPM or MG4K. No official support is made for GWC DPT terminals. However, no enforcement will be provided by this feature.

43: Functional Description (FN): A00009208

43.1 Feature name and Feature ID

SN09 180K LINES SUPPORT - Actid A00009208

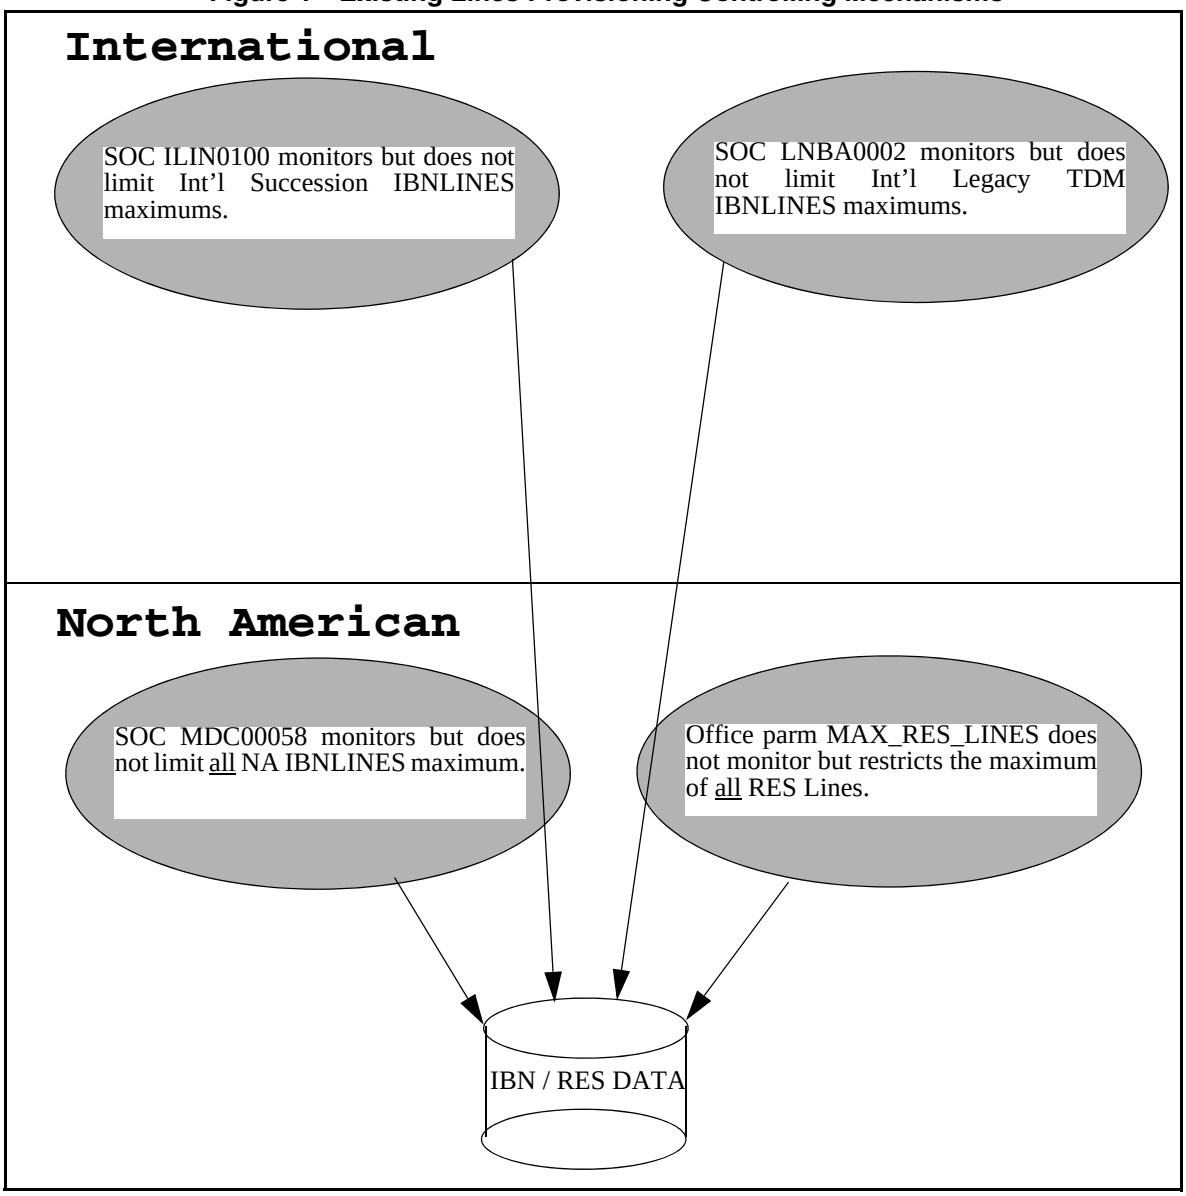
43.2 Description

The purpose of this feature is to increase the provisioning limits for lines globally from its current limit of 150k to 180k. The feature provides the ability to:

- provision a total of 180,000 RES lines for the North American market
- provision a total of 180,000 IBN lines for the International market
- perform Call Processing on each of these lines

There are no new SOCs or Office Parms introduced to activate the new provisioning limits. The capability is built into the SN09 load. The customer will use the existing mechanisms to allow provisioning of RES/IBN lines to these new limits. Refer to the following figure.

Figure 1 Existing Lines Provisioning Controlling Mechanisms



The specific SOCs mentioned in Figure 1 are soft SOCs which mean they monitor limits. Customers are allowed to go beyond their initial limit without Nortel intervention. For details on SOCs, please refer to the Maintenance and Operations Manual NTP 297-9881-500. This feature does not impact/change how these SOCs function.

The MAX_RES_LINES Office Parameter in Table OFCOPT does limit the maximum number of all RES lines provisioned. When this office parameter is changed to the new limits activation is immediate. For details on office parameters, please refer to the Office Parameters Reference Manual NTP-

297-8021-855. This feature does not impact/change how this office parameter functions.

43.3 Hardware Requirements or Dependencies

There are no hardware dependencies required to execute this feature.

43.4 Software Requirements or Dependencies

Software Dependencies:

— CORE - SN09 release or later

Firmware Dependencies:

— None

43.5 Limitations and restrictions

This feature is applicable to:

- North American and International software releases
- the CS2000 and CS2000-Compact configurations
- the AAL1 and IP solutions

This feature restrictions are:

- Does not change the Engineered maximum number of GWCs supported in an Office, currently at 60.
- Does not change the Engineered maximum number of lines supported per GWC, currently at 6400.
- Does not change or implement any new SOC controls for line capacities
- Does not increase current TDM limit of 150K lines
- Does not address the MG9000 Manager limit of 110K native lines. (ABI-based lines are not included in the 110,000 MG 9000 Manager limit)
- The current core BHCA capacity is not a limiting factor for the line access call models.
- Does not impact the ACD limit which is changing from 30K to 99,999 with SN09 feature A00009085.
- Does not increase Call Processing Feature limits:
  - — Current line service capacity limits apply (e.g., 50K Speed Call Long Lists)
  - — No more than 45% penetration of voice mail service (requiring CFW and MWT)
- Does not increase current Cable line capacity limit of 150K lines. 180K lines is possible with a combination of the current 150K Cable lines (with

a maximum of 115K MTAs when RMGC is employed) and 30K TDM or other allowable non-Cable packet lines.

43.6 Interactions

The following are the feature interactions for A00009208 feature:

- Features which A00009208 is dependant on:
  - — none
- Features which are dependant on A00009208:
  - — none

44: Functional Description (FN): A00009218

44.1 Feature name and Feature ID

Activity A00009227 - MG9KEM Data Audit Robustness

44.2 Description

MG9KEM audits can currently only be run for an entire NE, even when data mismatches exist for only a small portion of the NE data. Experience in the field has shown that subsystem data corruption (e.g VMG data mismatch on a single shelf) is the most common type of data corruption. In these types of scenarios, the customer has to wait for lengthy NE audits to run to fix issues that in reality require only a small amount of time to run.This activity will enable subsystem audits. This capability was built in from the start, but has not been enabled in previous releases. This change offers both efficiency and robustness improvements as well as enhanced usability:

- ïRobustness improvements. The EM does not have to use unnecessary database resources and strain the MG9000 with unnecessary SNMP traffic, which has been known to affect call processing performance.
- ïUsability improvements. Selective audits will allow the user to quickly fix call processing affecting data mismatches. This will translate into significantly reduced outage times if data mismatches are call affecting. Also minimizing the audit times will in turn reduce the periods in which the GUI response of the EM is sluggish because the server is busy.

44.3 Hardware Requirements or Dependencies

No additional requirements are needed for this feature besides the standard MG9000 EM and the MG9000 Gateway.

44.4 Software Requirements or Dependencies

This is a standalone feature and has no special requirements or dependencies.

44.5 Limitations and restrictions

Subsystem audits will only be allowed for non-scheduled audits only.

44.6 Interactions

45.1 Feature name and Feature ID

Activity A00009227 - NPM Robustness

45.2 Description

The NPM Robustness feature addresses areas for improvement in the Network Patch Manager. Following is a list of items that this feature will provide:

- A New log will be provided as part of the NPM Customer logs indicating whether a GWC image was successful or not.
- Six new system defined reports will be added to the NPM as a result of this feature:
    - DEVICEINFO - lists the devices in the office, the date the devices registered, the loadname in the device and the date the load was discovered in the device.
    - LASTAPPLYACTION - A list of the patch, device, status and description of why the apply attempt failed for this patch device relationship.
    - PFRSSETTINGS - Lists the PFRS Dropbox, PFRS userid and status of if the delete patches is turned on.
    - SYSTEMPLANSETTINGS - Lists all the system plans in the office along with the tasks, enable status, and schedule for each plan
    - OFFICEINFOSETTINGS - Lists office information. Currently, only the GWC Auto imaging enabled setting is available in this report.
    - GWCLOADIMAGEREPORT - Lists the imaged load, the patches contained in the load, the time the image was taken and a list of patches available in the office that are not contained in the image.

All of these reports will be included in the inform report that is generated via the PFRSGENREPORT task in the NPM.

- The NPM CLUI will be able to accept patchids in lower case, upper case or a combination of thereof; except for one command, q PATCH.
- The majority of the NPM CLUI commands will be changed to ensure command naming consistency for commands that provide similar types of functions.

- A new alarm will be raised on the Media Gateway 9000 GUI (MG9K EM) after applying or removing a “restart required” patch to any of the Media Gateway 9000 patchable cards.
- The “restart required” patch alarms at the MG9K EM will be lowered after restarts are performed on MG9K patchable cards.
- Logs and alarms for “restart required” patches will be provided during application or removal of the patches.

46: Functional Description (FN): A00009230

46.1 Feature name and Feature ID

Activity A00009230 - CS2000 Session Server Linux Support

46.2 Background

This activity provides the Linux support for the CS2000 Session Server in the SN09 / MCP9.0 release.

46.3 Overview

This feature continues the Linux porting work started by feature FTR399 in MCP3.1. In that feature, the MCP3.1 MCS-5100 (enterprise) system was ported to two IBM platforms: the IBM e-Server series x306 (small system) and BladeCenter (large system), both of which are based on Intel hardware. That porting effort based the MCP-5100 Linux systems on a distribution from RedHat called RedHat Enterprise Linux (RHEL) Application Server 3 (AS3), update 1.

In MCP9.0 the MCP product is being included into the CS2000 platform as the CS2000 Session Server, providing SIP functionality for the CS2000 platform. As the CS2000 platform is targeted for the carrier market, the porting effort focuses on the porting of the CS2000 Session Server onto carrier-class (NEBS certified) hardware.

The selected Linux distribution for CS2000 Session Server in SN09 / MCP9.0 remains RHEL AS3 (Update 3). Please refer to section Linux Operating System / Distribution3.1.1 for more information.

The network elements of the MCP architecture which are included for the CS2000 Session Server include the following, and are given the highest priority by this feature:

- Database
- System Manager
- SIP Session Manager
- Provisioning Manager

The following MCP network elements are also ported, but are given second priority as they are not required for the CS2000 Session Server:

- Fault Performance Manager

- Personal Agent Manager
- Accounting Manager
- IP Client Manager
- UFTP Server
- H.323 Gatekeeper

The following MCP network elements are not included in this porting feature:

- RTP Portal
- Audiocodes Gateway
- Media Application Server
- UAS Audio Server

The hardware platform chosen for the CS2000 Session Server is the HP CC3310 NEBS-compliant rack-mounted server.

46.4 Linux Operating System / Distribution

The selected Linux distribution for CS2000 Session Server in the SN09 / MCP9.0 release is RedHat Enterprise Linux Advanced Server 3 (RHEL AS3), Update 3. This distribution was used in earlier Linux porting work for MCP products and thus provides the least risk for this release of CS2000 Session Server.

Future CS2000 Session Server releases will deliver on NCGL (Nortel Carrier Grade Linux). Several basic requirements need to be satisfied before this can occur, however, including:

- Support for the Sun 1.4.x series of JVM must be available.
- Support for the Oracle 9.2.0.5 DBMS.
- Support for the SunONE web server must be available. An alternative to this is the transition, for the MCP product, away from SunONE to Apache Tomcat.
- SMP (Symmetrical Multiprocessor) support for the target hardware (IA32) must be provided.
- Transition to the 2.6 kernel to leverage enhanced threading (NPTL, Native Posix Thread Library), scheduler performance, and SCTP stack.

46.4.1 Platform Hardware

The hardware platform chosen for the CS2000 Session Server in this release is the HP CC3310 server. This is a NEBS-compliant rack-mounted server. The following table provides the key hardware characteristics of this platform.

Table 2: HP CC3310 (Model A9862A) Specifications for CS2000 Session Server

Item	Description
Processor	2 Xeon @ 2.4 GHz each
Memory	4 GB
L2 Cache	512 KB
Hard Disk	2 x 73 GB 15K Ultra 320 SCSI, hot swap
Optical Drive	CD-RW / DVD-ROM
Ethernet	4 x 10 / 100 / 1000 Base-T
RAID	Software RAID
NEBS	Level 3
Power	DC, redundant
Form factor	Rack
Dimensions (H x W x D)	3.45" x 17.11" x 20" (2U high)

46.4.2 CS2000 Session Server Product Configuration

There is only a single logical MCP configuration which is supported for CS2000 Session Server. Figure 1 CS2000 Session Server Product Configuration1 shows the mapping of the major MCP system components onto CC3310 server machines. The base system consists of four HP CC3310 servers deployed as two redundant pairs. Server pair 1 hosts the following MCP elements:

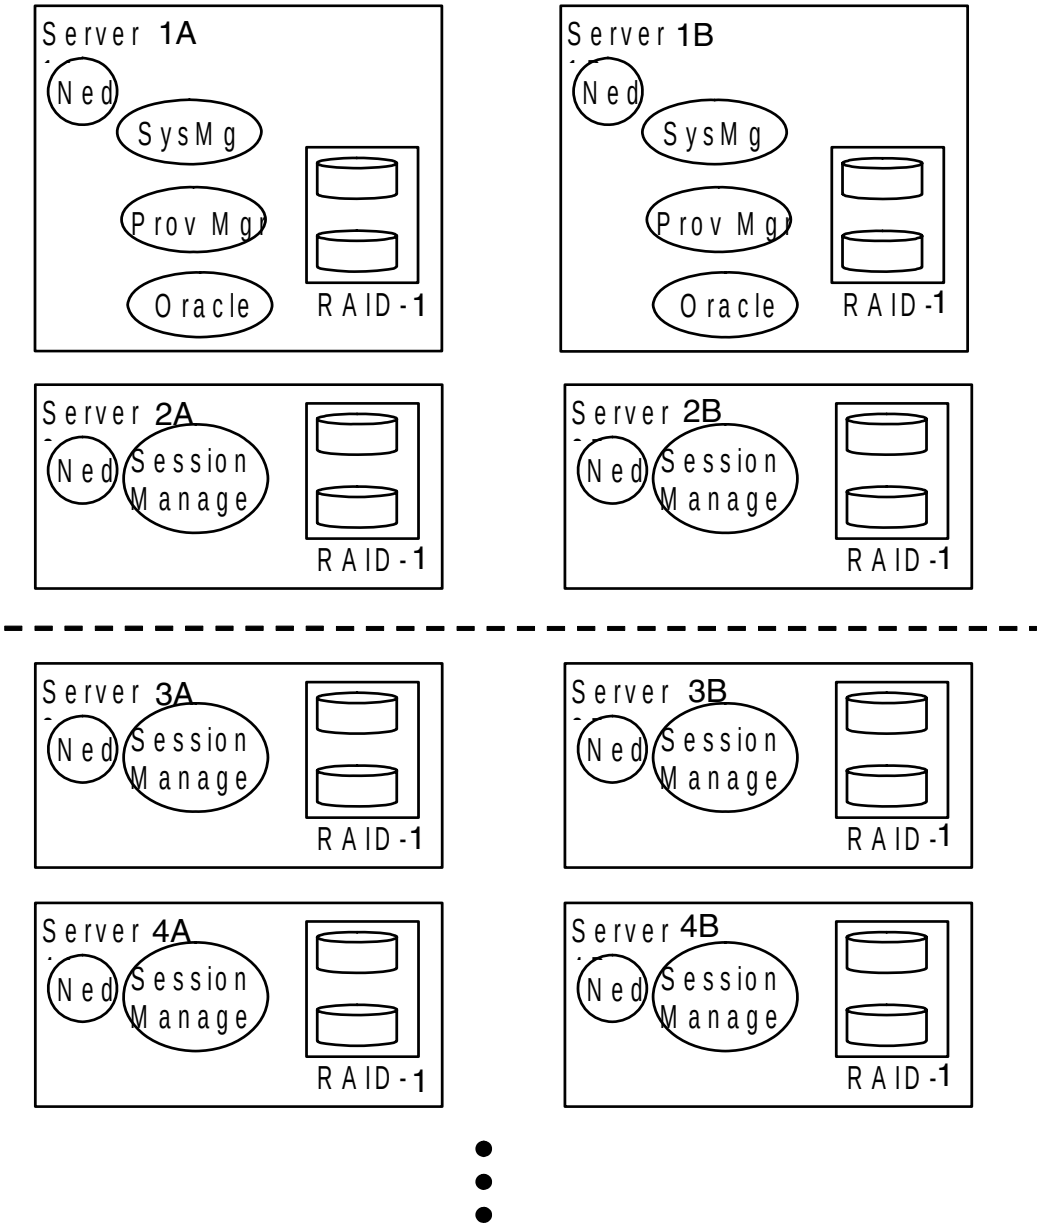
- SM (System Manager). This component configures, monitors, and maintains all MCP-based network elements. It also serves as the Fault-Performance Manager (FPM) which formats, stores, and forwards logs, alarms, and OMs. The backup system manager runs in a cold standby mode.
- Provisioning Manager. This network element provides the main provisioning interface into the system. It runs the SunOne web server through which client browsers connect to perform system-level provisioning actions. The provisioning managers run in load-sharing mode. Scaling of the Provisioning Manager is through additional provisioning managers.
- Database. This component provides the storage of persistent data for the system and is currently built on the Oracle DMBS. Redundancy is achieved through Oracle replication.
- Ned (Network Element Daemon). Ned is a process which runs on each server machine and which oversees the lifecycle of the MCP software components and cleans up logical network interfaces (where applicable) should a component die an unnatural death.

Server pair 2 hosts the following MCP components:

- SIP Session Manager. This network element runs the main SIP application portion of the CS2000 Session Server. The backup SIP Session Manager runs in hot standby. Scaling is through additional pairs.
- Ned. This is the same as previously discussed.

The server machines and components shown above the dashed line in Figure 1 CS2000 Session Server Product Configuration illustrate the base system (mandatory components). The server machines and components below the dashed line indicate an example of optional server machines and hosted MCP components used in system scaling. There is only a single (redundant pair of) SM / database / Prov in the system.

Figure 1 CS2000 Session Server Product Configuration



46.4.3 Installation and Commissioning (I & C)

There are four fundamental activities involved when performing an I&C on a CS2000 Session Server machine.

- Making BIOS-level settings and adjustments.
- Base-level software installation.

- Installation of the Oracle database on server machines which host the Database Module (if appropriate).
- Installation of MCP software loads in preparation for system deployment (if appropriate).

After completing the above steps, the system is then ready for the deployment of the MCP components and network elements.

46.4.3.1 BIOS-Level Settings

The CC3310 is an Intel based machine and comes with a BIOS familiar to any user who has previously used a PC or other Intel-based machine.

BIOS-level changes required during an I&C for this platform are TBD.

46.4.3.2 Base-Level Software

Installation of base level software typically includes the partitioning of disk drives, installation of the operating system and associated device drivers, installation of base system commands and utilities, and installation of MCP specific software packages used to support the MCP components and network elements to be deployed following the I&C process.

The core I&C mechanism used for this step of the I&C process is based on the RedHat kickstart framework.

The following basic steps are followed for this step of the I&C process:

1. Insert installation CD and reboot or power up the machine. Note that only a single CD is required for installation of the base system.
2. A Customer Information Questionnaire (CIQ) session is executed. The purpose of the CIQ is to specify key base-level configuration items for the server such as host IP settings (address, mask, gateway), the type of server being configured, IP addresses of other key machines, and time zone information.
3. The automated install of all the software mentioned at the start of this section is performed (no user intervention).
4. The system is rebooted.

The approximate installation time for base level software on the CC3310 platform is TBD minutes (expectation is roughly 15 minutes).

Note that this I&C mechanism is also used during system restore operations (recovering catastrophic server failures).

46.4.3.3 Oracle DBMS

If a Database Server machine is being I&C'd, the Oracle database is installed after the base level system install is finished. Installation methods for the

Oracle database follow the same CD install methods as is used for Solaris based MCP machines.

The approximate installation time for the Oracle DBMS on the CC3310 platform is TBD minutes (expectation is roughly 30 minutes).

46.4.3.4 MCP Software Installation

If a System Manager is being I&C'd, the MCP software load is installed after the base level system install is finished. Installation methods for these software loads follow the same CD install methods as is used for Solaris based machines.

The approximate installation time for the MCP load on the CC3310 platform is TBD minutes (expectation is roughly 5 minutes).

46.4.4 Backup and Restore

The objective of the backup and restore strategy is to provide a mechanism to completely recover a server machine, or a whole system, in the case of a catastrophic failure. A catastrophic failure typically means the loss of both disk drives (loss of all configuration).

The exact mechanism used for a backup and restore depends on the configuration of the server machine (see Figure 1 CS2000 Session Server Product Configuration). The following subsections outline specific backup and restore mechanisms for each configuration.

The backup and restore strategy employed here places no requirement for the use of tape drive units. In the cases where data must be persisted to external media, the customer has a choice on how this must be performed. Although a tape drive is one option, customers may also choose to perform this off-system storage through the use of CD-R's, CD-RW's, DVDs, or any other permanent external media.

46.4.4.1 Base System (Any Server Configuration)

When restoring a server machine, the first step in the process is always to recover the base system. Central to the restoration of the base of the system is the re-install and commissioning (re-I&C) of the machine from the original media. These server machines are relatively static in their configuration. Other than MCP component software, these machines do not undergo any other software installations which deviate from the original installation. Any base-level patches applied to an installed system are typically included in a new release of the I&C CD-ROM which is delivered as part of the maintenance release (MR). Re-installing from this new CD eliminates having to re-apply incremental patches from previous MRs.

This step of the restoration process, therefore, means the application of the I&C steps outlined in section BIOS-level Settings, if required, and section

Base-Level Software. The backup process for the latter (base system software) simply means the persistence, onto external storage, of the critical configuration data gathered during the CIQ (Customer Information Questionnaire) of the original I&C for that server machine. The restoration of the base level software, therefore, is optimized by making available this saved configuration information to the I&C mechanism during a restore, thus optimizing the time involved in the restoration process and drastically reducing the possibility of configuration errors.

46.4.4.2 SM + DB + Prov Configuration

All configuration information for the System Manager and Provisioning Managers are persisted in the database. There are no special actions required to perform backups of these components. For the database component, a nightly cron job executes on the hosting server machine, and which takes a snapshot of the primary database, storing it on the local hard drive. This backup image is then manually transferred to a remote backup server using secure FTP (SFTP). At the remote machine, this file is then written to persistent external media such as a CD-ROM, DVD, or tape drive. This protects against failures of the backup server. This storage mechanism is beyond the scope of this feature.

The following is the general procedure followed to restore a server machine configured with these components. This procedure assumes that the mated (redundant) server machine has taken over service for all of these components.

- The base level system is restored as described in section “Base System (Any Server Configuration).”
- The Oracle DMBS is installed using standard installation methods for I&C, but making use of the persisted configuration settings from the initial install (similar to how the base level software configuration systems are persisted).
- The MCP load is placed onto the server machine.
- The Database component is deployed manually using scripts from the MCP load. The “No files” option is specified such that no attempt is made to bring the database into service, or to start a database sync operation.
- A database re-sync operation is run to bring the two databases into sync and to allow the primary to take over execution (if this server machine in fact hosts the primary database).
- The System Manager component is deployed manually using scripts from the MCP load. The System Manager is left in the non-running state as the mate System Manager is currently running on the redundant machine.
- If necessary, the backup System Manager is taken down, and the primary System Manager is brought up.
- From the Management Console, the Provisioning Manager is re-deployed.

At this point, the server has been restored to full operation. In the event that both servers hosting these components have failed, the same procedure is followed above, except for the recovery of the first (primary) database. Instead of recovering the database contents from a re-sync operation, the snapshot from the last backup is transferred to the machine and local scripts are executed to restore the contents from that snapshot.

46.4.4.3 Session Manager Configuration

The restoration of the Session Manager server configuration shown in Figure 1 CS2000 Session Server Product Configuration is a simpler process than that required for the SM / DB / Prov configuration described earlier. The fundamental steps include:

- Restore the base system software as described in section “Base System (Any Server Configuration).”
- From the Management console, deploy and start the component(s) found on that server.

46.4.5 System Management

46.4.5.1 Core System Management

The core OAM (Operation, Administration, and Management) mechanism of the CS2000 Session Server remains as it is in MCP4.0. The System Manager (SM) continues to provide the following key management functions:

- Deploying, undeploying, starting, and stopping CS2000 Session Server network elements such as the Provisioning Manager and Session Manager.
- The collection and reporting of logs from the various network elements.
- The collection and report of Operation Measurements (OMs) from the various network elements.
- The collection and reporting of alarms from the various network elements.

The SM continues to provide a WSDL-based management interface through which clients such as the MCP Management Console can communicate. The default Management Console, accessed through the Apache Tomcat web server, remains.

46.4.5.2 Northbound Network Management System (NMS) Interfaces

A number of north-bound NMS interfaces are used with the CS2000 Session Server including:

- Management console
- Open Provisioning Interface (Bulk Provisioning)
- Secure FTP / SSH
- Nortel Reliable MIB.

46.4.5.3 Remote Server Management

Remote server management refers to the ability to power down, power up, and reset CS2000 Session Server network elements remotely from the System Manager. The typical interface for performing this function is via the CS2000 Session Server Management Console which interfaces to the System Manager via the WSDL-based OMI interface.

This capability is not a requirement for CS2000 Session Server in this release and is therefore not implemented for the CC3310 platform.

46.4.5.4 Serial Console

Serial console access refers to the ability to log into the system console through the serial port of the server machine. This is required in the event of loss of access through normal SSH login mechanisms, and for security reasons.

Connectivity is achieved by attaching the external serial port of the CC3310 to a terminal server. Access to the terminal server is typically through a management LAN and is therefore protected from general access.

The system console of the kernel is made available to the serial port both at I&C and during normal system run time. Serial console login is enabled for all provisioned users (“root”, “sysadmin”, and “nortel”).

Providing serial console access during I&C allows multiple systems to be I&C’d simultaneously from one remote station (e.g., PC).

46.4.5.5 SSH / SFTP

Telnet and FTP access to server machines is disabled as part of OS hardening (refer to that section). Instead SSH (Secure Shell) and SFTP (Secure FTP) access are provided.

46.4.6 Application-Level Components

46.4.6.1 SIP Stack

In this release of the CS2000 Session Server, the SIP stack is being migrated from Java to the Radvision C++ stack. For application components which are written in Java, JNI is used to interface to the C++ stack. The integration of this stack into the CS2000 Session Server is outside the scope of this feature and is being performed by [3].

46.4.6.2 Web Server

The CS2000 Session Server makes use of two different web servers.

- The Apache Tomcat web server is used to gain access to the System Manager’s Management Console, and makes use of the Java Web Start mechanism.

- The SUN Microsystem's SunONE web server is used on the Provisioning Manager. This web server is actually installed during I&C on all server machines but is only enabled on the machines which are deployed with the Provisioning Manager. Feature FTR460 [6] enabled SSL for the SunONE web server on Linux and provided a default Nortel self-signed certificate. This feature completes the integration of this functionality onto the target Linux platform used by this feature.

46.4.6.3 Java Virtual Machine

The CS2000 Session Server uses version 1.4.2_06 of the Sun MicroSystem's JVM.

46.4.7 IPSec

IPSec is used for encrypted connections (using transport mode) between the following components:

- RTP Portal and database server machine.
- RTP Portal and the System Manager (SM).
- RTP Portal and Session Manager.

Under the target Linux distribution, the IPSec policy database and encryption is performed within the kernel. The "ipsec-tools" RPM package is a BSD-licensed open source package which provides the following capabilities (refer to [7] for more information on open sources licenses):

- "libipsec", a PFKeyV2 library
- "setkey", a program to directly manipulate policies and SAs (Security Associations)
- "raccoon", an IKEv1 keying daemon

The API-level integration of IPSec into the CS2000 Session Server is implemented by [5]. This feature (A00009230) integrates the work of [5] into the I&C of the target systems.

46.4.8 Database

The database implementation used for CS2000 Session Server is Oracle 9i.

46.4.9 Fault Tolerance

There are several key areas regarding fault tolerance which are relevant to this feature. They are included in the following subsections.

46.4.9.1 Network (Ethernet) Interfaces

As with prior MCP releases, the dual ethernet interfaces to the server machine are grouped together in a port-bonded relationship using the port bonding driver functionality built into the linux kernel. The bonded interfaces are arranged in an active-backup mode. Upon initialization of a healthy system,

eth0 is made the active interface and eth1 the backup. When an active interface fails, the other interface takes over and remains active until it fails or the system is once again restarted.

Failure detection is through “miimon” which monitors link status. Upon failure of the link (e.g., link pull, failed network interface), failover actions are automatically taken by the port bonding driver, and remain unknown to application layer software.

46.4.9.2 Application Fault Tolerance

Check pointing and hot standby is added by [4] to the Session Manager’s fault tolerance functionality. The remainder of the MCP system’s application-level fault tolerance functionality remains the same as in prior MCP releases.

46.4.9.3 RAID (Redundant Array of Independent Disks)

RAID Level 1 (disk mirroring) is a hard requirement for the CS2000 Session Server machines. RAID-1 allows the continued operation of the system in the event one of the disk drives should fail.

The HP CC3310 server platform does not provide hardware RAID natively on the machine. Rather, an optional RAID controller (PCI card) from Intel is available, at additional cost, to provide this function. However, this additional cost and NEBS PI testing requirements make it infeasible to include this optional card into the product at this time. Given that the disk I/O traffic is relatively moderate for this type of system and does not pose a bottleneck, software RAID is an acceptable alternative and is implemented by this feature. Note, however, that software RAID requires a post-I&C period where the system synchronizes the two hard drives. During this time, the system runs in a degraded (non-protected, CPU overhead) mode.

This feature implements RAID-1 using the RAID functionality provided by either the “raid-tools” or “mdadm” GPL packages.

46.4.10 Kernel Features

46.4.10.1 SMP (Symmetric MultiProcessing)

The HP CC3310 platform uses dual 2.4 GHz Xeon processors. The kernel of the target Linux distribution fully supports SMP to allow the CS2000 Session Server to fully leverage this capability.

46.4.10.2 Hyper threading

The Xeon processors used on the HP CC3310 platform include support for hyper threading. The kernel of the target Linux distribution fully supports hyper threading to allow the CS2000 Session Server to fully leverage this capability.

46.4.10.3 NPTL

The target Linux distribution implements the NPTL (Native Posix Thread Library) enhancements which provide a much improved thread model than found in previous Linux distributions.

46.4.10.4 OS Hardening

This feature includes the changes required to provide a secure (hardened) system which is resistant to malicious or inadvertent attacks. These changes are implemented through a combination of elements including installation of software packages (e.g., ssh) and patches, changes to configuration files, and changes to system settings in the late stages of the automated installation procedure.

Areas which are affected by this hardening exercise include:

- Install patch for security and bug fix
- Minimize services
- Access control and authorization
- Logging
- Kernel tuning
- File and file system security
- Manage account on the server
- Secure Shell SSH
- Other miscellaneous actions

Please refer to [1] and [2] for a detailed discussion of the elements which go into the hardening of a system, and which are employed as part of this feature.

46.4.11 SCTP

The CS2000 uses SCTP as the transport protocol for the NCAS (Non Call-Associated Signalling) link between the CS2000 core and the CS2000 Session Server. This link is used for the relaying of line-maintenance related signalling.

The kernel of the target linux distrution does not currently support SCTP natively. The implementation of SCTP is therefore based on the open-source reference standard for SCTP available from “sctp.de” [8].

46.4.12 Software Management

46.4.12.1 Software Delivery

The processes for the naming, building, bundling, vaulting, and delivery of the CS2000 Session Server follows the same methods as used in prior MCP releases. Loadnames are based on MCP 9.0 version naming.

46.4.12.2 Software Upgrade and Maintenance Releases

The process to bring a system to a running state where it is able to process traffic involves two different stages of software installation. The first stage is the I&C of the server machine as is described in section “Base-Level Software.” The second stage is the deployment of the MCP component software onto the appropriate target machines.

Applying software updates and maintenance releases to the MCP component modules (second stage above) is performed in the same fashion as is done for MCP components on prior Solaris-based MCP systems. This essentially involves the creation and vaulting of new CD images of MCP software loads, distributing and installing these loads to customer systems, and using the system management console to apply the updated software to the necessary server machines.

Due to I&C differences, however, the methods for applying software upgrades and maintenance releases to the base platform are different for Linux based systems. The following outlines the steps performed for maintenance releases to this base software:

- At some point, it is determined that a new release of the base server software is required. Examples of such changes include patches to the base Linux kernel, corrections to MCP base software, and new base system utilities.
- Each of these updates is built into an RPM (RedHat Package Manager) package.
- The set of these RPM packages are collected and an MR (Maintenance Release) README file is created with instructions on how to apply the changes to an existing system.
- An ISO CD image is created with this update and is vaulted in the Nortel software distribution databases.
- A new I&C CD is created with these same updates included and is similarly vaulted.
- Both the MR and new I&C CD are delivered, or downloaded, to the customer site(s).
- The MR CD is used to apply the updates to any existing machines.

In addition to the base level software, it may also be necessary to upgrade the BIOS of the machine. BIOS upgrades are typically required due to unrecognized (new) hardware and therefore are usually required during initial system I&C (where the factory-installed BIOS may be an older revision). BIOS upgrades are typically performed using bootable media where, upon boot up, a program is launched through which the BIOS flashing process is performed. These boot media are vaulted and distributed to customers in the same manner as is done for system I&C CD’s.The I&C CD is used to install

any new servers which may be required and / or to restore any existing server which may fail in the future.

46.4.13 Re-IP Serviceability

The Linux-based MCP system has the ability to be re-IP'd through execution of a local script. Prior to the re-IP, the components on the server machine need to be undeployed and re-configured. The steps to recover the MCP components are similar to the steps used to restore MCP components as described in section "Backup and Restore."

46.4.14 Third Party Software Licensing and Support

The following are the major third party software components used by this feature:

- RedHat Enterprise Linux Advanced Server 3 (RHEL AS3). This includes a number of open source packages within the distribution.
- Oracle 9i
- Sun MicroSystems Java Virtual Machine 1.4.2_06
- SunONE web server

Additional dependencies on third party software and their licensing are TBD.

46.5 Dependencies

Not applicable.

46.6 Network Engineering

A Linux-based server requires two less IP address than a Solaris server configured with the same software components. This is due to the differences in NIC redundancy mechanisms between Solaris and Linux.

On Solaris-based machines, IPMP (IP MultiPathing) requires a physical IP address per NIC, as well as a logical IP address per IPMP group. Linux based machines use port bonding in place of IPMP. The port bonding driver re-uses the same IP address for both NICs as well as the bonding interface which is created to enslave these NICs. Therefore, on a public-only machine with two NICs (the only configuration supported for Linux-based servers), only a single IP address is required.

There are no differences in IP port usage between Linux and Solaris.

47: Functional description (FN): A00009235

47.1 Feature name and Feature ID

Activity A00009235 - TLS for SIP

TLS = Transport Level Security, a security protocol that enables secure data transmission between two communicating applications.

SIP = Session Initiation Protocol

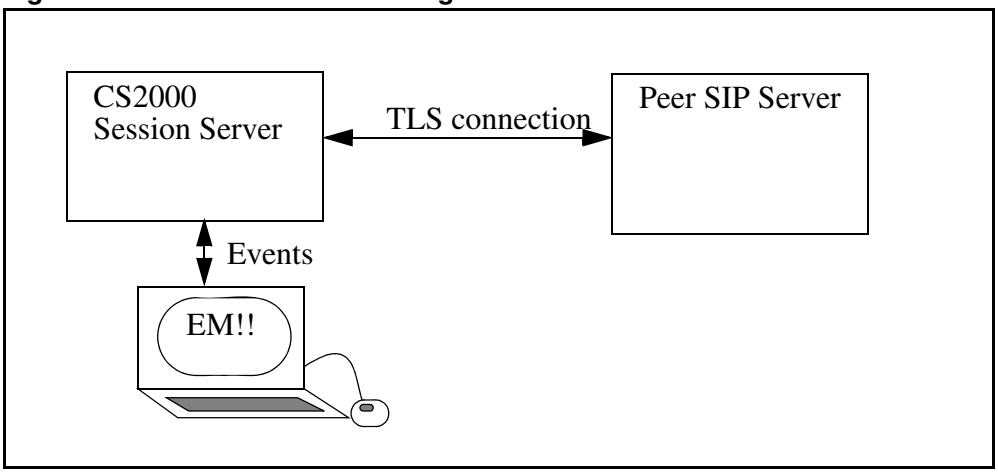
47.2 Description

The TLS for SIP feature will provide robustness improvements over the SN08 functionality, as well as provide compliance to specified Packet Cable requirements.

The peer-to-peer scenario is the focus of this feature. The peer SIP servers that the CS2000 Session Server connects to need to be authenticated, a TLS cipher must be selected, and the connection must be monitored, all to ensure the security of the connection and the validity of the messages being passed between the two peers. Most of this functionality has been delivered already, however some items remain (for example, FQDN/IP address mapping from the certificate, to ensure that FQDN's can be verified in the SIP messages).

Additional robustness improvements on the local CS2000 Session Server to alert the craft to issues in the system are required, and added flexibility to system/threshold settings are desired as well.

Figure 1 Functional Behavior Diagram



47.3 Hardware Requirements or Dependencies

No new hardware dependencies are introduced in SN09.

47.4 Software Requirements or Dependencies

This feature requires the standard SN09 load.

47.5 Limitations and restrictions

The following limitations exist for this feature:

Provisioning

- CS2000 Session Server Call Processing must be restarted anytime a new server certificate is provisioned (Call Processing is not required to be restarted if remote servers' certificates are provisioned).
- CS2000 Session Server Call Processing must be restarted for the following security parameters to take effect:
  ExitOnFailTLSInitialization
  MaxTLSSessions
  localTLSport
- Self-Signed Certificates from other servers must be data filled on the CS2000 Session Server in order to have the CS2000 Session Server recognize those certificates.
- Any Self-Signed Certificate from the current CS2000 Session Server must be data filled on other CS2000 Session Servers -- and other SIP servers in general -- in order to have the remote servers recognize those certificates.
- Restarting CS2000 Session Server Call Processing means restarting the SIP gateway application.

Performance

- Client-side session caching will be supported on the CS2000 Session Server. Server-side session-caching is already supported. However, the session cache exists only in memory. During a Dead-Office Recovery (DOR) new TLS sessions will require a full handshake.
- The maximum number of supported simultaneous TLS connections is limited to 400. The provisionable parameter 'MaxTLSSessions' controls this maximum number, and any connection attempts beyond the provisioned maximum will be rejected.

Cryptography

- Only RSA/DHE_RSA and AES/3DES ciphers will be enabled for use on the CS2000 Session Server by default. These will be the only ciphers supported by Nortel on the CS2000 Session Server. Specifi-

cally, the supported ciphers will be:
TLS1_TXT_RSA_WITH_AES_128_SHA,
TLS_DHE_RSA_WITH_AES_128_CBC_SHA,
TLS1_TXT_RSA_WITH_AES_256_SHA,
TLS_RSA_WITH_3DES_EDE_CBC_SHA,
TLS_DHE_RSA_WITH_AES_256_CBC_SHA and
TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA.

- RSA keys used on the CS2000 Session Server will require a minimum of 1024 bits. RSA keys of smaller sizes are generally considered to be vulnerable to cracking.
- AES keys used on the CS2000 Session Server will require a minimum of 128 bits.
- Imported certificates will be expected to be in X509 version 3 PEM format,, in order to be imported for use by the CS2000 Session Server.

Licensing

- Licenses apply to certain open-source code (OpenSSL, Cryptlib) that are used in the CS2000 Session Server implementation of TLS. Terms of use require acknowledgement of the various authors in customer documentation materials etc. Please see appendix for full licenses of open-source code used within this product.

Certificate

- In this activity if the certificate and key files is changed in one NGSS, during initialization the mate host will be notified. If the mate host has not been updated with the new certificate and key files an alarm will raise. The limitation here is the application is not copying the certificate and key files over the mate host and by a craft person should do it.
- If the Common Name of the certificate contains an FQDN, it must match the Remote SIP Server name as provisioned in the Remote SIP Server web page. This FQDN must be less than 64 characters in length.
- Remote SIP Server Cluster configurations in which a single Remote SIP Server has been datafilled with multiple IP addresses must ensure that the Common Name of the certificate presented from any one of the IP addresses in the list matches either the IP address of the originator, or the FQDN as presented as the name of the Remote SIP Server.

47.6 Interactions

47.7 Glossary

Term	Description
TLS	Transport Level Security, a security protocol that enables secure data transmission between two communicating applications.
SIP	Session Initiation Protocol
DOR	Dead-Office Recovery, the term used to describe the complete loss, then recovery, of an entire office.

47.8 Appendix

48: Functional description (FN): A00009239

48.1 Feature name and Feature ID

A00009239: Services for SIP Lines

48.2 Description

This feature expands the existing Message Waiting (MWT) service supported in the CS2K Core to SIP Lines.

The MWT service provides the activation/deactivation of the Message Waiting Indicator (MWI) on the line. In SIP Lines case, actual MWI is provided by the SIP Line or actual edge device (e.g. Optical Network Terminator (ONT)) when the SIP Notify message with Message Waiting header is received from the network and/or voice mail system.

The MWT service in SIP Lines case assumes that the Voice Mail is connected to Communication Server 2000 (CS2K) via existing Voice Mail connetivities (e.g. SMDI and UCD for Traditional Voicemail). The SIP Line is assigned with the appropriate Call Forwarding - Call Forward Do Not Answer (CFD) and Call Forward Busy (CFB) options.

When a call is terminated to SIP Line, the call is offered to the line. However, if end user is busy on another session/call on the SIP device or end user do not answer the call, the CFB or CFD occurs and call forwards to the Voicemail. The Voicemail as existing functionality answers the call and prompt with personalized greeting to the caller. The caller leave a message and end the call. The Voicemail sends the activation request to the serving CS2K for the SIP Line. This request is converted to a SIP Notify message by CS2K and sent to the SIP Line. The SIP Line than provide appropriate message waiting indication to the device for end user.

When end user observes the indication, make a call to Voicemail system. Upon answer, the voicemail prompts the end user for the userid and password. The end user connects to his/her voicemail box after userid and password authentication and starts listening the voice messages. When all new messages are listened by the end user, the Voicemail sends the deactivation request to the serving CS2K for the SIP Line. This request is converted to a SIP Notify message by CS2K and sent to the SIP Line. The SIP Line than remove appropriate message waiting indication to the device for end user.

48.3 Hardware Requirements or Dependencies

Not Applicable

48.4 Software Requirements or Dependencies

Not Applicable

48.5 Limitations and restrictions

The following are the restrictions and limitations of this service:

- Only Message-Waiting ON/OFF is supported in the SIP Notify message as per RFC 3842. Rest of the optional data required by the RFC 3842 are not supported.
- The existing MWT software in the CS2K only supports number upto 10 digits. This existing limitation apply to the MWT extension to SIP Lines.
- The direct communication with a SIP based Voicemail is not supported due to limitation of availability with the SIP based Voicemail during development.
- The DTMF tones required by the Voicemail system is assumed to be supported by appropriate Codec from the SIP Lines.
- This development only supports following form of the MWT service:
  - Message Waiting (MWT) option on the line.
  - Network Message Waiting (NMS) when Voicemail is networked to serving CS2K.
  - AIN (North American - NA) based MWT using AIN Update messages from Switching Control Point (SCP) to serving CS2K.
- For SIP Lines, only Message Waiting Lamp (MWL) notice is valid to datafill in the CS2K. The Stutter Dial Tone (STD), Periodic Ring Notification (PRN), etc. notice types are invalid for the SIP Lines because SIP Notify message does not allow to specify the notice type for SIP Line device. Also, the type of indication depends on the end user device in the SIP Lines case.
- Only following type of SIP Lines are supported by this design:
  - SIP Phone provided by CISCO
  - PC Client

48.6 Interactions

All existing MWT interactions works the same way with the SIP Lines. No new interaction anticipated.

48.7 Glossary

Term	Description
AIN	Advance Intelligent Network
CFB	Call Forward Busy

STD	Stutter Dial Tone
UCD	Uniform Call Distribution

49: Functional description (FN): A00009241

49.1 Feature name and Feature ID

A00009241 - NCAS and QSIP Development on CS2K SS

49.2 Description

The Non-call associated signalling (NCAS) Link on Communication Server 2000 (CS2K) Session Server (SS) platform with query SIP line data (QSIP) application feature provides a light-weight switching control point (SCP) like functionality (SCPLite). The NCAS link provides a non-call associated link between the CS2K SS and the core. At present the NCAS link is only used by the SIP Lines program for QSIP command interface (CI) command in the core to get the static and dynamic data snap shot from the CS2K SS platform related to the SIP line.

The display of the static and dynamic data is provided by QSIP CI command at CI increment.

49.3 Hardware Requirements or Dependencies

The development is on CS2K SS platform.

This activity does not require any new hardware.

49.4 Software Requirements or Dependencies

This activity uses SCTP library (SCTP.DE) developed in Germany for SCTP communication with the Core. The SCTP.DE is a generic SCTP library available from the web and it is not a NOTEL product.

The activity depends on the following two activities:

- QSIP CI Command development in the core under actid A00008556.
- OAM and GUI development in the CS2K SS platform under actid A00009028.

49.5 Limitations and restrictions

- Only one NCAS link is allowed for QSIP Application. When the link is active for QSIP application, subsequent QSIP application request to create another NCAS link will be ignored.

- QSIP application has lowest priority. Therefore, in case of high traffic and/or abnormal conditions, QSIP application will not response with the data within the timeout period.
- The T1 timer for the query and response is controlled by the office engineering parameter, Table OFCENG, AIN_T1_TIMER in the core.
- During failover cases, the NCAS link is disconnected with the core and re-established from the active side. All outstanding QSIP request prior to failover complete will be discarded and no response will be provided.

49.6 Interactions

The QSIP command from the core is a stand alone command. In the core, the QSIP CI increment send a request to CS2K SS platform. The software developed under this activity gathers the static and dynamic data associated with the specific SIP line, and sends an asynchronious response to QSIP CI in the core.

The QSIP request, data collection and sending response are independent from other activities/actions/events in the CS2K SS platform. Therefore, no specific interaction anticipated by this activity.

49.7 Glossary

Term	Description
CI	Command Interface
CS2K	Communication Server 2000
GUI	Graphical User Interface
NCAS	Non-Call Associated Signalling
OAM	Operation, Administration and Maintenance
QSIP	Query SIP Line data
SCP	Switching control point
SCPLite	SCP like functionality
SCTP	Steam Control Transport Protocol
SIP	Session Initiation Protocol
SS	Session Server

50: Functional description (FN): A00009252

50.1 Feature name

A00009252 Multi-Time Zone AMA Enhancments

50.2 Description

In order to support networks that span Multiple Time Zones (MTZ) features in the Succession/CS2K products must be enhanced. Feature A59038784 introduced a framework to support MTZ and DST (Daylight Savings Times) for subscriber visible services. Feature A00009120 (done in parallel with this feature) extends this framework.

This feature allows the customer to record a corrected timestamp for billing records that originate on agents with the MTZ line option. The connect timestamp will be modified to the agents time zone and this timestamps will be appended to the existing billing record in AMA using a module code and SMDR using an extension record.

Table AMAOPTS contains a new switch wide option (RECORD_MTZ) that will allow customers to use the MTZ option and decide whether or not they want to record the modified timestamp.

50.3 Software Requirements or Dependencies

SN09

50.4 Limitations and restrictions

The limitations and restrictions specified in activity A59038784 and A0009120 are also applicable to this activity.

In addition the following limitations and restrictions apply:

- This feature will not FORCE billing records, it will only append the information if a billing record exists.
- This Feature only modifies the Connect time stamp.
- Billable calls that terminate to an agent with the MTZ option will not generate a modified timestamp.

50.5 AMA

The addition of the MTZ line option and corresponding MULTITM datafill will append module code 611 (context ID 80200) that contains a modified connect time and date. The record will look as follows:

50.6 SMDR

50.7 Interactions

This feature interacts with the Multi-Time Zone feature, A59038784 and A0009120 Multi-Time Zone Enhancments.

50.8 Glossary

Term	Description
MTZ	Multi-Time Zone Enhancment
AMA	Automatic Message Accounting
SMDR	Station Message Detailed Recording

51: Functional description (FN): A00009280

51.1 Feature name and Feature ID

A00009280: MG9K Line Circuit Enhancements

51.2 Description

The MG9K EM Line Circuit Enhancements concentrates on the below requirements for SN09 release:

1> Color indication for alarms on the port ilog of the Card Display.

2> User can manually mark a port as faulty.

3> Color indication for faulty port on the port ilog of the Card Display.

4> Display of directory number in the LineCircuit view

5> Display of directory number at the Alarm Browser screen for alarms reported.

Also the associated directory number would get added in the line circuit alarm log.

6> Circuit Listing at the NE desktop level to list the faulty ports.

51.3 Alarms display at the Port level

The line circuit ilogs on a LineCard would be displayed with an appropriate alarm color (if any alarm exists on the line circuit). User can easily make out the ports with alarms without opening a Port View. Currently alarms show in color at many different levels in the EM such as the shelf and card but not at the port level. After the addition of this functionality EM would be consistent at all levels in displaying alarms. The existing port view would not be changed. WLC,XDSL,GLC and SAA card view currently displays a list of line circuits. Existing alarm colors would be used to indicate the appropriate alarms on the port ilog of a line card view.

say: Critical alarm: Red
Major alarm: Red
Minor alarm: Orange
Warning : Yellow

51.3.1 Manually marking a port as faulty from the Port view

The new Line Circuit view would enable a User to mark a port (line circuit) as faulty. User can mark a port as faulty only when it is locked. Authorization level for this method would be ‘ewsmtc’. Fault setting option would be disabled (greyed out) if the port is unlocked.

User would get a warning message when he tries to unlock a faulty port. But if User wishes to go ahead irrespective of the port being marked as faulty, the request would get submitted.

'Fault State' field would be added in the 'Circuit Status' section of a port view. This new variable will be persisted only on the EM. There is no associated MIB variable for this state.

51.3.2 Display of faulty ports with a specific color

Currently User has no indication of the port being faulty. This functionality would help User to indentify a faulty port/circuit from the Line Card View.

A faulty port would be displayed with magenta color. Faulty color indication on a port would take precendence over alarms color indication.
say: A port which has alarms and is also marked by the User as faulty would be displayed with magenta color.

51.4 Display of Directory number(DN) at the Line Circuit view

With every line circuit associated to a VMG, there can be an associated DN. The DN will be displayed in the 'Circuit Provisioning' section of the Line Circuit view.

This would help the User to be positive that he is on the correct port. Display of the directory number that is associated with a port ensures proper location.

If the DN is not yet created for a line circuit, then the field would have 'None' as the value.

Any subsequent changes to DN would get udpated on a open Line Circuit view.

51.5 Display of Directory number(DN) on Alarm Browser

Directory number(DN) associated with a particular Line Circuit would be displayed in the description part of the Line Circuit alarm on a Alarm Browser.

eg: The description part of a line circuit alarm would have an added entry
`DN Affected: 6195210102`
If no DN is associated with the line circuit, then the description part of the line circuit alarm would have an appended entry saying
`DN Affected: None`
DN associated when the alarm was reported would be displayed. Any subsequent changes to the DN would not get updated on the Alarm Browser.

Physical location and the directory number details for a line circuit alarms would be helpful in troubleshooting.

Alarm log would also reflect the DN associated with the line circuit alarm.

51.6 'Faulty Circuit Listing' view at the NE Desktop level

A new menu item would be added in Services Menu list, on NE desktop view, namely 'Faulty Circuit Listing'. Clicking this menu item would display the 'Faulty Circuit Listing' view which has the below

information:
1> Associated Frame number
2> Associated Shelf number
3> Associated Slot number
4> Port Number

'Faulty Circuit Listing' view at NE desktop level would have readonly values. This GUI would have an associated time stamp and a refresh button. Refresh button is used to refresh the GUI with the latest port being marked as faulty. Refresh button is used to avoid dynamic updates when the faulty status of the port changes.
Timestamp would reflect the last time when the 'Refresh' button was used to collect the latest faulty ports information.

51.7 Hardware Requirements or Dependencies

None

51.8 Software Requirements or Dependencies

None.

51.9 Limitations and restrictions

- User will be allowed to mark a port/line circuit as faulty only when it is locked.
- User would get an appropriate warning message when he tries to do unlock a faulty port.
- XDSL Data Circuits cannot be marked as faulty.
- Fault color display on a line circuit would take precedence over alarm color indication.
- No new color indication would be displayed for a port which is locked.
- Once the line circuit alarm is reported to the Alarm Browser, any subsequent changes to the DN of that particular Line Circuit would not get updated in the description part of the Alarm Browser for a line circuit alarm.
- Existing Circuit Listing GUI would not be changed. Line Card level circuit listing GUI will behave as before and would not undergo any changes as a part of this feature

51.10 Interactions

None.

51.11 Glossary

Term	Description
WLC	World Line Card
SAA	Service Adaptive Access
XDSL	X Digital Subscriber Line Card

Term	Description
MG9k	Media Gateway 9000
MG9K-EM	Media Gateway 9000 - Element Manager
GLC	Global Line Card
DN	Directory Number

52: Functional description (FN): A00009282

52.1 Feature name and Feature ID

A00009282: Emergency Stand Alone (ESA) Multiple Level Precedence and Preemption (MLPP) for MG9KEM

52.2 Description

MLPP is a Defense Switched Network (DSN) feature provided today in the Legacy environment. This feature provides MLPP off the MG9K for deployment of Succession to the United States Government. The MLPP feature provides a user with the ability to preempt a call in progress. If the originator dials a precedence level that is higher than the call which the terminator is involved, the call may be preempted. This feature is typically used in emergency situations and not during normal day to day phone calls.

MLPP in ESA will be supported on all platforms (ATM, IP, GigE) but only for Enhanced ESA. Enhanced ESA is required for the MG9K to receive the line and translation data necessary to support precedence dialing and preemption. As such, MLPP will interwork with the supported Enhanced ESA line services feature set across all nodes. This includes InterNodal ESA, AUL, Hunt Groups, and MADN.

Two attributes are provisioned for each Termination- if the line is preemptable, and its precedence.

The Element Manager receives this data from the Core in the form of an XML document, transferred using secure mechanisms. This data is not modified by the Element Manager, but is converted into a form for the MG9000. No editing of this data is done by the MG9000. However, these values are displayed at the appropriate views.

52.3 Hardware Requirements or Dependencies

None

52.4 Software Requirements or Dependencies

This ESA activity on the MG9K is dependent upon two additional activities for successful completion and will be integrated together under an ICAF:

Core -ESA MLPP (A00009119)

MLPP ESA on MG9K (A00009497)

ESA MLPP - ICAF (A00009423)

52.5 Limitations and restrictions

- The ESA data from the core will be autonomously downloaded to the MG9000 only once every 24 hours.
- ESA data can be manually downloaded from the core and sent to individual VMGs.
- MLPP is activated on the MG9K by the presence of precedence dialing for a termination. This can only be activated from a DSN switch provisioning precedence and preemption information per line on the MG9K.
- The MG9000 EM will not allow the modification of any ESA data retrieved from the core.
- Data and views relating to MLPP data will not be visible in non-MLPP offices.

52.6 Interactions

None

52.7 Glossary

VMG	Virtual Media Gateway

53: Functional description (FN): A00009289

53.1 Feature name and Feature ID

A00009289 - IEMS (Integrated Element Management System) - 10 Minute Default on User Inactivity Timer

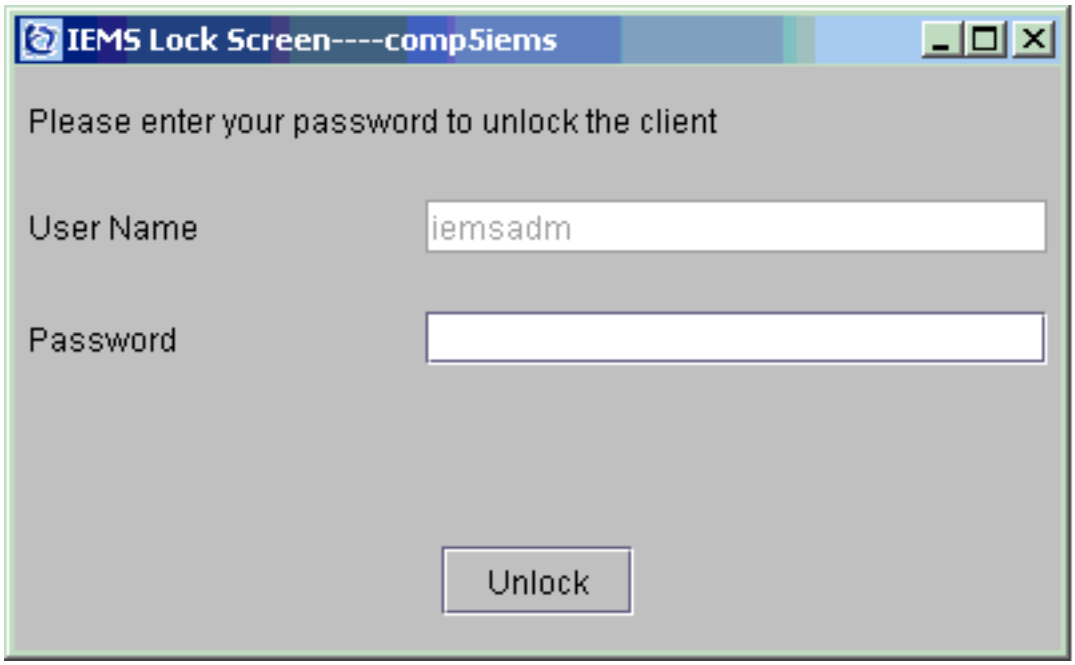
53.2 Description

In SN07, IEMS introduced a client inactivity timer that locked the client after a configurable period of time. Inactivity is defined as a lack of mouse actions - whether it be clicks or movements - on the IEMS screen. The inactivity timer functionality then locked the client until the user correctly entered his or her password. This basic security mechanism did not fully meet the customer requirements for security, so this feature further refines the existing IEMS client timeout to further meet those requirements.

With this feature, in addition to the existing locking of the IEMS client, the lockout timer will include the following:

- ability to change timeout value without requiring a restart of the server
- successive failed attempt lockout functionality to prevent multiple, rapid attempts to guess a password and unlock the client
- ability for the user to disable the client lockout will be removed

The new lock screen will look similar to the previous lock screen, without the option to disable it.



For more information on how to configure the timeout values, see the FN for A00008858 (http://ptm -> Documentation -> SN09).

When the user fails in 3 successive login attempts, they will be presented with a dialog box informing them that they will be unable to attempt to relogin again for a configured amount of time and the unlock button on the above window will be disabled. (Screen capture to be provided prior to IT declaration.)

The other additional functionality added this release is session termination after a specified inactivity timeout. The user will first see the GUI lock and then, if no action is taken before the user termination timer expires, the session will be terminated. This is consistent with other SSPFS based applications such as CMT and MG9KEM.

53.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies.

53.4 Software Requirements or Dependencies

This will require an SN09 or later version of SSPFS.

53.5 Limitations and restrictions

The IEMS HTML client will not timeout in this release. It will be supported in future IEMS releases.

53.6 Interactions

N/A.

53.7 Glossary

Term	Description
IEMS	Integrated Element Management System

54: Functional description (FN): A00009292

54.1 Feature name and Feature ID

IEMS: UserID-based Partitioning by NE, A00009292.

54.2 Configuring rules using the Custom View Scope

Using the Custom View Scope, rules can be set such that the view can be customized as per the customer's requirement. Rules can be set at various levels which allow filtering at different levels.

The partitioning rules that can be set on user groups such that a user belonging to a particular user group has a set of predefined access as governed by the rules. Note that Custom View Scopes cannot be added to the standard Carrier Voice over IP user groups.

The IEMS has 5 modules under which rules can be set. They are

1. Topology
2. Events
3. Alerts
4. Inventory
5. Stats Admin

Among these modules, Topology and Inventory modules are almost similar and rules set on any one of them is reflected to the user.

- Configuring Rules using the Topology / Inventory module
- Configuring Rules using the Event module
- Configuring Rules using the Alert module
- Configuring Rules using the Stats Admin module

Note: The terminology used for Maps is "**Topology**" and for Network Database is "**Inventory**".

54.3 Configuring Rules using the Topology / Inventory module

Integrated EMS administrator can add the authorized custom view scope to non-Carrier Voice over IP group using the Topology / Inventory module. This section describes Integrated EMS Security and Administration procedure to add the authorized custom view scope to a group using the Topology / Inventory module

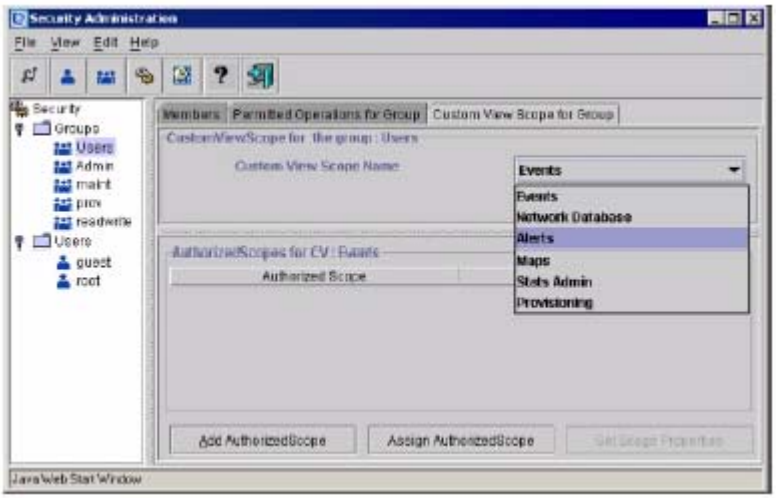
To add an authorized custom view scope to the group using the Topology/ Inventory module, follow these steps:

In the Security Administration tool of Integrated EMS

1 Launch the Security Administration tool (refer to the "Starting the Security Administration tool").

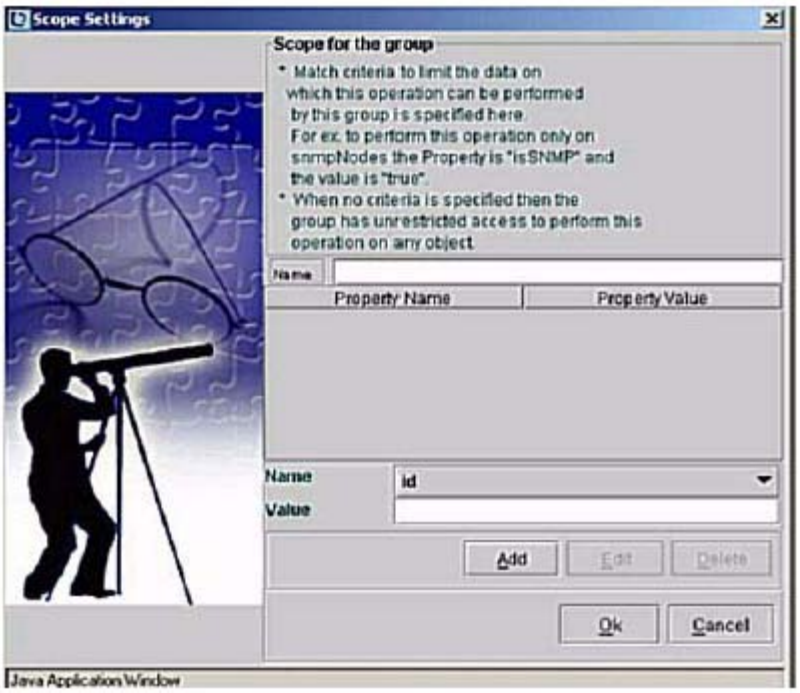
2 Select the required group under the Groups node in the Security tree.

3 Click the **Custom View Scope for Group** tab in the right-hand panel. The "Custom View Scope for the groups" window opens, as shown in the following figure.



4 Select the Topology / Inventory custom view scope name from the drop-down menu.

5 Click the **Add AuthorizedScope** button. The Scope Settings dialog opens, as shown in the following figure.



6 Specify a name for the created custom view in the **Name** text field. Then select a “Property Name” from *Name* drop-down box. This drop-down box lists the property names (which can be used for creating the authorized scopes) specific to each of the custom view scopes. The property names and the values for Topology/Inventory currently used in Integrated EMS are listed in the table below. List of all property names that can be use for partitioning, see Properties used in IEMS for CVS

Property Name	Property Value
DisplayName	Name assigned to the device added to IEMS Example (GWC*, CO*, MG*, etc)
Ipaddress	IP address of the devices added to IEMS Example (47.142.106.220, 47.142.*.* for particular subnet etc)
EmIpaddress	IP address of the Element Manager added to IEMS Example (47.142.122.200, 47.142.*.* for particular subnet etc)
Managed	True, False

Status	1(i.e., Critical), 2(i.e., Major), 3(i.e., Minor), 4(i.e., Warning), 5(i.e., Clear), 6(i.e., Info), 7(i.e., Unknown)
DeviceVersion	Version of the devices added to IEMS Example (7.0, 8.0, 9.0)

7 Click the **Add** button to add the Authorized Scope for the selected Custom View Scope of the group.

8 Click the **OK** button to update the scope details in the Integrated EMS Server.

Note: To identify more than one property value, separate each value using the appropriate operators (refer to the "Setting custom view scope properties"). Example: !GWC* -> This will show all the NEs except starting name with GWC

Note: The multiple criteria can be form by using the composite CVS rule. Example: Partitioning based on the set of Display Names and belonging to one subnet, this can be achieved by setting two rules in same module.

displayName as GWC*

IPaddress as 47.1.*.*

54.4 Configuring Rules using the Event module

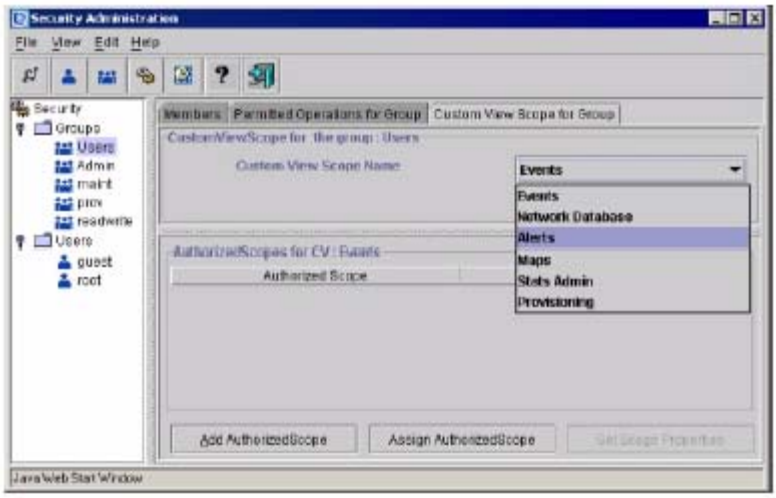
Integrated EMS administrator can add the authorized custom view scope to non-Carrier Voice over IP group using the Event. This section describes Integrated EMS Security and Administration procedure to add the authorized custom view scope to a group using the Event module

To add an authorized custom view scope to the group using the Event, follow these steps:

In the Security Administration tool of Integrated EMS

1. Launch the Security Administration tool (refer to the “Starting the Security Administration tool”).
2. Select the required group under the Groups node in the Security tree.
3. Click the **Custom View Scope for Group** tab in the right-hand panel.

The “Custom View Scope for the groups” window opens, as shown in the following figure.



4. Select the Event custom view scope name from the drop-down menu.
5. Click the **Add AuthorizedScope** button. The Scope Settings dialog opens, as shown in the following figure.

6. Specify a name for the created custom view in the **Name** text field. Then select a “Property Name” from *Name* drop-down box. This drop-down box lists the property names (which can be used for creating the authorized scopes) specific to each of the custom view scopes. The property names currently used in Integrated EMS and the values it can take are listed in the table below. List of all property names that can be use for partitioning, see Properties used in IEMS for CVS

Property Name	Property Value
Category	Category of Events Example (communication, processingError, qualityOfService, equipment, others etc)
LogName	Generated log name Example (IEMS, EMJS, PP etc)
LogNumber	Generated log number Example (398, 640, 641 etc)
LogKey	Combination of both LogName and LogNumber Example (IEMS398, EMJS640, PP318 etc)
EventType	Type of event Example (TBL, INFO, FLT etc)
ComponentId	Example (SAM21, STORM etc)
ProbableCause	Cause of event Example (communicationSubsystemFailure, underlyingResourceUnavailable etc)
EquipmentIdentifier	Identifier of devices added to IEMS Example (IpAddress of NE/EM etc)
EventLabel	Label on Event Example (Alarm set, IEMS OM collection job alarm etc)
Severity	1(i.e., Critical), 2(i.e., Major), 3(i.e., Minor), 4(i.e., Warning), 5(i.e., Clear), 6(i.e., Info), 7(i.e., Unknown)

7. Click the **Add** button to add the Authorized Scope for the selected Custom View Scope of the group.
8. Click the **OK** button to update the scope details in the Integrated EMS Server.

Note: To identify more than one property value, separate each value using the appropriate operators (refer to the "Setting custom view scope properties"). Example: IEMS* -> This will show all the Events starting with IEMS as a LogKey property .

54.5 Configuring Rules using the Alert module

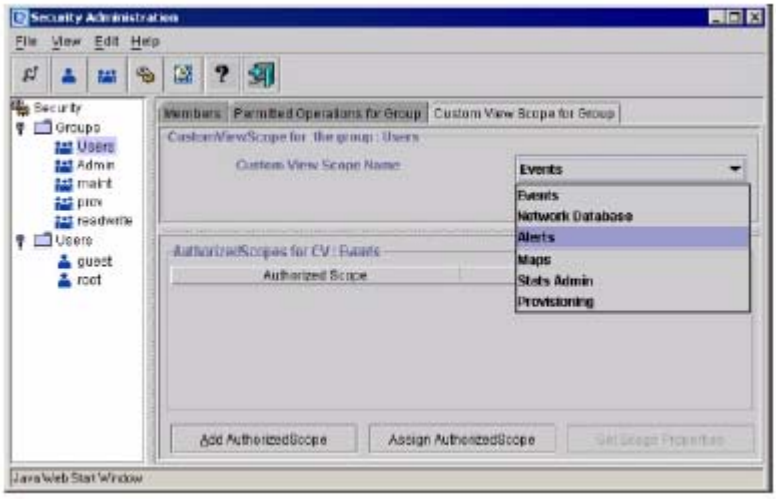
Integrated EMS administrator can add the authorized custom view scope to non-Carrier Voice over IP group using the Alert. This section describes Integrated EMS Security and Administration procedure to add the authorized custom view scope to a group using the Alert module

To add an authorized custom view scope to the group using the Alert, follow these steps:

In the Security Administration tool of Integrated EMS

1. Launch the Security Administration tool (refer to the "Starting the Security Administration tool").
2. Select the required group under the Groups node in the Security tree.
3. Click the **Custom View Scope for Group** tab in the right-hand panel.

The "Custom View Scope for the groups" window opens, as shown in the following figure.



4. Select the Alert custom view scope name from the drop-down menu.
5. Click the **Add AuthorizedScope** button. The Scope Settings dialog opens, as shown in the following figure.

6. Specify a name for the created custom view in the **Name** text field. Then select a “Property Name” from *Name* drop-down box. This drop-down box lists the property names (which can be used for creating the authorized scopes) specific to each of the custom view scopes. The property names currently used in Integrated EMS and the values it can take are listed in the table below. List of all property names that can be use for partitioning, see Properties used in IEMS for CVS

Property Name	Property Value
Category	Category of Events Example (communication, processingError, others etc)
EquipmentIdentifier	Identifier of devices added to IEMS Example (IpAddress of NE/EM, Display name of NE/EM etc)
LogKey	Combination of both LogName and LogNumber Example (IEMS398, EMJS640, PP318 etc)
ProbableCause	Cause of event Example (communicationSubsystemFailure, underlyingResourceUnavailable etc)
Severity	1(i.e., Critical), 2(i.e., Major), 3(i.e., Minor), 4(i.e., Warning), 6(i.e., Info), 7(i.e., Unknown)

7. Click the **Add** button to add the Authorized Scope for the selected Custom View Scope of the group.
8. Click the **OK** button to update the scope details in the Integrated EMS Server.

Note: To identify more than one property value, separate each value using the appropriate operators (refer to the "Setting custom view scope properties"). Example: IEMS* -> This will show all the Alerts starting with IEMS as a LogKey property

54.6 Configuring Rules using the Stats Admin module

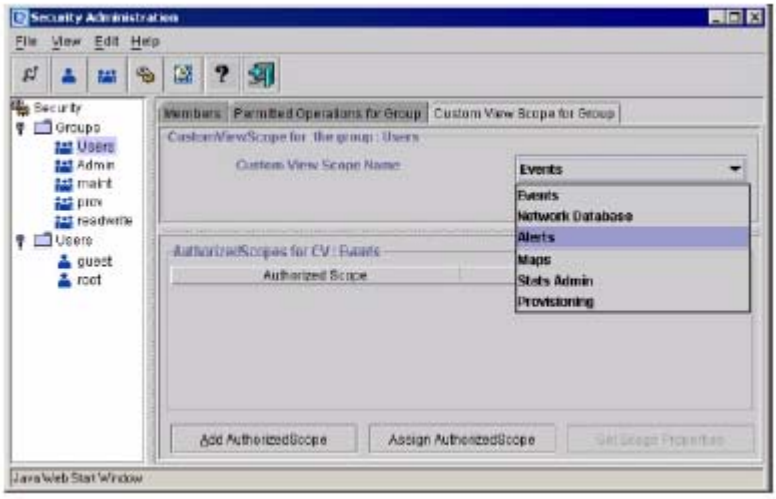
Integrated EMS administrator can add the authorized custom view scope to non-Carrier Voice over IP group using the Stats Admin. This section describes Integrated EMS Security and Administration procedure to add the authorized custom view scope to a group using the Stats Admin module. Stats Admin module is basically for partitioning the Performance Collection Data using supported properties.

To add an authorized custom view scope to the group using the Stats Admin, follow these steps:

In the Security Administration tool of Integrated EMS

1. Launch the Security Administration tool (refer to the “Starting the Security Administration tool”).
2. Select the required group under the Groups node in the Security tree.
3. Click the **Custom View Scope for Group** tab in the right-hand panel.

The “Custom View Scope for the groups” window opens, as shown in the following figure.



4. Select the Stats Admin custom view scope name from the drop-down menu.
5. Click the **Add AuthorizedScope** button. The Scope Settings dialog opens, as shown in the following figure.

6. Specify a name for the created custom view in the **Name** text field. Then select a “Property Name” from *Name* drop-down box. This drop-down box lists the property names (which can be used for creating the authorized scopes) specific to each of the custom view scopes. The property names currently used in Integrated EMS and the values it can take are listed in the table below. List of all property names that can be use for partitioning, see Properties used in IEMS for CVS

Property Name	Property Value
Name	Name of Job Example (CollectionJob*)
Agent	Name of component for which Collection is enable Example (GWC*)
DNSName	Name of DNS used (can use IP address also) Example (47.166.56.10)

ID	Poll ID Example (1, 2, 100 or 243 etc)
Protocol	Used Protocol Example (SNMP etc)
NumericType	1 for numbers and 2 for string
OID	Identifier for Object that is Data Identifier Example (.1.3.6.1.2.1.1.1.0)
Threshold	The value is set to true if the threshold value is set for the collection data and false if threshold value is not set
IsMultiplePolledData	True, False

7. Click the **Add** button to add the Authorized Scope for the selected Custom View Scope of the group.
8. Click the **OK** button to update the scope details in the Integrated EMS Server.

Note: To identify more than one property value, separate each value using the appropriate operators (refer to the "Setting custom view scope properties"). Example: !GWC* -> This will show all the Agent's Collection except starting name with GWC

54.6.1 Properties used in IEMS for CVS

All the property names currently used in Integrated EMS and the respective modules are listed in the table below.

Modules	Property Name
Topology	name, displayName, managed, status, isContainer, ipAddress, primaryIpAddress, secondaryIpAddress, timeZone, deviceVersion, FIState, SystemUnmanageState, platformAddress
Events	id, text, category, severity, time, source, node, logName, logNumber, logKey, sequenceNumber, eventType, componentId, probableCause, specificProblem, equipmentIdentifier

Alerts	entity, id, message, category, severity, modTime, createTime, who, source, logName, logKey, sequenceNumber, eventLabel, eventType, componentId, probableCause, specificProblem, equipmentIdentifier
Inventory	name, displayName, managed, status, isContainer, ipAddress, primaryIpAddress, secondaryIpAddress, timeZone, deviceVersion, FIState, SystemUnmanageState, platformAddress
Stats Admin	name, id, agent, oid, threshold, isMultiplePolledData, numericType, previouslySeverity, statsDataTableName, protocol, dnsName, lastTimeValue

55: Functional description (FN): A00009294

55.1 Feature name and Feature ID

T.38 Annex D interworking with SIP. It is covered activity ID A00009294.

55.2 Description

55.2.1 Overview

ITU-T Recommendation T.38 [T.38] describes the technical features necessary to transfer facsimile documents in real-time between two standard Group 3 facsimile terminals over the Internet or other networks using IP protocols. The Recommendation allows the use of either TCP or UDP depending on the service environment.

The annex D/T.38 describes system level requirements and procedures for Internet-aware facsimile implementations and Internet-aware facsimile gateways conforming to ITU-T Rec. T.38 to establish calls with other ITU-T T.38 implementations using the procedures defined in RFC 2543 (SIP) and RFC 2327 (SDP).

This activity intends to provide T.38 Annex D interworking support for SIP with a PVG on H.248.

This feature provides “Call Server controlled switch over to T.38” depending on T.38 network option:

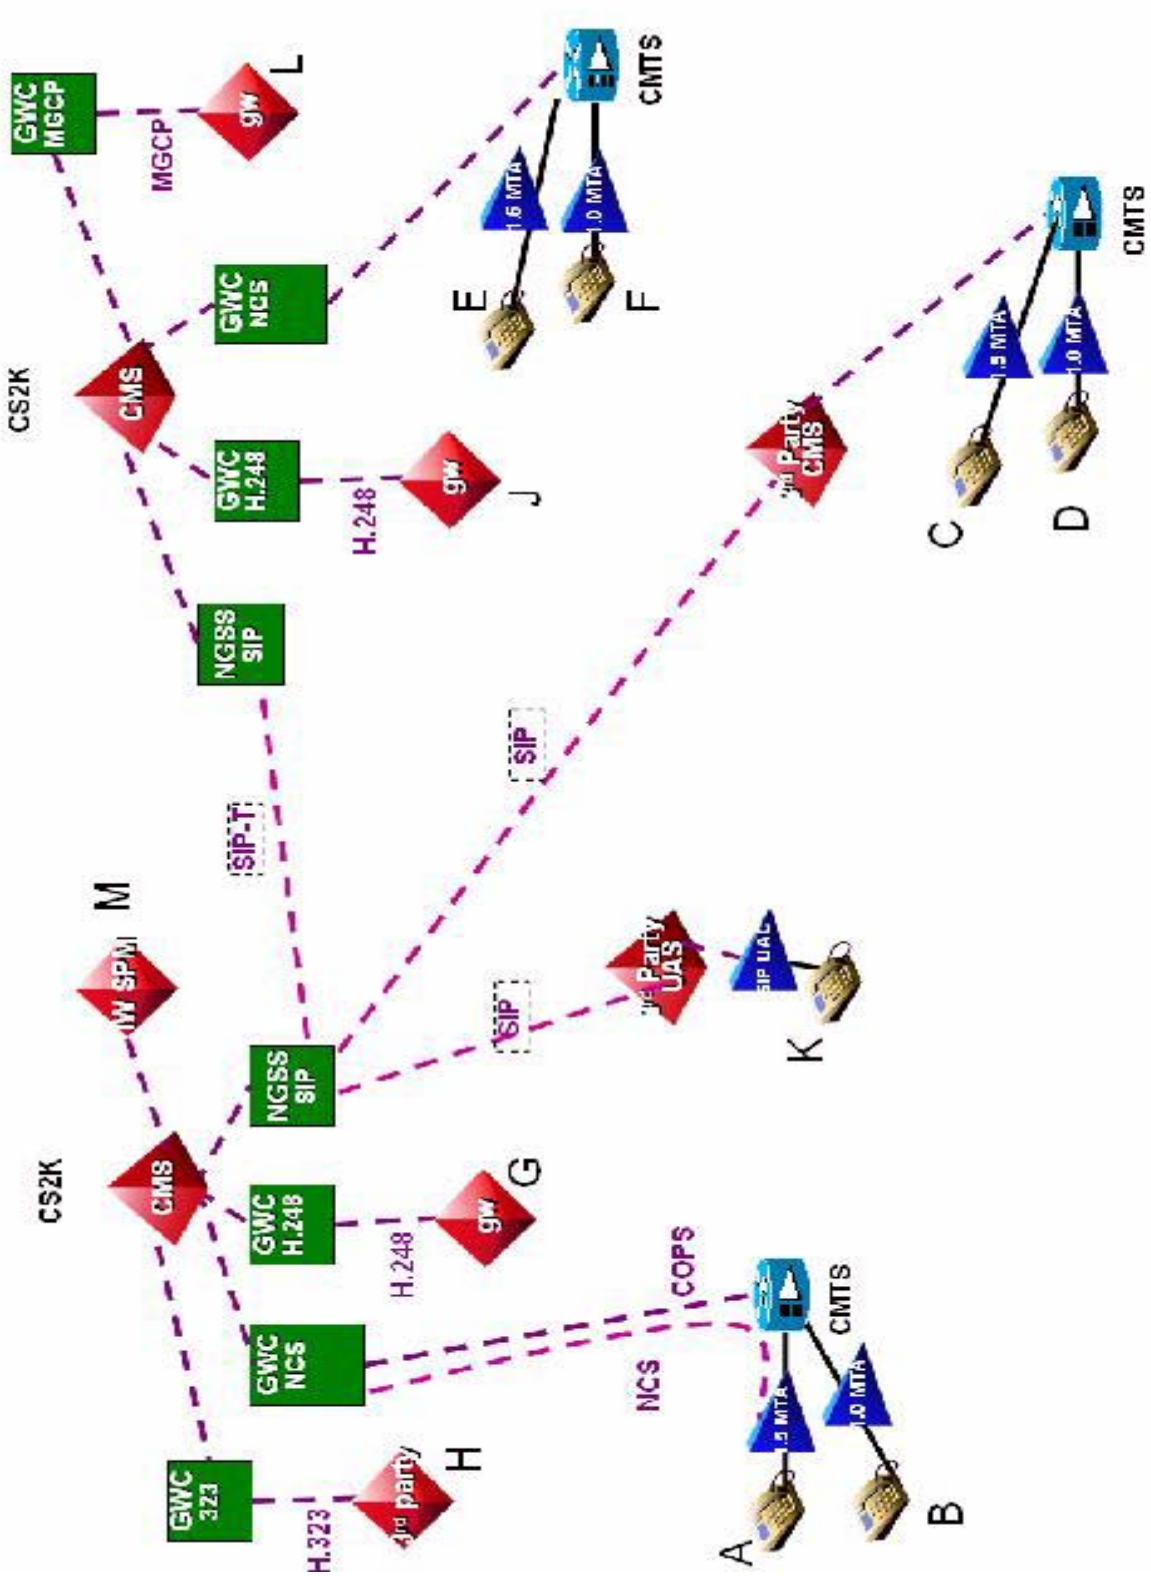
If in the Gateway controller configuration, **T.38 is enabled in the network codec profile provisioning** and H.248 GW supports T.38, then upon fax detection, switch over is done from G.729 (or G.711) to T.38 codec.

And if in the Gateway controller configuration, **T.38 is disabled in the network codec profile provisioning**, or the H.248 GW does not support T.38, then switch over to T.38 does not apply.

This activity is in parallel to the SN09 activity A00009443 which includes development on the DPT/GWC.

This feature does not impact the capability of a GW to do autonomous switch over to T.38.

55.2.2 Overall T.38 interop scenario



In SN07, T.38 is supported as follows:

- H.323 to/from H.248 PVG (G-H, G-J scenarios)
- PVG to/from MGCP IAD (G-L)
- PVG to/from IW SPM (J-M)
- IW SPM to/from MGCP IAD (M-L)
- AudioCodes M2K to/from IW SPM/MGCP IAD/ PVG

With this activity we are supporting a T.38 Interworking with 3rd Party SIP servers.

This is the G-K or J-K (CS2Ks in TANDEM) scenarios referring to the diagram above.

55.2.3 Communication between gateways

55.2.3.1 Call setup

Call setup for Annex D/T.38 compliant implementations is based on SIP (Session Initiation Protocol) defined in RFC 2543. The implementations may operate in two distinct compatible environments:

55.2.3.1.1 A facsimile-only over IP environment

The emitting gateway sends a SIP INVITE request (with the appropriate options set) for a T.38 facsimile connection with the receiving SIP server. The receiving server will likely be the receiving gateway; however, it may also proxy or redirect the SIP connection to the actual gateway through SIP or other means. In any case, a response will be sent to the emitting gateway indicating acceptance, redirection or failure of the request.

If accepted (or a redirected INVITE is accepted), the T.38 facsimile call proceeds. Once the call is completed, the call may be disconnected with a SIP BYE command.

55.2.3.1.2 A facsimile and voice over IP environment

A SIP INVITE is made to the called party requesting a voice connection per the requirements of RFC 2543. A voice connection is then established.

Upon detection of facsimile by the receiving gateway, a SIP INVITE request is sent to the emitting gateway (with the same Call-ID as the existing voice connection) for a T.38 facsimile connection. Upon completion of the facsimile

call establishment (noted in D.2.2.3), the T.38 facsimile call proceeds with a T.38 V.21 flags indicator packet.

Note that during this switch over and the facsimile call, it may be useful to mute the voice channel. The voice channel may be used again once the end of facsimile transmission is detected. Alternately, some implementations may choose to replace the voice channel with a facsimile channel.

This activity implements the facsimile and voice over IP environment where the voice call is first set-up and then a switch over to T.38 is triggered.

55.2.3.2 Basic call setup

Implementation of “Call Server controlled switch over to T.38 mode”, makes use of “Call Type Discriminator package” (ctyp) with event “Discriminating Tone detected” (dtone).

The GWC checks the GW capability to support T.38 via H.248 AuditValue command. If in the responded list of the packages of the H.248 GW, “ctyp-1” is present, then “Call Server controlled switch over to T.38 mode” is supported - see Figure 1, on page 452 .

If T.38 is enabled in the Network codec profile provisioning in Network Configuration, the H.248 GWC add the ephemeral termination with voice and T.38 codec - see Figure 4, on page 453 .

The H.248 SDP samples below display H.248 message as used in the call flow examples. See “Example Call Flows” on page 455.

	}}}}}

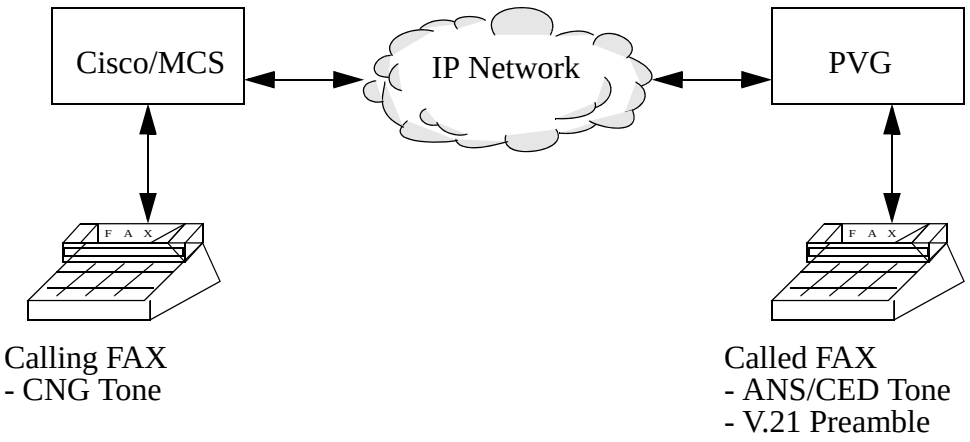
55.2.4 This activity accommodates two scenarios:

Assuming that there are no NACKs from either side of the connection, there are two possible scenarios: when the call is initiated form either end.

55.2.4.1 T.38 fax calls originating from SIP/NGSS and terminating at PVG.

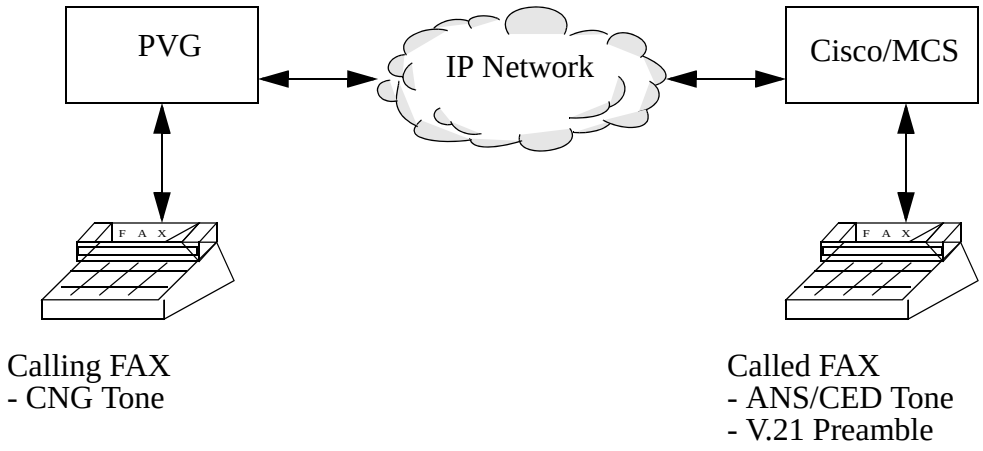
Figure 5



- A SIP Invite is sent to the CS2K by the CISCO/MCS requesting a voice connection.
- A voice connection is then established.
- Upon detection of fax tone by the receiving gateway i.e. the PVG, it sends a V.21notification to CS2K.
- CS2K then sends a SIP Re-Invite request to the emitting gateway (with the same Call-ID as the already existing voice connection) for a T.38 facsimile connection.
- Upon completion of the facsimile call establishment, the T.38 fax call proceeds with a T.38 V.21 flags indicator packet.

55.2.4.2 T.38 fax calls originating from PVG and terminating at SIP/ NGSS.

Figure 6



- For calls originating from the PVG end, a SIP Invite is sent to the CISCO/ MCS requesting for a voice connection.
- Then a voice connection is established.
- A V.21 notification is received by the CISCO/MCS.
- It sends a re-invite to the originating side (which is the PVG here). Then the switch-over to T.38 occurs.

55.2.5 Example Call Flows

Description of T.38 Annex D functionality is provided via call flows. The description of the first call flow is given in detail and may be applied to other subsequent call flows.

55.2.5.1 Basic Call Scenario: SIP to PVG interworking.

When the call is originated from the CISCO/MTS SIP endpoint:

Note 1: After receiving an INVITE from the SIP endpoint, a voice call is established. If in the Gateway controller configuration, T.38 is enabled in the network codec profile provisioning the ephemeral is added, and the PVG is asked to choose from m = audio $$$ m = image $$$..

Note 2: H248 GWC requests for all events on the ctyp/dtone package.

Note 3: The PVG replies with the intersection of the PVG capability and the offer from SIP, which is sent to the remote SIP end point. At this point voice call is established.

Note 4: The PVG then reports any detected ctyp/dtone event to the GWC.

Note 5: Upon detection of a CNG or a V.21 flag the GWC will send a modify to the PVG with the local descriptor m=image $ udptl t38.

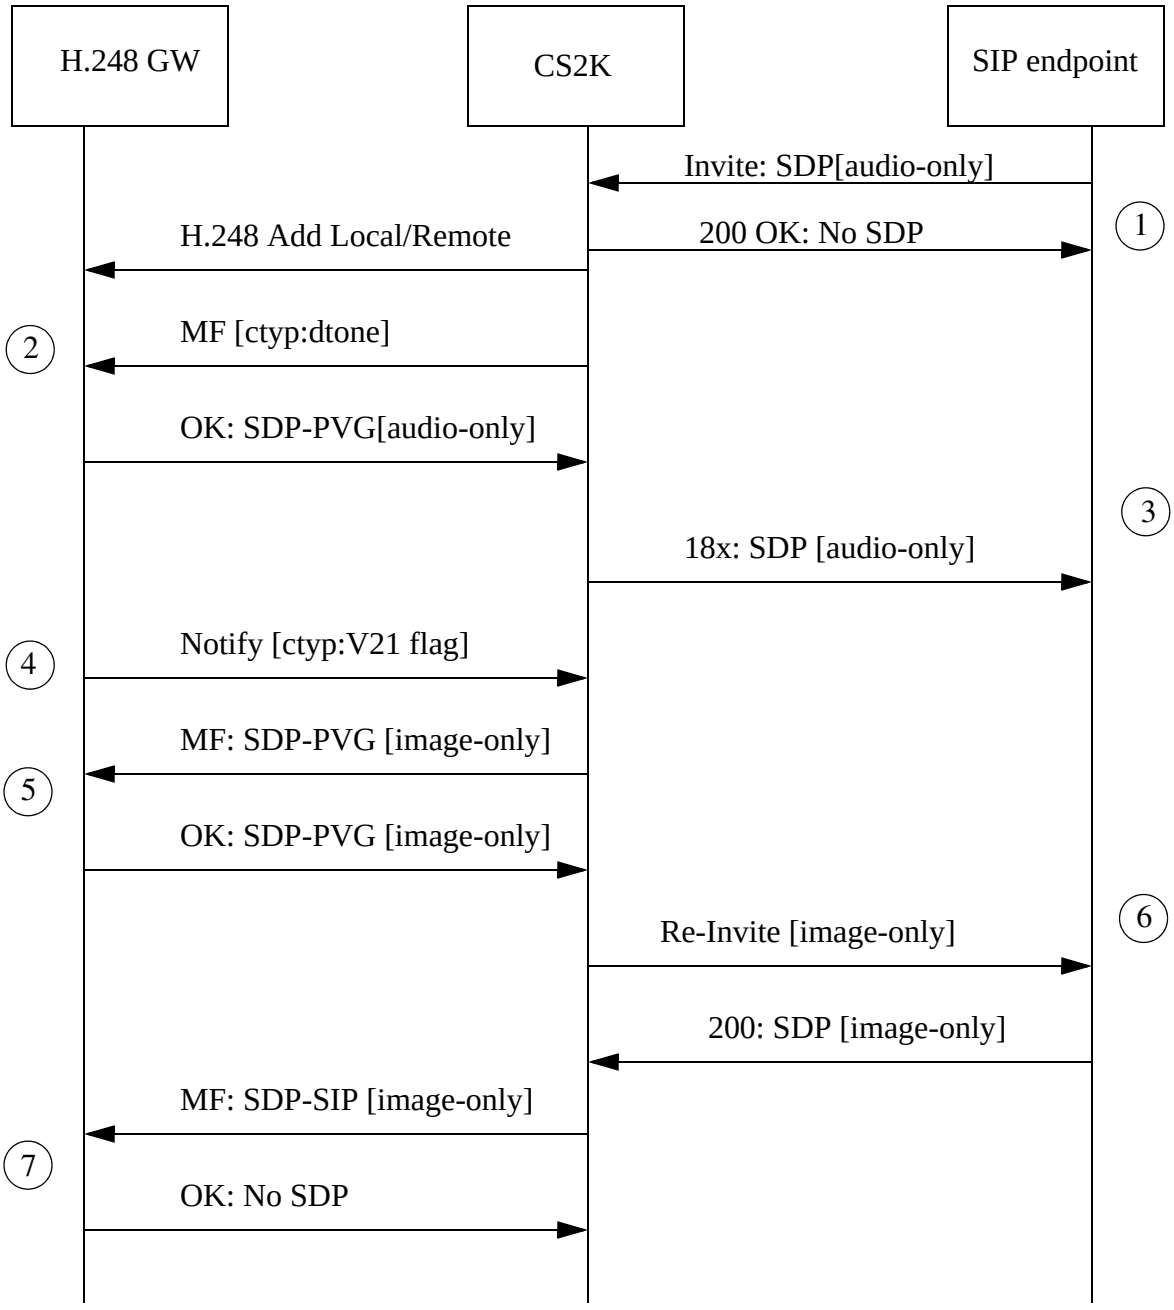
Note 6: CS2K sends image only SDP to the remote SIP end point in Re-INVITE message.

Note 7: Upon receipt of SDP(T.38) from remote SIP end point, CS2K sends an usual modify. At this point a fax call using T.38 is established.

Note 8: The content of SDP uses following abbreviation:

- SDP(audio) for processing of audio media stream.
- SDP(t38) for processing of t38 media stream.
- SDP(audio, t38) for simultaneous processing of audio and t38 media streams.
- SDP(audio, t38-cap) for processing of audio media stream and for t38 capability indication.

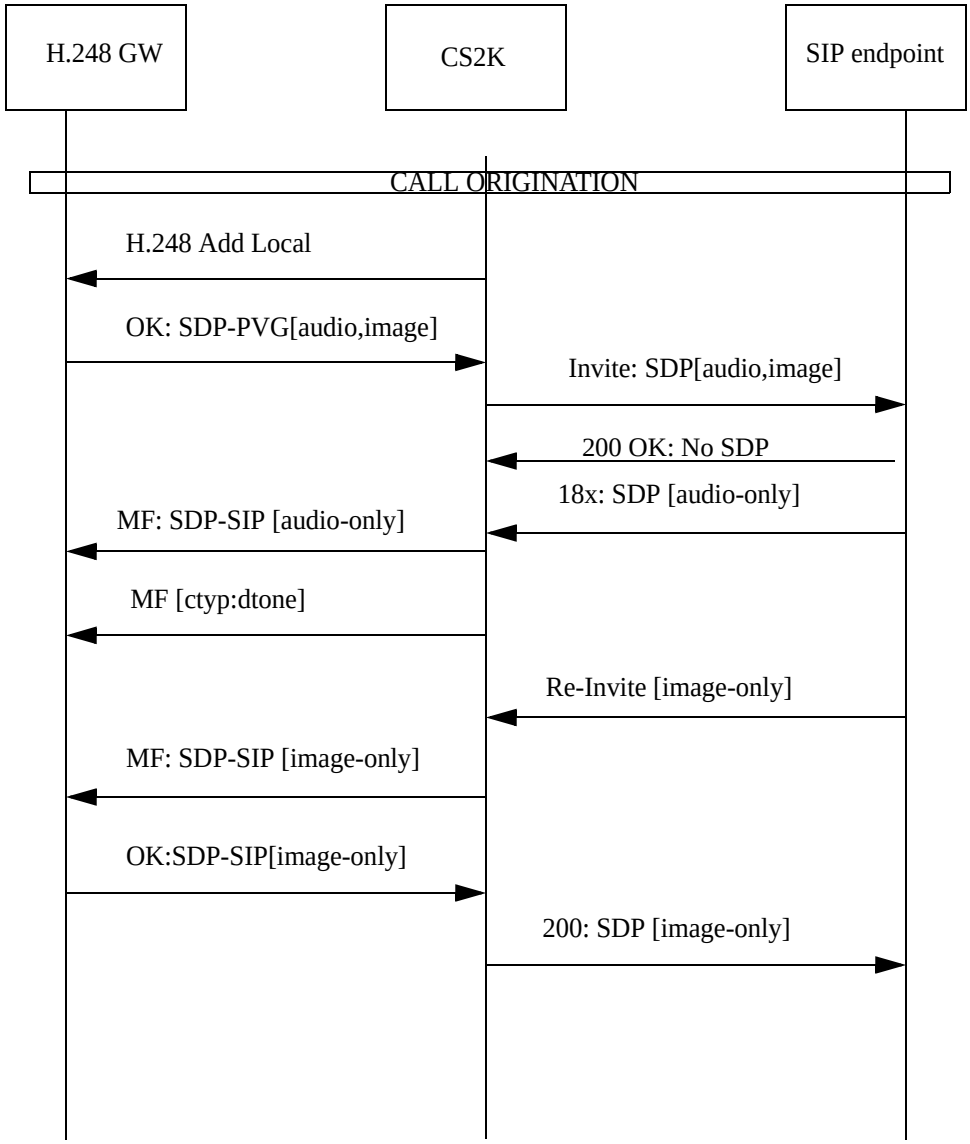
Figure 7 T.38 Calls originating from CISCO/MTS and terminating at PVG on CS2K



55.2.5.2 Basic Call Scenario: PVG to SIP interworking.

When a call is originating from PVG, a SIP INVITE is sent from CS2K to the SIP Endpoint which replies with its SDP. And a voice call is established successfully. After this a V.21 Fax notify is sent from the receiving gateway. This triggers a change in the codec from G.711 or G.729 to T.38 (If T.38 flag is set in netopts).

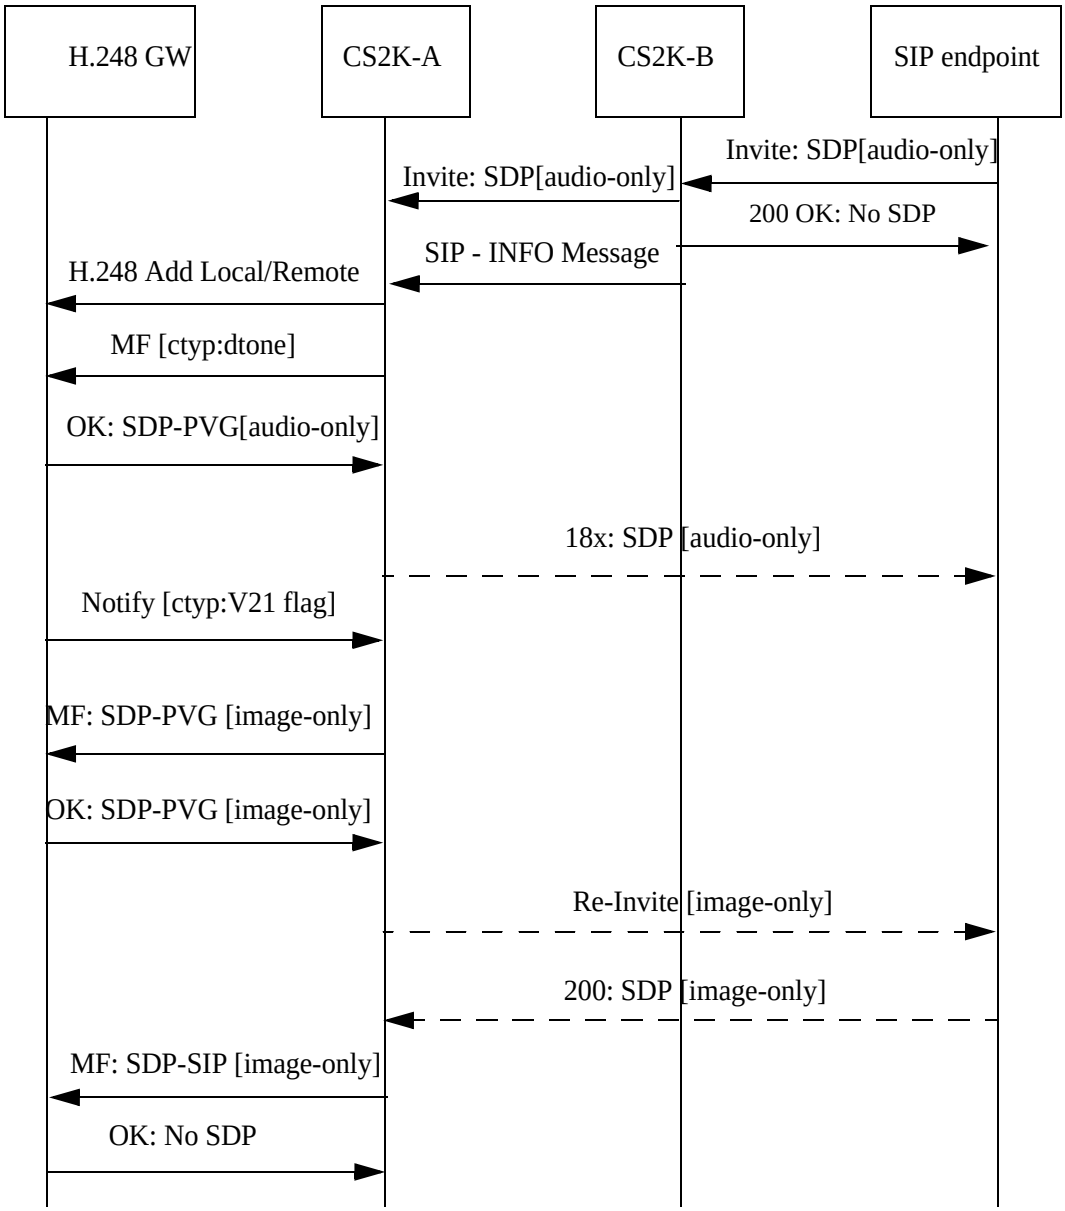
Figure 8 T.38 Calls originating from PVG on CS2K and terminating at CISCO/ MTS



55.2.5.3 Tandeming Support

SIP INFO message will be used when CS2Ks are in tandem to support T.38 Annex D interworking.In the figure below CS2K-B acts a TANDEM CS2K. If T.38 is provisioned on the NGSS of CS2K-B then it required to instruct CS2K-A to start scanning for fax tone from PVG. SIP INFO message will be used for this purpose.

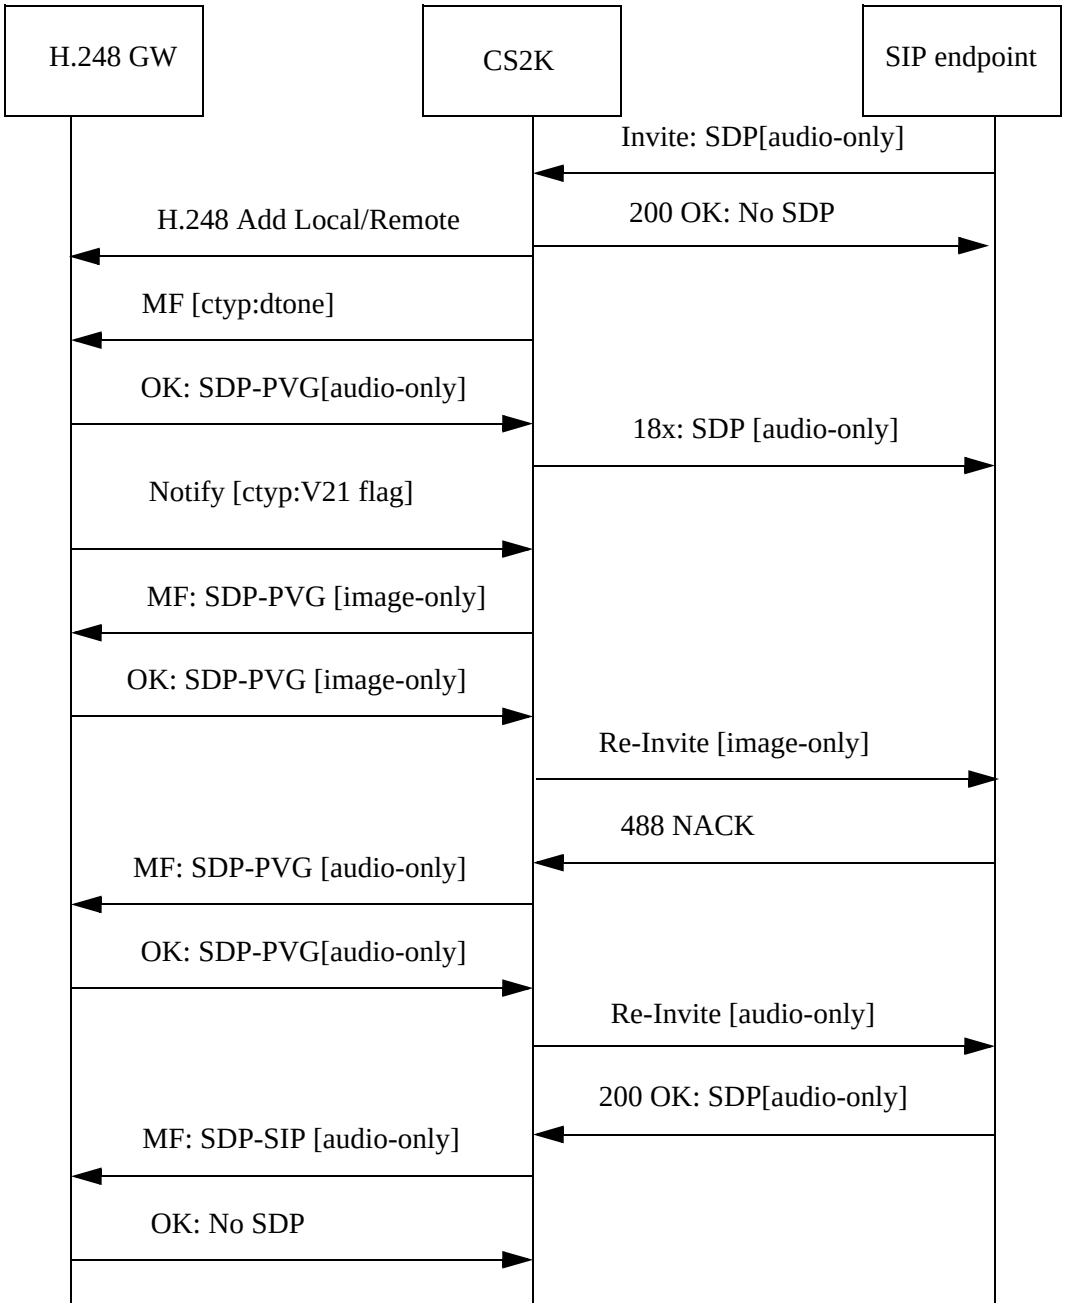
Figure 9 T.38 Fax calls spanning over more than one CS2K



55.2.5.4 Unsuccessful switch attempt

In a T.38 Fax call when the SIP Re-INVITE for the switch-over from voice to T.38 mode is NACKed, an attempt should be made to save the call by switching back the codec to voice. In such scenario, a SIP Re-INVITE is sent with voice only codec to switch the call back to voice.

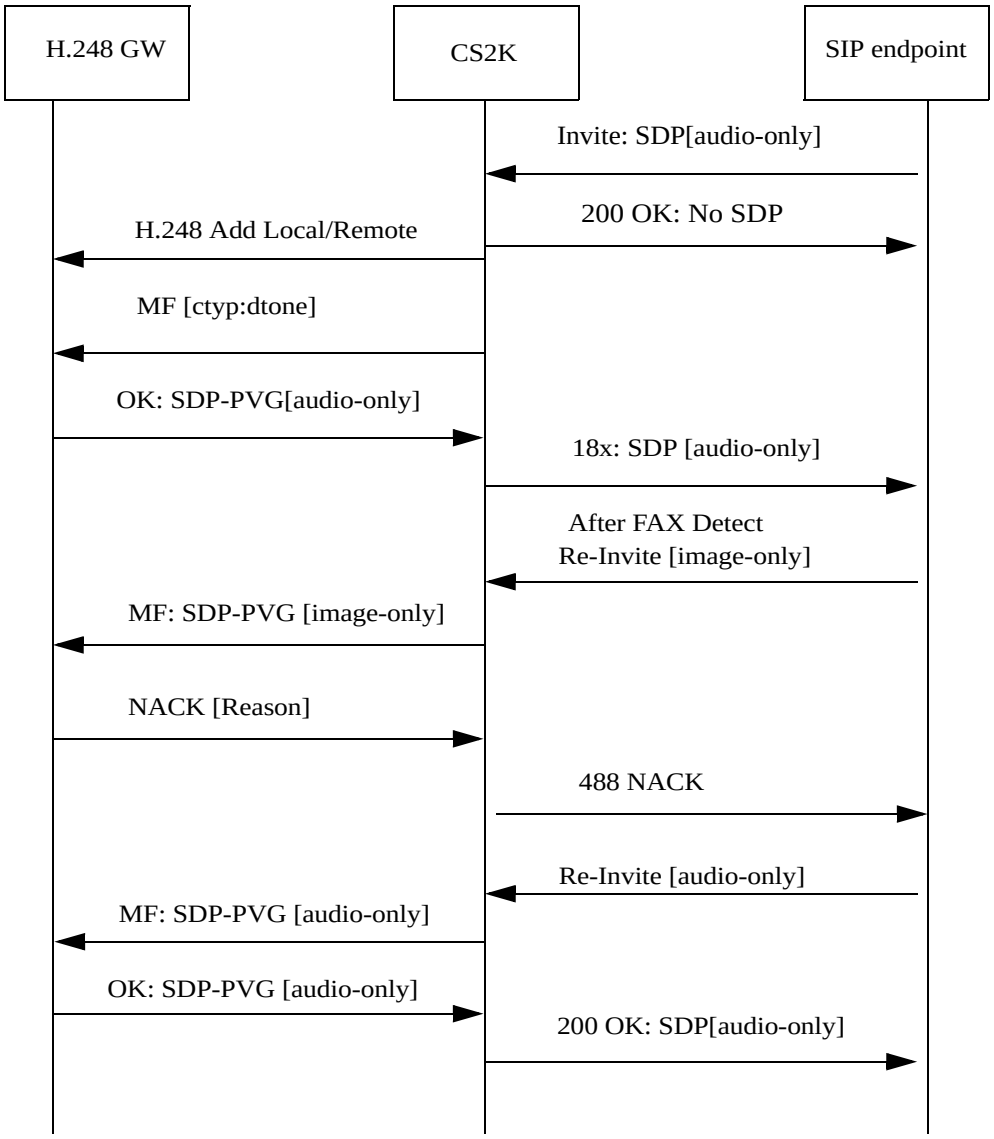
Figure 10 SIP endpoint rejects the Offer



55.2.5.5 Unsuccessful switch attempt

When the SIP Re-INVITE Fax offer for a switch to T.38 comes from the remote SIP side and the PVG NACKS it, the PVG sends the reason for the rejection to the SIP side which in turn sends a SIP Re-INVITE to change the SDPs to audio-only mode.

Figure 11 PVG Rejects Offer



55.3 Hardware Requirements or Dependencies

No New hardware is required.

55.4 Software Requirements or Dependencies

CM/GWC: SN09 load

H.248 GW: supporting H.248.1, H.248.2 ctyp package, T.38 mode.

T.38 should be provisioned both on the H.248 GW and remote SIP side.

55.5 Limitations and restrictions

- "Facsimile-only over IP environment" (T.38 Annex D.2.2.3) is out of scope for this feature. This feature addresses "Facsimile and voice over IP environment" (T.38 Annex D.2.2.4) in which first a voice call is established and then switch over to T.38 mode occurs.
- This feature verifies T.38 Annex D interworking for H.248 GW on one call leg and 3rd party SIP User Agent Server on other call leg. T.38 interworking with other GWs are out of scope for this feature and will not be tested in this feature.
- This feature uses the transport layer UDP/IP for T.38 packets (T.38 Annex D.2.3.2). Transport of T.38 packets via TCP/IP is not used by this feature.
- This feature is being tested only on H.248 PVG. Though it should work fine on H.248 supported gateways, we do not perform testing on other H.248 gateways such as M2K..

55.6 Interactions

Not Identified.

55.7 Glossary

Term	Description
CED	Called terminal identification answer tone of Fax device (2100 +/- 15 Hz, continuous tone, duration 2.6-4.0 sec.) see T.30 chapter 4.1
CM	Call Manager, Computing Modules
CNG	Calling tone of Fax device (1100 +/- 38 Hz, 0.5 sec. on, 3.0 sec. off, duration 60-120 sec.) see T.30 chapter 4.2.

Term	Description
CS2K	Call Server 2000
G3FE	Group 3 Facsimile Equipment G3FE refers to any entity which presents a communication interface conforming to ITU- T Recommendation T. 30, T. 4, and optionally T. 6. A G3FE may be a traditional G3 facsimile machine, an application with a T. 30 protocol engine or any other possibility mention in the network model for IP Facsimile mentioned in Recommendation T. 38.
GW	Gateway (Signalling Gateway and Media Gateway)
GWC	Gateway Controller
MCS	Multimedia Communication Server
PSTN	Public Switched Telephone Network.
PVG	Passport Packet Voice Gateway
RFC	Request For Comments (IETF)
RTP	Real-time Transport Protocol (IETF 1889, 3550)
SDP	Session Description Protocol (IETF RFC 3266)
SIP	Session Initiation Protocol (IETF RFC 3261)
UDP	User Datagram Protocol (IETF RFC 768)
UDPTL	Facsimile UDP Transport Layer protocol (ITU T.38)
V.21 Preamble	Series of flag sequences 01111110 for 1 sec +/- 15%.

56: Functional description (FN): A00009310

56.1 Feature name and Feature ID

SSPFS Restricted Access Shell - A00009310

56.2 Description

This feature's intention is to provide a hardened restricted shell for non-administrative CLUI functions on the SSPFS platform. It is expected that customers will use this environment when giving users access to CLUIs residing on SSPFS servers. The users will have a restricted command set and shell environment, unlike today whereas the user is given an unrestricted shell to run the CLUI utilities.

The restricted shell will use the Solaris resident rksh (restricted Korn shell). With a restricted Korn shell, the user cannot:

- Change the working directory.
- Set the value of SHELL, ENV, or PATH variables.
- Specify the pathname of a command with a '/' in it.
- Redirect output of a command with '>', '>|', '<>', or '>>'.

The only commands available to the user will be those in the PATH variable defined by the user's default .profile. The PATH variable will be made up of the restricted access shell bin directories. The default .profile will be contained in the restricted access shell skeleton directory (/etc/skel.rash).

The application CLUIs (i.e. npm, gwcadmin.sh) currently provide their own level of authentication via the existing login servlet when accessing the CLUI. Within the application, an additional level of command authorization may be used based on the group(s) of the CLUI user. This authorization/ authentication mechanism used by the application CLUIs is functionality that has been in use prior to SN09 and will not be changed by this new content.

At times, a restricted access shell user will need to perform system administrative tasks, which will require root (or other user) access. The restrcited access shell user will be required to 'su' to the new user. This feature provides an 'su' wrapper that verfies the user invoking su is a member of either emsadm or secadm group before gaining access to the Solaris resident 'su' command.

Creating Local Restricted Shell User Accounts

To obtain the functionality of this feature, specify the shell to be '/usr/bin/rash' and the skeleton directory to be./etc/skel.rash'. Restrcited access shell users

wil lhave their home directory created in /export/home/<user id>. If the user is to be created in the restricted shell environment using the Solaris 'useradd' command, specify the '-s' option for shell, '-d' option for home directory, and '-k' option for skeleton directory. The following is an example of creating restricted access user 'test6' using the Solaris useradd command:

useradd -gsuccssn -Gmgcadm,emsadm -s /usr/bin/rash -d /export/home/test6 -m -k /etc/skel.rash test6

From the example above, user id 'test6' will:

- Have a SHELL equal to restricted access shell (rash) which is ultimately rksh.
- Have a home directory at: /export/home/test6
- Home directory will contain the contents of /etc/skel.rash. This is where the user's .profile is obtained which will contain the limited PATH variable containing only restricted bin directories (i.e. /usr/rbin/basebin)..
- User's primary group is succssn.
- User's secondary groups are mgcadm and emsadm.

Creating Central Restricted Shell User Accounts

To grant restricted shell access to a central user account, the users's shell must be set to '/usr/bin/rash' and user's home directory to '/export/home/<usrname>'. If IEMS Security Server is used to manage the central user account, this is done by setting the user's login shell to 'restricted'.

The creation of user home directory /home/export/<usrname> and copying of user shell profile from skeleton directory /etc/skel.rash are automatically handled by a specialized PAM-MKHOMEDIR SPI.

Registering Restricted Access Shell Executables

Applications will use the Servman utility to register restricted access shell executables. Option '-rash' has been added to Servman which will handle creating the links and removing the links within servman.

To add single files, use the restricted access shell option as follows:

servman register -group newapp -*rash "fullpath;name"*

> ***Note:*** Where *name* is the symbolic link name in the restricted shell bin directory and *fullpath* is the path to the actual executable. Servman will create a symbolic link in the application restricted bin directory (i.e. /usr/rbin/appbin).

To add multiple files, us a similar command but delimit the entries with the ‘*’ character:

servman register -group oldapp -rash “fullpath1;name*fullpath2;name2”

Restricted Command Set

Much of what makes the restricted access shell restrictive is the limited command set. This command set will be split into base level commands and application level commands. Base level commands include Solaris resident commands and SSPFS delivered commands. Application commands includes commands installed after SSPFS, such as application CLUIs (i.e. gwcem, sam21em).

Table 1: Solaris and SSPFS Commands

Command	Comment/Usage
awk	pattern scanning
cat	concatenate and display files
cli	SSPFS command line interface, mainly for configuration changes.
cut	cut out selected fields of each line of a file
df	displays number of free disk blocks and files
grep	search a file for a pattern
iostat	report I/O statistics
ipcs	report inter-process communication facilities status
kill	terminate or signal processes
less	browse or page through a text file (
ls	list contents of directory
more	browse or page through a text file
netstat	show network status
ps	report process status

Table 1: Solaris and SSPFS Commands

Command	Comment/Usage
servquery	Query the status of SSPFS applications
sort	sort, merge, or sequence check text files
su	Wrapper that only allows users in group emsadm or secadm to access Solaris su.
top	provide system and process status
head	display first few lines of files
tail	display the last part of a file
vmstat	report virtual memory statistics

Table 2: Application (other) Commands

Command	Comment/Usage
npm	Network Path Manager CLUI
gwcad-min.sh	GatweWay Controller Element Manager CLUI
bpt	Bulk Provisioning Tool
sam21em	SAM21 Element Manager CLUI
?	SNMP Poller - executables needed not provided at this time.
?	OMPUSH - executables needed not provided at this time

Note: Currently, IEMS exposes the following commands to be executed on the SSPFS element in an unrestricted shell, logging in as root user via ssh: *servquery -status all, swact, servstart IEMS, init 6*. IEMS will continue to function in this manner for SN09 as the scope of this feature does not include changing existing “root only” commnads and having them execute in a restricted shell environemnt.

56.3 Hardware Requirements or Dependencies

Not applicable.

56.4 Software Requirements or Dependencies

Not applicable.

56.5 Limitations and restrictions

Not applicable.

56.6 Interactions

First interaction is the change to the shell environment users may get when they are given access to the SSPFS server to invoke maintenance CLUIs. Today, the user is granted an unrestricted shell to access the CLUIs, which gives the user access to other server resources which may not be the desired. This feature restricts the user's environment, limiting the server's exposure to only the user's home directory. In addition, the users PATH will also be limited to directories which contain a subset of available server executables.

57: Functional description (FN): A00009311

57.1 Feature name and Feature ID

SSPFS Dark Office backup - A00009311

57.2 Description

There is a critical need to allow customers to re-write the image and data on to the DVD more than one time without ejecting the DVD tray as it currently is done today. This limits the number of times someone has to go to the central office every time when backing up data is required or to put a DVD into the DVD tray every time its blanked.

With this feature, full system backups are schedulable to both active and inactive units and can re-use the same physical media (DVD-RW only) to rewrite over them. Alarms are raised when backups fail. System image size is limited to 4 Gig. A backup image can be restored to a fresh installed machine. The original media is required for a restore. A restore will either leave the non backed-up filesystems intact or create them if they do not exist.

Figure 1 illustrates a typical backup scenerio of how this feature is used.

- User logs in either as a Super User or through the “Restricted Access Shell” feature in SN09 and be part of the “emsadm” group to have “su” access.
- User uses the SSPFS CLI (CLUI) to invoke the “Backup Configuration” settings menu and schedule a full system backup of the SSPFS box.
- On scheduled date and time, the bkfullsys backup command is called to backup the system and failures are reported northbound.

If the DVD disk is re-writable, no user intervention is required for this operation to happen and depending on what rules are defined for the DVD behavior, the DVD can be re-written over on the scheduled date and time automatically.

Three simple rules can be invoked through the “Backup Configuration” to define the backup behavior.

1 - When performing backup, eject DVD tray when done.

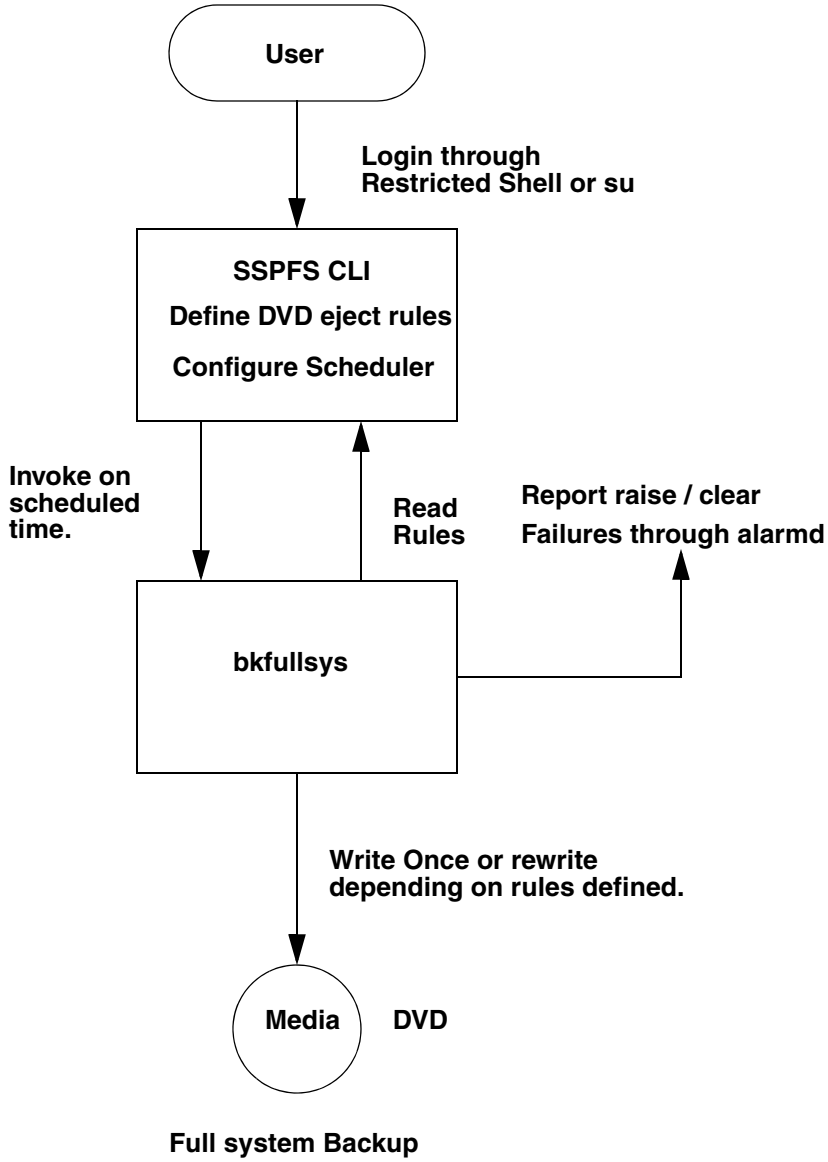
2 - When performing backup, do not eject DVD tray , subsequent backups will not overwrite previous data.

3 - When performing backup, do not eject DVD tray, subsequent backups will overwrite previous data.

The backup scripts (bkfullsys and bkdata) will also confirm to these rules if invoked manually, option 1 is default setting.

For backing up critical data which includes Oracle and critical application data, this feature provides you with an option that can be invoked through the "Backup Configuration" in SSPFS CLI called "***Copy last Oracle backup to DVD or tape".*** This option will copy the last good Oracle backup from the "Syncronized Backup Manager" and burn it to DVD or tape. The "Syncronized Backup Manager" has its own scheduler for backing up the critical data at scheduled intervals and writes to disk. This option does not do the backup itself, it simply copies what was written to disk by the "Syncronised Backup Manager".

Figure 1: Backup Flow Diagram



57.3 Hardware Requirements or Dependencies

Not applicable

57.4 Software Requirements or Dependencies

Not applicable

57.5 Limitations and restrictions

Backup and Restore time will dependent on the I/O speed to the target media whether it is hard drive, tape drive, or DVD / CD burner.

57.6 Interactions

This feature interacts with the SSPFS backup and restore scripts for doing a full system backup and backing up of oracle and critical data that are part of the" Backup and Restore Enhancements" feature in SN09 which is called at scheduled intervals by the "Syncronised Backup Manager" which was first introduced in SN08.

This feature also interacts with the "Restricted Access Shell" feature to be able to schedule backups in a restricted shell environment.

58.1 Feature name and Feature ID

SSPFS SN09 Upgrades and ESD Support - A00009313

58.2 Description

This feature will cover the SSPFS upgrade from SN07, or SN08 to the SN09 SSPFS release. The goal of this feature is primarily two areas: ESD support and greater robustness. The intent is to upgrade SSPFS with a minimal of application downtime.

58.3 Design Component: ESD SSPFS SN09 Upgrade

It is very important to set the expectations of this feature. The goal of this feature is to provide SSPFS upgrades using electronic delivery of the ISO images instead of physical cdrom media.

The pre_upgrade.ksh upgrade script of SSPFS creates the location /Upgrade which is the repository for the iso images. After execution of the pre_upgrade script, the user is to place all 3 disk images in the /Upgrade directory. If they all exist, the user will be prompted as to whether or not they intend to perform an ESD upgrade. If they respond positively, then the upgrade will begin in a similar fashion to the normal upgrade. However, the main difference is that the user will never be prompted for the insertion of the SSPFS cdrom disks. Therefore, it will continue unassisted until near the end of the SSPFS upgrade. There will be one point on cbm profiles, where the SSPFS upgrade will stop and we will prompt the user to upgrade the CBM application. Lastly, the user must choose to accept the upgrade or fallback just like the normal upgrade.

58.4 Design Component: pre_upgrade.ksh improvements

This design component is just being developed to document changes which will be placed into the pre_upgrade.ksh script for robustness.The pre_upgrade.ksh upgrade script of SSPFS will be enhanced to check the following additional system states prior to full upgrade execution:

- Ensure the required SSPFS disk mirrors exist and have all sub-mirrors attached.
- Ensure that /var has enough free space to hold the package spooling during the upgrade execution.

These enhancements will allow pre_upgrade to catch more failure cases prior to execution of the main upgrade script. Therefore, the user has a chance to fix system errors before attempting the upgrade again.

59: Functional description (FN): A00009315

59.1 Feature name and Feature ID

Detect failures from syslog and generate alarms - A00009315

59.2 Description

Detect if the syslog system has failed to write logs and raise a major alarm. If and when the syslog system becomes operational, the alarm will be cleared.

Failure detection is not done on each write to the syslog stream, thus it's not 100% real-time. A ten minute audit is used instead. If the audit fails it will wait for one more failing audit before the alarm is raised.

The default timing interval for checking that the logs have stopped is 10 minutes. If a log was generated within the last 10 minutes then everything is working. If the log is older than 10 minutes the system will allow one more 10 minute interval to pass before rasing an alarm. The fastest that an alarm will be raised is 21 minutes and the slowest is 29 minutes.

Note, the timing interval is fixed and cannot be changed by the customer.

This facility will be provided on all profiles of SSPFS-based products, including CMT, MG9K EM, IEMS, MDM, and CBM.

The Fault Management section identifies the details of the new alarm.

59.3 Hardware Requirements or Dependencies

Not applicable.

59.4 Software Requirements or Dependencies

Not applicable.

59.5 Limitations and restrictions

Does not monitor each syslog write in real-time, and does not ensure reliable forwarding of syslog messages to a remote syslog daemon.

60: Functional description (FN): A00009316

60.1 Feature name and Feature ID

Backup and Restore Enhancements (A00009316)

60.2 Description

This feature's intention is to improve the speed of the SSPFS backup and restore of application data. This backup includes the data stored in the Oracle database and the files registered by applications for backup.

The end user backs up data to disk, tape, or DVD with the following two simple commands. Every effort will be made to preserve the same interface.

/opt/nortel/sspfs/bks/bkdata [-f filename]

/opt/nortel/sspfs/bks/rsdata [-f filename]

The introduction of IEMS to the Succession Solution has increased the amount of data stored in the Oracle database dramatically. The amount of data has made the restore take more than 30 minutes. The majority of the data is alarm, event histories, and peformance metrics. IEMS has made an effort to separate this data from the configuration data with the intention of only backing up the configuration data.

The current interface that applications use to register information in SSPFS is called SERVMAN. This feature will require changes to SERVMAN to allow applications to specify portions of data to exclude/include from the backup/ restore process.

New options in SERVMAN will allow the applications to register, deregister, and query a list of Oracle tablespace names to exclude from the backup/restore process. These commands are not intended for end users, they are intended to be called from application install scripts.

Use servman with register, deregister or query

servman register <-g Group> [-s startScript] [-t stopScript]

[-d dependsString] [-e healthScript]

[-p portInfo] [-f filesystem] [-k critData]

[-bem bkupEnableDataModsScript] [-bdm bkupDisableDataModsScript]

[-bcd bkupCritDataScript] [-bms bkupModeStatusScript]

[-bpc bkupPreCheckScript] [-tbs tablespace]

servman deregister <-g Group>

servman query <-registered | -status | -backup>

< <all | all -tbs | -group <groupName> | <-group <groupName> -bem | -bdm | -bcd | -bms | -bpc | -tbs> > <-v>

60.3 Hardware Requirements or Dependencies

No specific hardware requirements. But there will be a need for a new dedicated disk space for backups of the Oracle database and any files registered as critical files by applications. This space needs are bound by existing hardware specs for the Sun Netra T1400 and the Sun Netra 240.

60.4 Software Requirements or Dependencies

No new software requirements. However, a feature of Oracle called Recovery Manager (RMAN) may be utilitized for the first time.

60.5 Limitations and restrictions

Backup and Restore time will always be bound by I/O speed to the target media whether it is a hard drive, tape drive, or DVD/CD burner.

60.6 Interactions

The changes in this feature interacts with the “Synchronized Backup Manager”. This Backup Manager was introduced in SN08 and calls the SSPFS backup scripts at scheduled intervals.

61: Functional description (FN): A00009320

61.1 Feature name and Feature ID

A00009320, A00009336 - Remote Ping and Traceroute for Gateway Controller and SSPFS Platforms

61.2 Description

The purpose of this feature is to provide a centralized, graphical user interface on IEMS to allow users to launch ping and traceroute operations remotely on the Gateway Controller (GWC) and SSPFS platforms; including IEMS, CMT, MG9K Manager and CBM. This addresses the concerns of allowing non-root users access to these potentially harmful commands.

61.3 Hardware Requirements or Dependencies

This feature has no HA dependencies, so any customer-supported hardware configuration will provide a valid IT platform

IEMS Server: T1400, N240 (cluster or simplex)

CMT: T1400, N240 (cluster or simplex)

GWC - any supported hardware

61.4 Software Requirements or Dependencies

IEMS SN09 combo load week 11 or later

CMT - SN09

GWC - SN09 week 11 or later (gn090ap or later)

SSPFS - SN09 week 10 or later

61.5 Limitations and restrictions

This feature provides a centralized interface to the native ping and traceroute functionality on remote platforms. Command options and behavior for ping and traceroute may vary between remote launch points.

Central account users requiring SSPFS remote ping/traceroute capability must be granted restricted platform access (by setting their default shells to `restricted-access shell'.

61.6 Interactions

Remote command launch allows users to troubleshoot network connectivity problems from a single location using the same user interface. It initiates an operation on a remote platform or device as if the user had logged on to the device and issued the command himself. In SN09, remote ping and traceroute functionality has been provided through the IEMS GUI client. These remote operations are supported in this release for the GWC and SSPFS platforms.

This feature adds two new launch menu buttons to the GWC and the SSPFS platform managed objects in the IEMS GUI: one for remote ping, and one for traceroute.

61.6.1 Setup

The following configuration steps must be performed from the SAM21-EM to allow direct IEMS communications with GWCs:

1. Login to the SAM21-EM GUI
2. Click on the “Configuration” menu.
3. Select "Subnet Level Configuration"
4. Enter IEMS virtual IP in "MIB Reader (optional)" text box.
5. Click "Save"

Figure 1 SAM21-EM Configuration menu

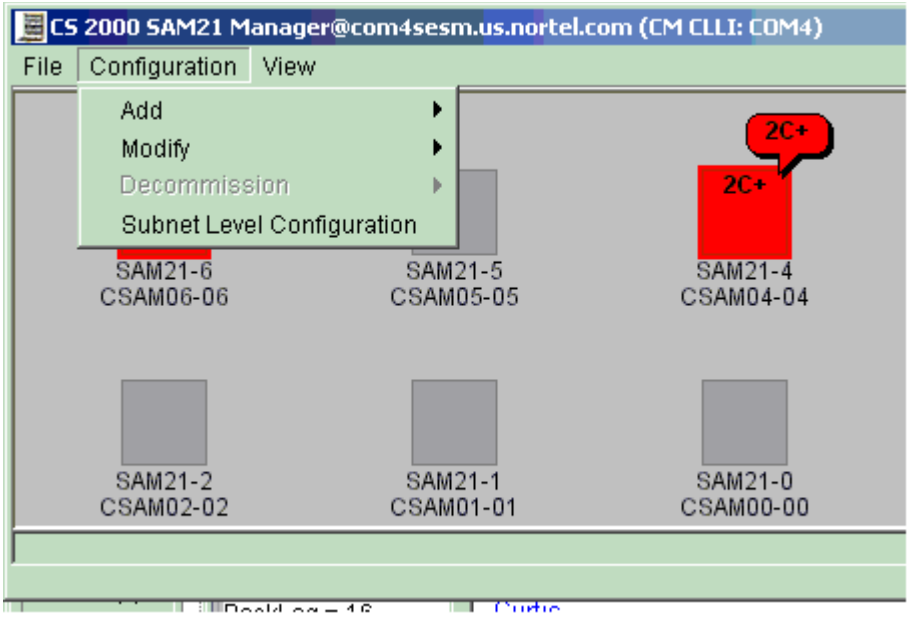

Figure 2 SAM21-EM Subnet Configuration menu

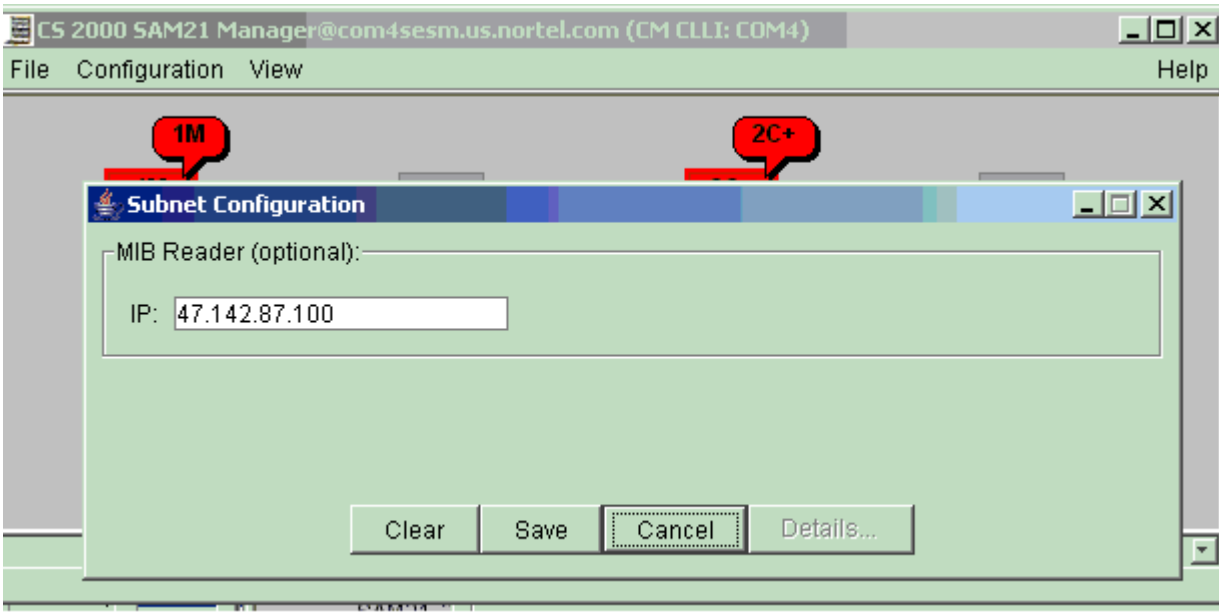

61.6.2 Launching:

This feature is accessed from the drop-down menu available when the a GWC or SSPFS unit managed object is right-clicked. Two new menu items have been added to the list:

- **“Launch Remote Ping”**
- **“Launch Remote TraceRoute”**

Figure 3 GWC Ping/Traceroute Launch Menu

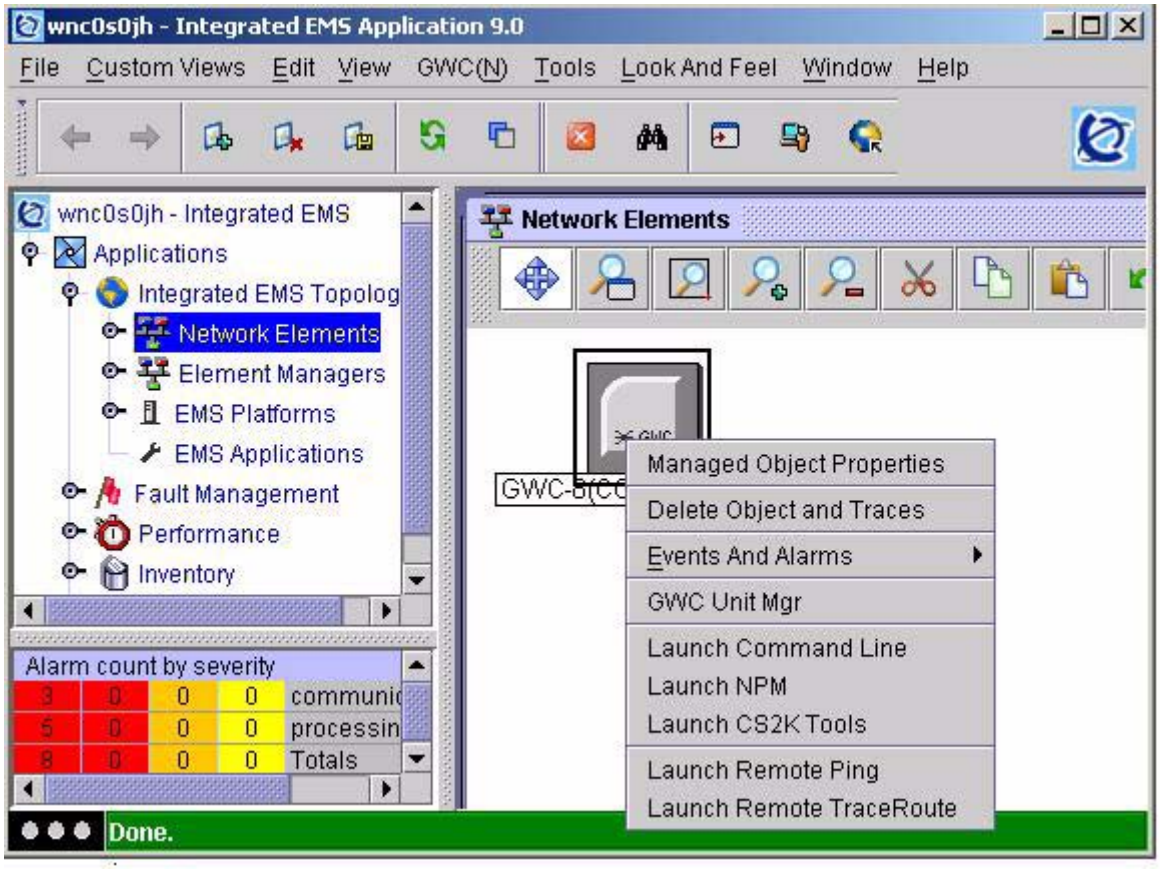

Figure 4 SSPFS Ping/Traceroute Launch Menu

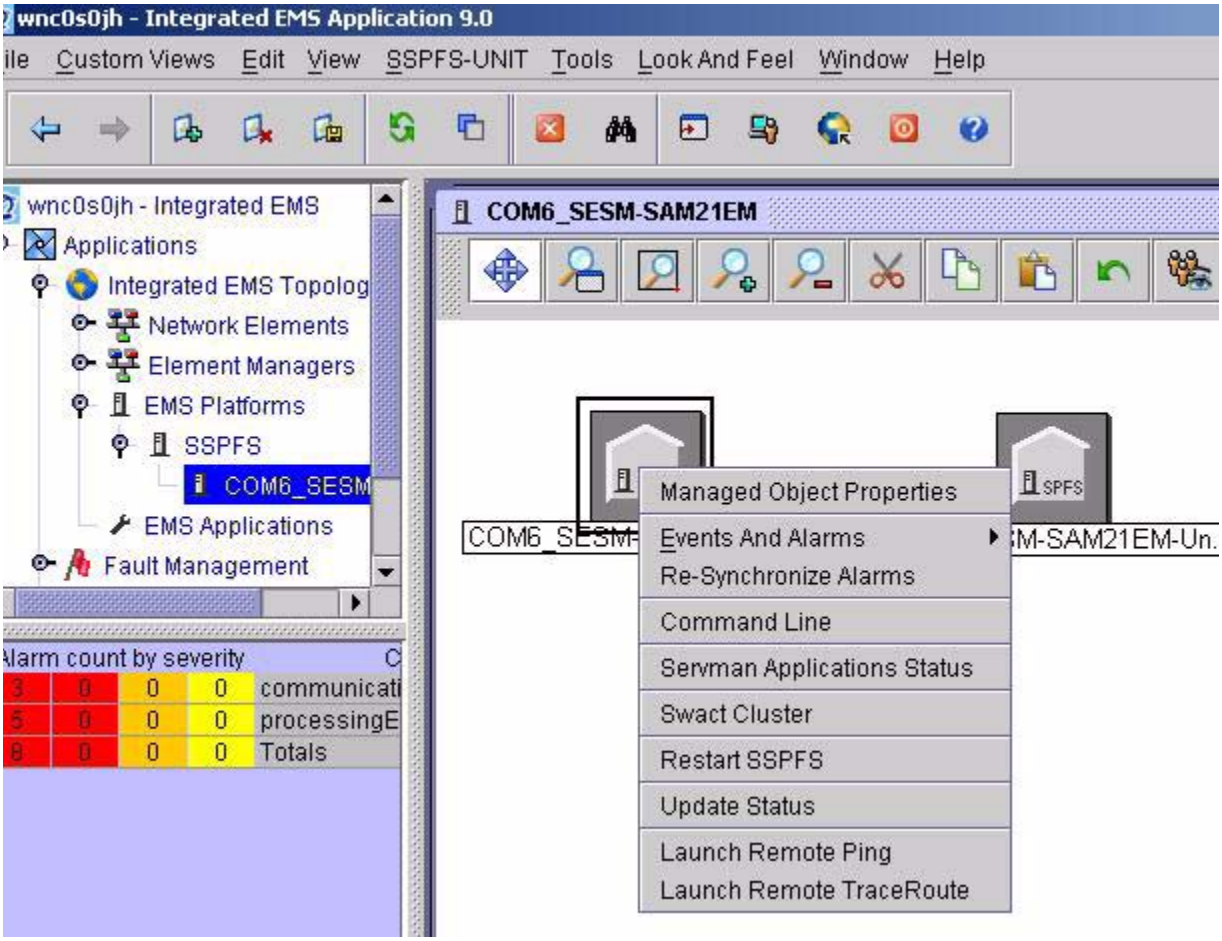


The dialog for either operation is presented when selected from the menu. Each will be discussed in turn.

61.6.2.1 User Authorization

Remote operations are only available to a restricted set of users. For security purposes, only users belonging to one or more of the following groups for supported platforms will have access to these functions: ADM, MTC RW.

The following table lists the groups authorized for remote operations

Table 3: authorization groups for remote operations

SSPFS	GWC
emsadm	mgcadm
emsmtc	mgcmtc

Table 3: authorization groups for remote operations

SSPFS	GWC
emsrw	mgcrw

Remote launch menu options will not appear in the above drop-down menus for unauthorized users.

61.6.2.2 Single Sign-on Support

Once an authorized user has launched a remote operations GUI and entered the required parameters, the command should be sent to the remote host for execution without any further input required by the user. The client will use the security information obtained from the user at initial login , and use this to obtain access to the remote launch host. There is one exception to this rule:

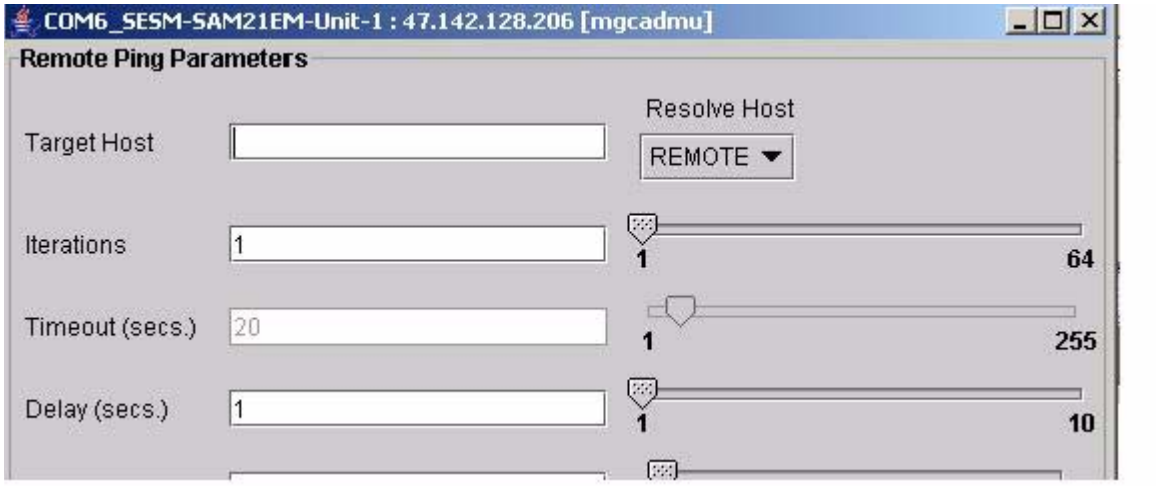
When configured for CBM, the SSPFS platform does not integrate its security with the central security services used to provide single sign-on capabilities to users. In this case, the user will be presented with a dialog prompting for a username and a password to allow remote execution of the ping/traceroute command on the CBM platform.

61.6.3 Notes on Remote Operations:

- only one remote operation (ping or traceroute) is permitted on each managed object at a time. This effectively denies concurrent requests on the same device or platform. For example, user A launches a ping command on GWC 13. User B will be unable to launch any command on GWC 13 until the command completes for user A.
- The RemoteOps interface is constrained by the actual ping and traceroute functionality provided by a remote device. The interface acts as a proxy and invokes the command from the remote host as if a user had logged on and run it manually. Supported values and their ranges may vary between devices. Although a generic set of options, defaults, and ranges have been defined to constrain these operations in the network, they may be constrained even further by the remote host. The supported parameters and ranges for each device will be shown on the client screens when presented for input. The user does not need to know about this. An example of this is packet size. SSPFS platforms support a range of 1-65507 bytes, while the GWC only supports 4-1472 byes. Each range will be automatically enforced on client invocation.
- Ping and traceroute user parameters are common across all device and platform types. If a parameter is unsupported or unconfigurable for a selected managed object, the option will be displayed as read-only with a default value specified (if supported). For example, the screen in Figure 3

displays the ***Delay*** parameter as Read-Only. The value shown will be used for the operation and cannot be changed by the user.

Figure 5 Read-Only Parameter example



Title Bar - The displayName and ipAddress properties of the managed object on the IEMS GUI are displayed in the top left corner of the screen. This is the source host for the remote operation (IP address of object right-clicked on GUI). Following the host infomation is the login user name enclosed in square brackets.

Figure 6 Remote Host Identifier

61.6.4 Remote Ping

The main screen for remote ping allows the user to set the following parameters:

Target Host:

This is the destination host to be ping'ed by the remote platform (GWC , for example). This value can be specified as a host name or IP address (see notes on DNS resolution).

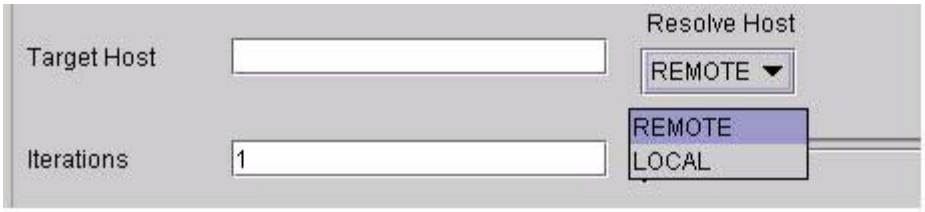
DNS Resolution

- specifies whether target address resolution should be attempted using the name service configured for IEMS server (*LOCAL*), or the name service of the remote launch host (*REMOTE*). This setting defaults to *REMOTE*.

Note: If DNS is not used in the network, then an attempt will be made to resolve the host name or IP using the default resolver on the IEMS server or remote device/platform.

Limitation: When using the "*REMOTE*" option on the GWC platform, target hosts MUST be entered as fully qualified domain names (FQDN). Host names provided without the full domain component will *fail* DNS resolution in the GWC. Target hosts can be specified this way by selecting "*LOCAL*" DNS resolution.

Figure 7 DNS Resolution Options



Iterations:

Specifies how many times to repeat the command.

Timeout:

Specifies the timeout for the remote host to use when running the remote operation. This value is given in seconds.

Delay:

Specifies the delay to use between each ping operation (ie: pause between iterations). This is given in seconds.

Packet Size:

Specifies (in bytes) the data size of each ping probe packet to use in the operation.

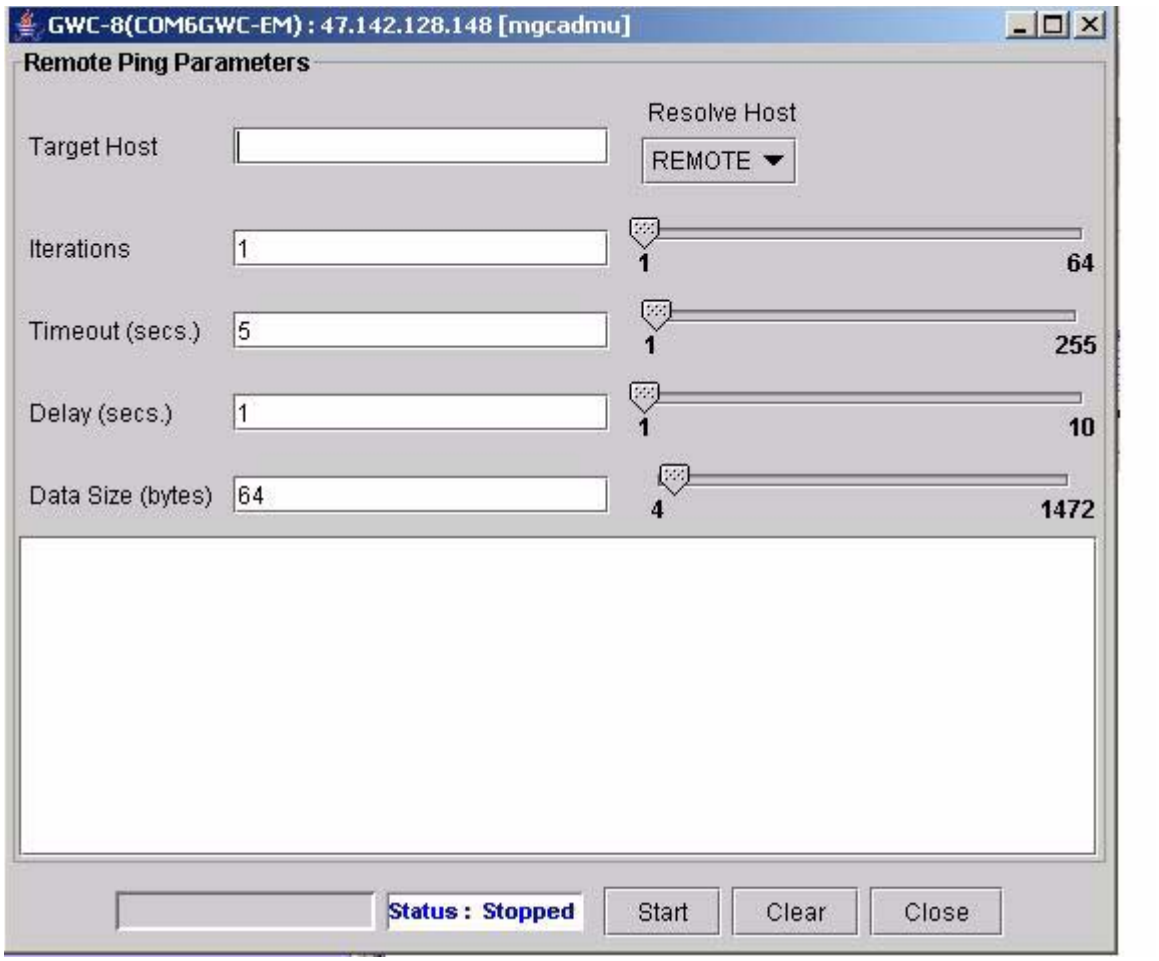
Table 1 Ping Dialog User Parameters

User Parameter	GWC Values	SSPFS Values	Default
Target IP	Host Name or IP address	Host Name or IP address	none
Iterations	1-64	1-64	1

Table 1 Ping Dialog User Parameters

User Parameter	GWC Values	SSPFS Values	Default
Delay (seconds)	1-10	1-10	1
Timeout (seconds)	1-255	1-255	5
DNS Resolution	local/remote	local/remote	remote
Packet size	4-1472 bytes	1-65507 bytes	64 bytes

Figure 8 Remote Ping Launch Screen



Start button

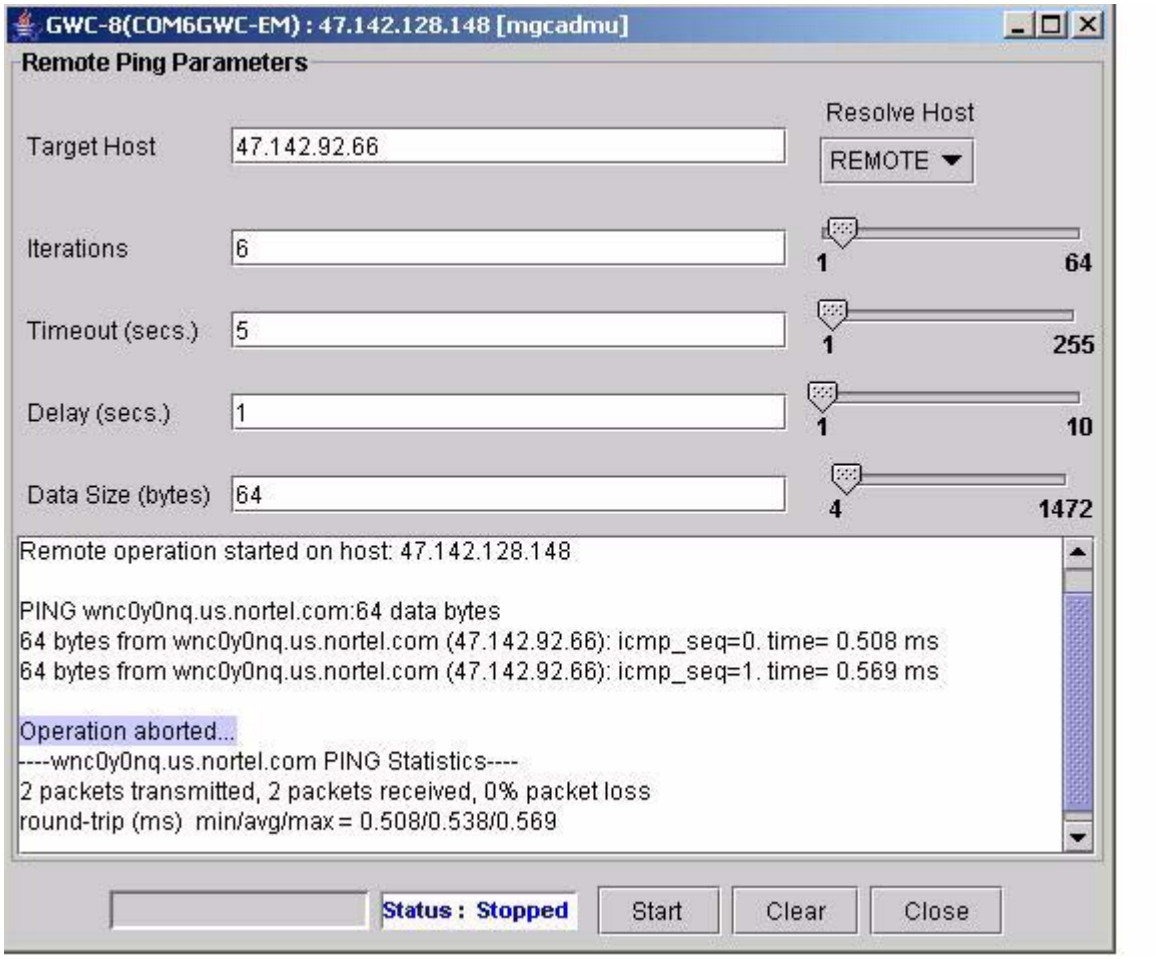
61.6.4.1 Command ABORT

Running commands can be cancelled by the user by clicking the “Stop” button while the status bar indicates “Running”. The command will terminate and provide statistics for the packets sent and received up to the point of

cancellation. The text output provides a message indicating the command was aborted.

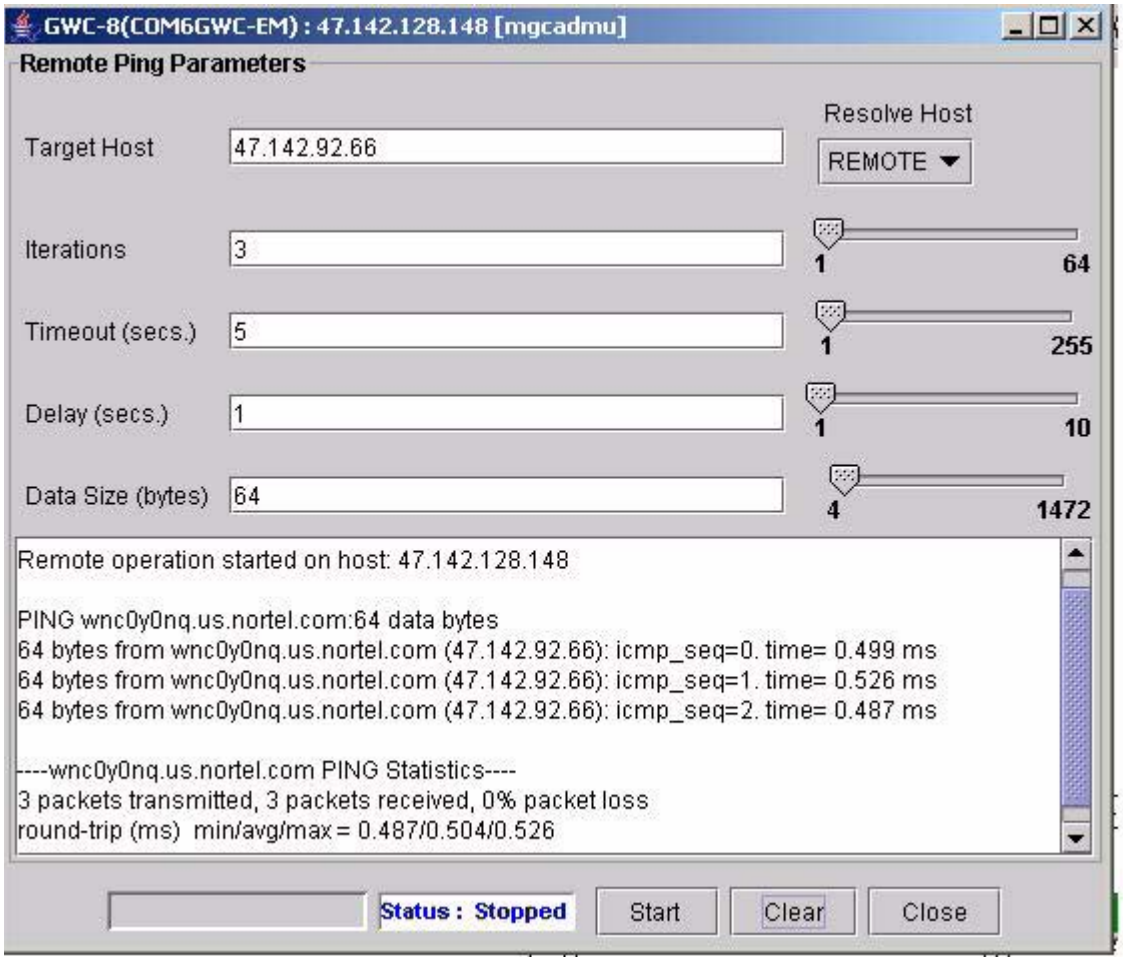
Figure 10 Cancel remote Ping Operation



61.6.4.2 Command output

The response output for the requested command will be output to the text window similar to that show shown in Figure 8. The application communicates with the GWC over SNMP and formats the results to appear similar to UNIX command line ping output :

Figure 11 Ping output Screen



61.6.5 Remote TraceRoute

The main screen for remote ping allows the user to set the following parameters:

Target Host:

This is the destination host to find a route by the remote platform (GWC , for example). This value can be specified as a host name or IP address (see notes on DNS resolution).

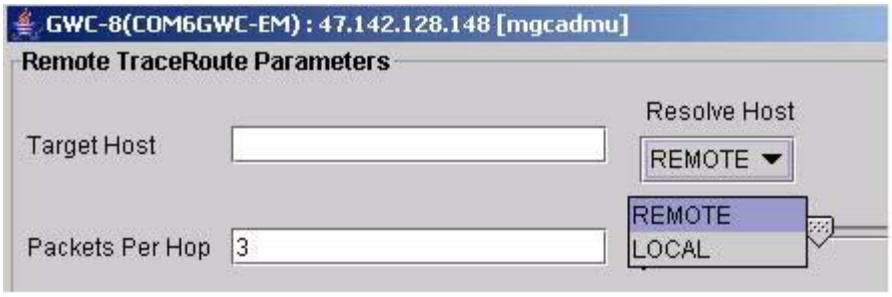
DNS Resolution

- specifies whether target address resolution should be attempted using the name service configured for IEMS server (*LOCAL*), or the name service of the remote launch host (*REMOTE*). This setting defaults to *REMOTE*.

Note: If DNS is not used in the network, then an attempt will be made to resolve the host name or IP using the default resolver on the IEMS server or remote device/platform.

Limitation: When using the "*REMOTE*" option on the GWC platform, target hosts MUST be entered as fully qualified domain names (FQDN). Host names provided without the full domain component will *fail* DNS resolution in the GWC. Target hosts can be specified this way by selecting "*LOCAL*" DNS resolution.

Figure 12 DNS Resolution Options



Timeout:

Specifies the timeout for the remote host to use when running the remote operation. This value is given in seconds.

Packet Size:

Specifies (in bytes) the data size of each ping probe packet to use in the operation.

Table 2 Traceroute Dialog User Parameters

User Parameter	GWC Values	SSPFS Values	Default
Target IP	Host Name or IP address	Host Name or IP address	none
Probes per Hop	1-6	1-6	3
TTL (Time To Live)	1-99	1-99	60
Timeout (seconds)	1-255	1-255	5
DNS Resolution	local/remote	local/remote	remote

62: Functional description (FN): A00009332

62.1 Feature name and Feature ID

The name of the feature is “P-Time and Codec Negotiation Selection Policy”. The feature-ID is A00009332.

62.2 Description

This feature makes enhancements to the CS2M that allows the customer to choose codecs and packetization rates for IP and aal2 network bearer connections that were previously not available. The new P-times are p30ms and p40ms.

The CS2M now supports the following new codecs.

- G.723
- EVRC
- EVRC0
- G726-32
- ILBC
- BV16
- AMR
- G726-24

In addition to the above, further enhancements were made to the CS2M GUI. These enhancements were to display G.711A as PCMA and G.711U as PCMU.

Note: Codec ILBC should only be associated with packetization rates of 20ms or 30ms.

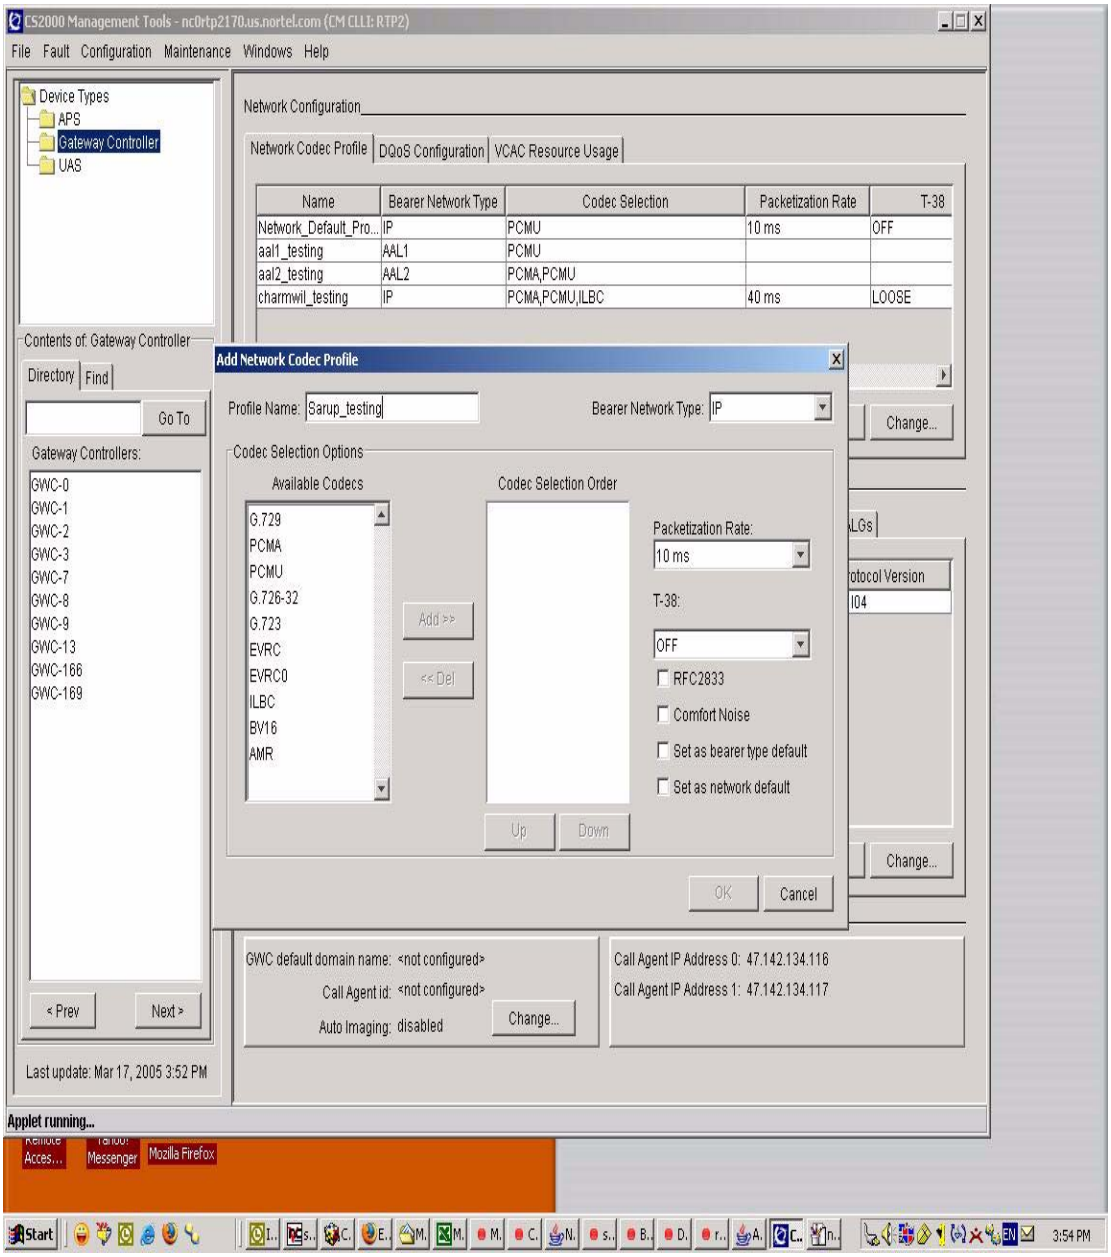
62.3 CS2M GUI Functionality Modifications

2.3.1 Add Network Profile Dialog

When adding a new network profile, the customer could choose three of the eleven codecs listed in the text area. Whatever combination of three that the customer chooses, that combination must include PCMA or PCMU.

The customer can choose from one to maximum of three codecs to provision within their network. Figure one shows the “Add Network Profile Dialog” screen that listed a subset of the codecs the CS2M support.

figure one: Add Network Profile Dialog

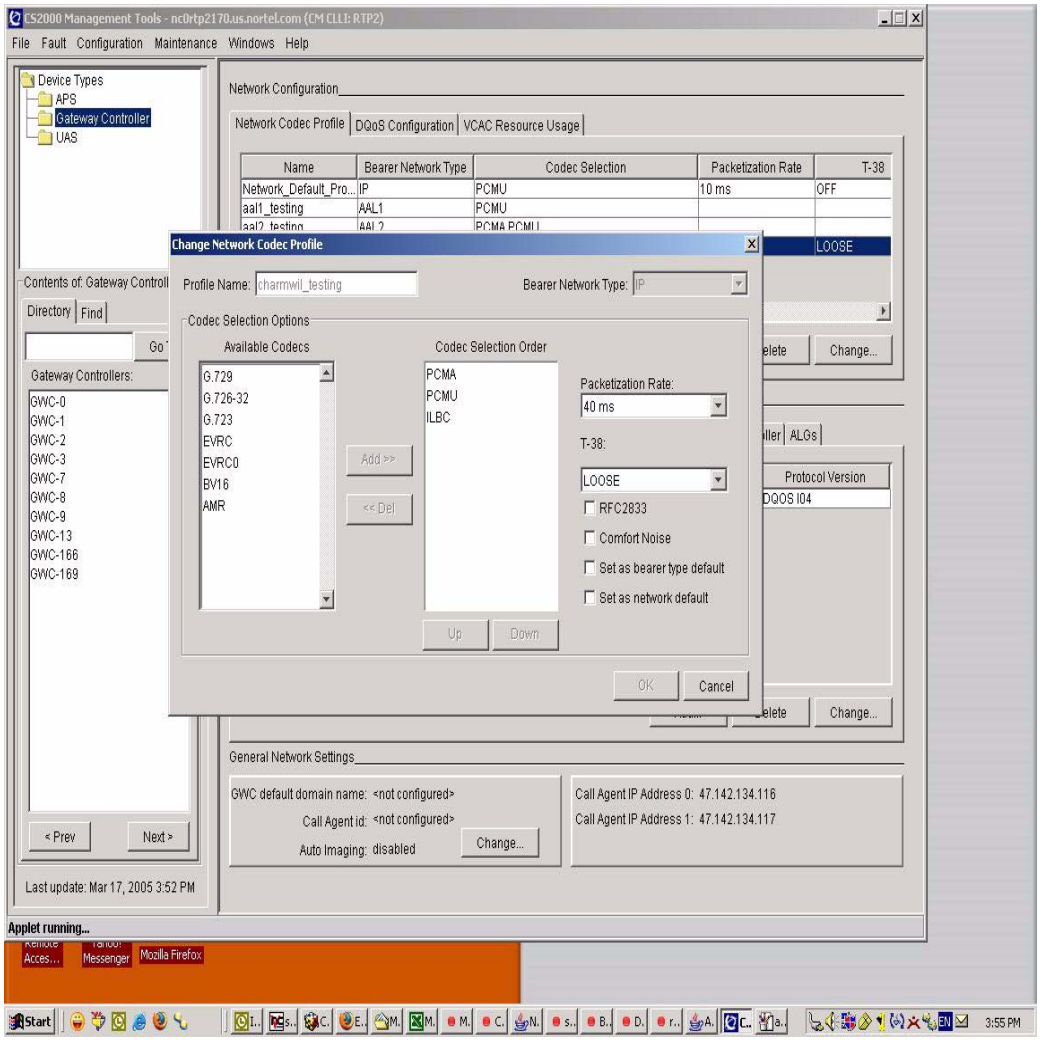


2.3.2 Change Network Profile Dialog

When changing the Network profile, the customer can now select from eleven codecs shown in the selection listing area. Figure two shows the “Change Network Profile Dialog” screen which allows the user to change their previous selection/s.

Note: The same restriction stated in “Add Network Profile Dialog” section applies here.

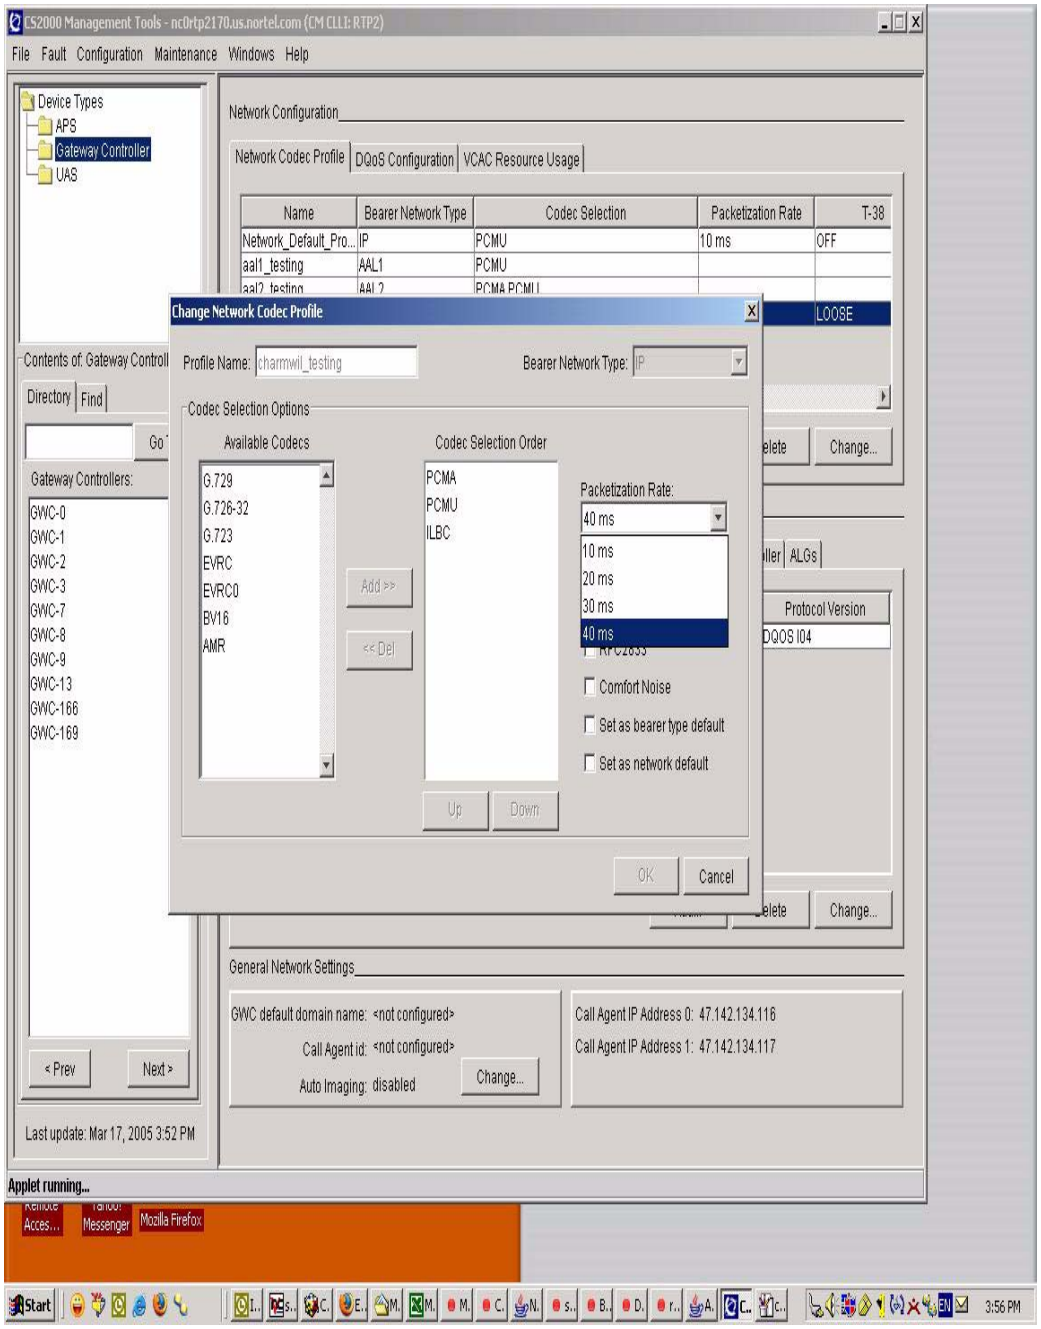
Figure 2: Change Network Profile Dialog



2.3.3 Add P-time Dialog

The customer can now select from four p-times. The p-times are p10ms, p20ms, p30ms and p40ms. Figure 3 shows the screen image of the P-time menu.

Figure 3: Add P-time Dialog Menu



62.4 Hardware Requirements or Dependencies

None.

62.5 Software Requirements or Dependencies

None.

62.6 Limitations and restrictions

- The maximum number of codecs the user is allowed to select is three.
- The user’s selection/s must always include PCMA or PCMU.

62.7 Interactions

None.

CS2M	CS2K Mangement Tool

63: Functional description (FN): A00009337

63.1 Feature name and Feature ID

A00009337 PacketCable 1.0, 1.1, and 1.5 Compliance

63.2 Description

This activity addresses NCS and TGCP ECN support and development items for the Media Gateway Controller (MGC) to satisfy PacketCable1.5 Specifications PKT-SP-NCS1.5-I01-050128 and PKT-SP-TGCP1.5-I01-050128.

Excluded from this activity are:

- T.38 ECNs NCS1.5-S-I01.05-2-Atkinson and TGCP1.5-S-I01.04-2-Hancock, being addressed under activity A00009339 (PC 1.5 Support for T.38 Fax);

In addition, NCS and TGCP PacketCable 1.0 and 1.1 ECN compliance items and Succession solutions development items are included in the activity, and provide Certification Wave 37-aligned PacketCable specification compliance.

Some of the new items being developed in this feature are also being applied via ECN to the PacketCable 1.0 and 1.1 specifications. In these cases, the language is the same as the PC 1.5 ECN's, so the content being addressed in this feature will make the CS2K compliant to 1.0, 1.1, and 1.5 versions of these changes.

Operator services such as Operator Ringback, Operator Recall, Busy Line Verification (BLV), and Barge-In (BI) are now supported over TGCP OP trunks for hybrid office solutions.

For further information regarding MGC support of TGCP trunks, please refer to activities A00003630 (TGCP for the Cable Market) and A00007114 (TGCP Compliancy).

63.3 Hardware Requirements or Dependencies

Not Applicable

63.4 Software Requirements or Dependencies

- The PacketCable TGCP specification does not currently provide any explicit mechanism for an MGC to proactively acquire an endpoint's service state

(when it is necessary to distinguish between in-service and out-of-service endpoints). Until the TGCP specification allows such a mechanism, TGCP gateways MUST only include in-service endpoints within the EndPoint-IdList parameter in response to a CS2000 AuditEndpoint command.

63.5 Limitations and restrictions

- Operator recall over TGCP OP trunks provisioned with TERMHOLD is supported for both circuit-switched and packet-switched lines, if onhook/offhook (ie. suspend/resume) transition is performed via switchhook. Operator recall cannot be initiated with flash key for packet-switched lines.

64: Functional description (FN): A00009339

64.1 Feature name and Feature ID

Packet Cable T.38 Support, activity A00009339.

64.2 Description

This activity provides packet cable support for T.38 Fax based on PacketCable1.5 Specifications. It adds T.38 fax element into the LCO (for NCS and TGCP) which is sent to the gateway at the start of a call. The presence of this information triggers the gateway to include the T.38 into its SDP response. This is then used by the far end gateway to ensure that both gateways support T.38 before the functionality is used.

This activity provides T.38 support which is compliant with the PacketCable 1.5 Specifications.

The switch-over to T.38 is performed based on the MTA or MG sending a detection of the “t38 start” event. If the T.38 codec is supported by both gateways, the call switches to T.38 mode once the switching sequence completes.

This feature will implement T.38 strict and loose modes, as described in the PacketCable 1.5 Specifications. If strict mode is active, the attempt to switch to T.38 codec will only occur if both gateways in the call advertise T.38 capabilities in their SDP (refer to the CS2000 T.38 Gateway Interoperability Specification for details). If loose mode is active, the CS2000 will attempt to switch to T.38 even if one side does not advertise T.38 capabilities. In loose mode, when the codec switch is rejected by either end, an attempt will be made to preserve the call by switching back to G.711 codec.

> ***Note:*** Prior to SN09, the only choice for T.38 was enabled or disabled. The equivalent for “enabled” is “strict” mode in SN09.

Strict Mode is recommended to be used if all Gateways in a customer network support T.38. Due to increased messaging, Loose Mode is only recommended when there are gateways in the network that (1) support the T.38 codec, and (2) do not advertise this support in the SDP. This scenario is common when SIP trunks are being used, but is unlikely when a customer has exclusively PacketCable 1.5-compliant devices and/or a T.38-capable PVG.

Loose Mode is not recommended to be used during an SN09 upgrade while Gateways are being upgraded to T.38-capable loads. Instead, it is recommended to leave T.38 off until all Gateways have been upgraded, then turn it to “strict” or “loose” as appropriate.

The customer must configure T.38 in either “strict”, “loose”, or “off” mode via the GWC Element Manager in CS2M. Since this setting can be different for each GWC, there is a possibility of different modes being applied to each Gateway involved in a FAX call. It is recommended that customers choose the same T.38 mode across all GWC’s. If different modes must be used, the customer must select either “strict” or “loose” across all profiles. T.38 calls are not supported and will fail if any profiles have T.38 configured to the “off” setting.

This feature requires that a non-compression codec (G.711) must always be an alternative in the codec list when one or more compression codecs are used. This provides an alternative to allow the FAX call to succeed in the event that one Gateway does not support T.38. If T.38 loose mode is active, one of the gateways in a call does not support T.38, and a compression codec is in use, the gateways must autonomously switch to G.711 without direction from the CS2K.

This feature is dependent on SN09 activity A00009294 and A00009443 for SIP/NGSS interworking.

64.3 Interworking and Scenarios

The feature covers FAX interworking between the following GWs in the Cable Solution:

- PacketCable 1.5 GW (MTA or MG)
- PacketCable 1.0 GW (MTA or MG)
- PVG (T.38 Annex D only)
- M2000 (T.38 Annex D only)
- SIP/SIPT
- IWSPM (G.711-only)

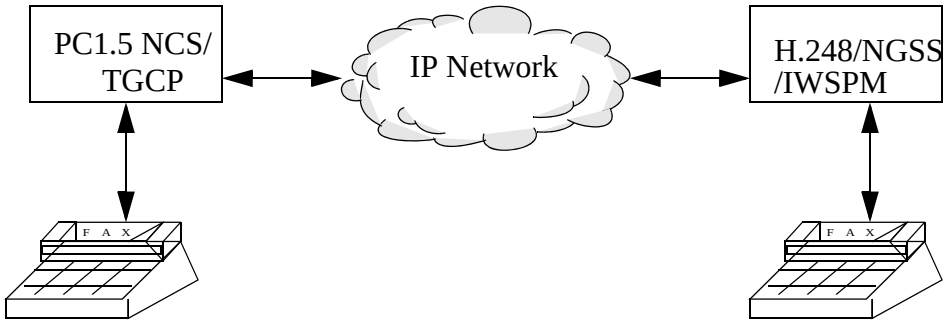
Called FAX
- ANS/CED Tone
- V.21 Preamble



Calling FAX
- CNG Tone

Called FAX
- ANS/CED Tone
- V.21 Preamble

64.4 Software Requirements or Dependencies

The feature requires the following items in place for successful T.38 functionality:

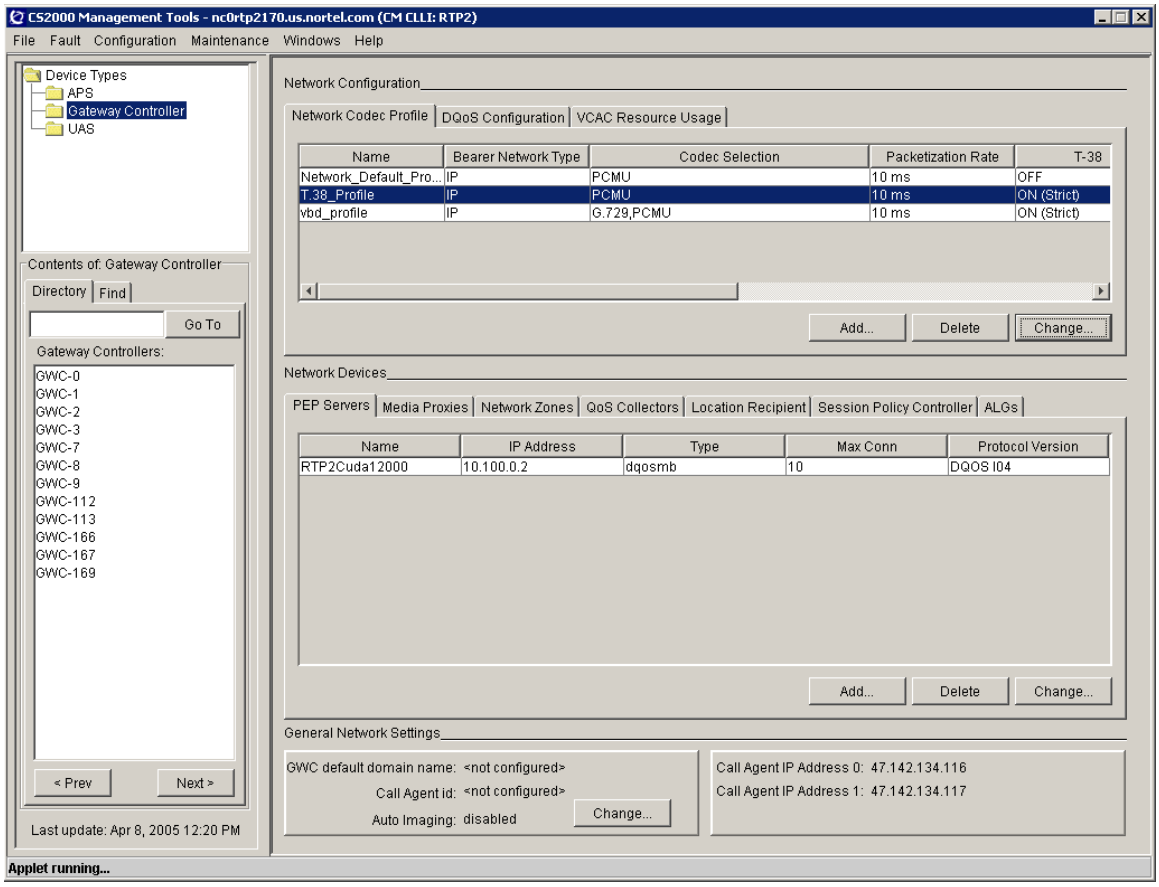
- SN09 SESM for setting up T.38 mode
- PacketCable 1.5 compliant GWs

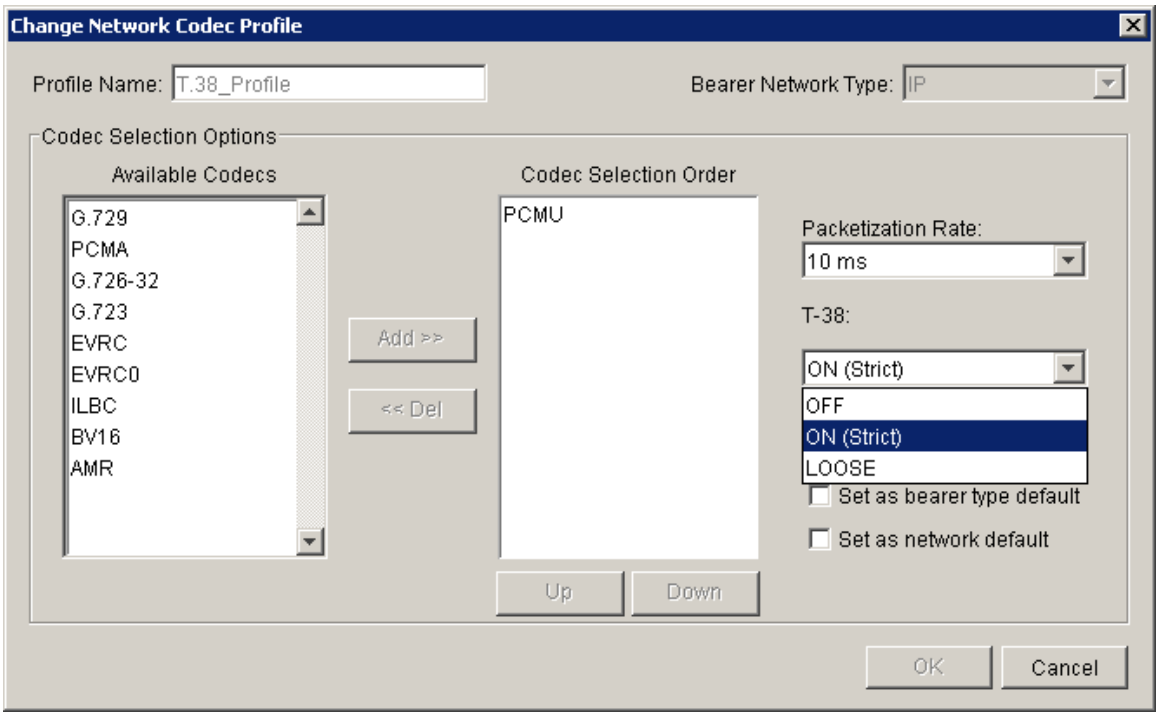
  Note: PacketCable GW's MUST advertise support for the FXR package in the Capabilities Audit response in order to use T.38.
- GWC load with all the feature related changes (including A00009294 and A00009443 content)

64.4.1 T.38 Provisioning from SESM

When adding a new network profile, the user could choose from one of three T.38 options currently provided on the CS2M GUI. The options are: “OFF, “ON (STRICT)”, and “LOOSE”. Prior to SN09 OFF was represented by disabled and ON(STRICT) was represented by enabled. The option “LOOSE” is used for packet cable. The figure below shows the T.38 options that the user may select from.

Figure one: Add network Codec Profile interface



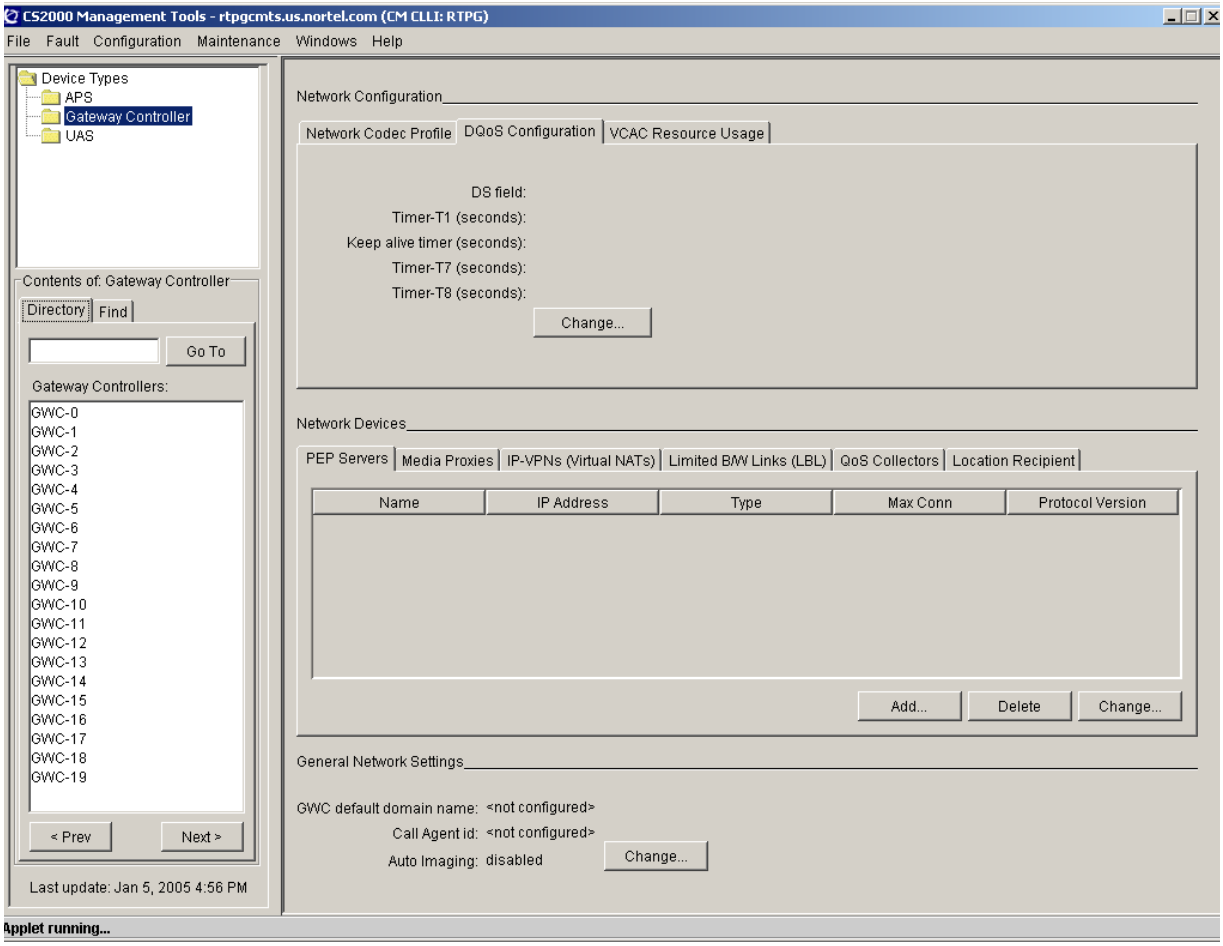


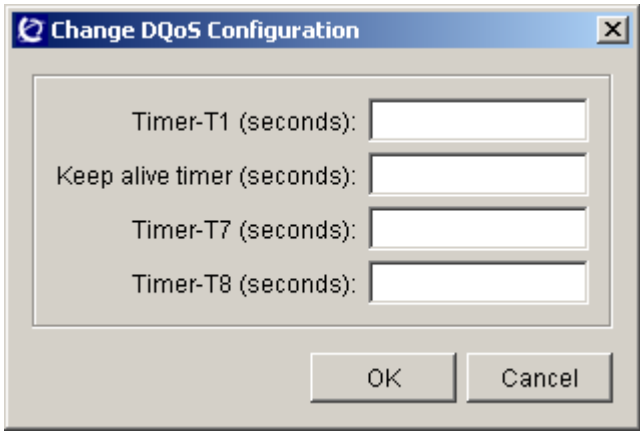
64.4.2 DSCP Provision in SESM

DS field is a fundamental value used for classification and marking of IP packets to achieve end-to-end QoS. This is a 8-bit value sent to CMTS from GWC via DQoS Signaling. This value will overwrite the TOS field in the IP header set by MTA. The media packet forwarding will then be prioritized according to the given DSCP, which is the most significant 6-bit value of the DS field. Prior to this feature, the DS field is hardcoded and set to 10111000 (184 in decimal) in SESM DQoS configuration GUI and it is displayed as “Expedited Fwding” after the user provisions the other DQoS values via “Change DQoS Configuration” dialog.

Figure 1 shows the DQoS configuration GUI display prior to this feature.

Figure 1 DQoS configuration GUI prior to this feature





Change from “DS field” to “DSCP (6-bit binary)” will be made to avoid any confusion between the 6-bit DSCP and an 8-bit DS Field value. On the “Change DQoS Configuration” dialog GUI, the “DSCP (6-bit binary)” field will be added. The pulldown menu containing predefined IP Service Class names will be provided for the selection (please refer to Table 1, “DiffServ Code Point Allocation,” on page 59). User could also input 6 binary stream. If the DSCP stream input is not one in the pulldown menu, the raw binary stream will be displayed.

111 110	--	UASS
111 111	--	EXP/LU

This function has no impact to GWC because the DSCP value is converted to DS field (8-bit) by left-shift 2. This guarantees that bit 6 and 7 are set to zero.

64.5 Limitations and restrictions

In order to interworking with NGSS/SIP or SIPT, the NGSS software containing A00009443 content needs in place so that T.38 can be set properly. And for interworking with H.248 PVG, A00009294 GWC-related content is also required.

This feature will not support T.38 interworking with Gateways not included in the Cable Solution. This includes (but is not limited to) H.323 gateways, MGCP gateways, and other H.248-based gateways such as MG9K.

A PVG with a VSP3 card is required for T.38 interworking with PacketCable devices.

This feature will NOT support T.38 interworking with the IWSPM. G.711 will be used for all FAX calls involving the IWSPM.

This feature will only perform T.38 integration testing with Gateway vendors that can provide a T.38-capable load during the design phase of this feature. At the time of this FN, this only includes the Arris TTM. Currently, Motorola MTAs and Nuera Media Gateways are not planned for integration testing.

This feature will not make use of the fax tone "ft" or modem tone "mt" events in NCS or TGCP.

There is no impact to PacketCable Event Messaging due to T.38 behavior, with the exception of Electronic Surveillance. This feature will not support PacketCable 1.5 Electronic Surveillance, since there is other work required beyond the scope of this feature for full PC 1.5 ES compliance.
If the customer chooses to interwork with a Gateway (or SIP Client on the far end of a SIP trunk) that supports neither G.711 nor T.38, FAX calls will fail regardless of whether strict or loose mode is active.

T.38 functionality will not be supported for TGCP PTS trunks.

T.38 Annex D functionality is not supported between VRDN-based SIP Trunks and H.248 gateways (e.g. PVG). Therefore, if a PacketCable MTA/MG originates a call through a VRDN SIP trunk, terminating to a PVG, FAX calls will not be successful. This scenario will work with NGSS SIP trunks configured for T.38 support. Also, PacketCable MTA/MG to VRDN SIP to PacketCable MTA/MG calls will be supported using T.38.

64.6 Interactions

Not Identified.

64.7 Glossary

Term	Description
CS2K	Call Server 2000
CMTS	Cable Modem Termination System
MTA	Multimedia Terminal Adapter
GWC	Gateway Controller
MGC	Media Gateway Controller - refers to GWC/CS2K for trunks
PVG	Passport Packet Voice Gateway (Passport15000)
SDP	Session Description Protocol (IETF RFC 3266)
G3FE	Group 3 Facsimile Equipment G3FE refers to any entity which presents a communication interface conforming to ITU- T Recommendation T. 30, T. 4, and optionally T. 6. A G3FE may be a traditional G3 facsimile machine, an application with a T. 30 protocol engine or any other possibility mention in the network model for IP Facsimile mentioned in Recommendation T. 38.
SIP	Session Initiation Protocol (IETF RFC 3261)
SIP-T	Session Initiation Protocol - Telephony ITU-T based standard, that encapsulates ISUP messaging as payload within SIP messages.
UDP	User Datagram Protocol (IETF RFC 768)
UDPTL	Facsimile UDP Transport Layer protocol (ITU T.38)
CED	Called terminal identification answer tone of Fax device (2100 +/- 15 Hz, continuous tone, duration 2.6-4.0 sec.) see T.30 chapter 4.1

65: Functional description (FN): A00009353

65.1 Feature name and Feature ID

A00009353 GWCUnit Availability/ Health Monitoring

65.2 Description

This feature addresses the prevention of GWC node outage caused by an improper SWACT to a GWC unit which appeared to be in good condition but was not.

This feature enhances the existing PreSwact audits and also create a new framework to monitor the health condition of the application resources like TAPI resource objects and Acceptor queues.

This feature will address the following:

1. Enhancement of the existing PreSwact audit.

2. Introduce a new alarm which will be raised whenever PreSwact audit fail.

65.2.1 Enhancement of the Existing PreSwact audit

Currently the PreSwact audit performs a set of checks to estimate the health of the inactive unit. This feature enhances the checks to consider additional fault conditions, such as

1. Datasync mismatch with the SESM
2. Invalid/Mismatch in some of GWC flash and GWC RAM data.
3. Application resource issues such as TAPI blocks (Transaction, Request and call)
4. Messaging resources (Acceptor queue on TAPI and Connection Broker).
5. Patching in progress in the inactive unit.However no alarm will be raised if the preSwact audit fails under this condition.

The PreSwact audit runs at a frequency of 40 seconds and with priority 6.

Swact force can still be used to force a manual warmswact when the preSwact audit fails and alarm raised.This existing functionality will not be changed.

65.2.2 New PreSwact alarm

This feature will introduce a new alarm which will be raised when ever PreSwact audit fails. An alarm will be raised with proper text which explains which component has led Preswact audit to fail. The PreSwact runs

periodically and raises alarm for PSA fail on error conditions.The specific problem displayed at the GWC level for the alarm raised will match with the swact failure reason at the SESM GUI.

65.2.2.1 Details of alarm

The details of the new alarm are as foll

Table 4: PreSwact Alarm details

Description	PreSwact Audit Failure
Severity or Level	Major
Category	QualityOfService
Probable Cause	resourceAtOrNearingCapacity
Component	NODEMTC
Specific Problem	Description about the component which caused the PreSwact audit failure.

66: Functional description (FN): A00009359

66.1 Feature name and Feature ID

A00009359 HW Intro of MCPN905 for Compact Call Agent

66.2 Description

66.2.1 Overview

This feature introduces the MCPN905-270 card for the Compact Call Agent application. The MCPN905 is being introduced to reduce recovery times on restarts as well as to increase overall capacity of the Compact Call Agent. It is expected the performance gain will be in the order of 1.6-1.7x faster than the MPCN765 card.

The MPCN765 card continues to be supported.

The MCPN905 is the next generation high performance hot swap CompactPCI Peripheral slot CPU board. It includes a new memory controller (MV64360) which is functionally equivalent to PMC280. .

As there is no persistent memory on the MCPN905 board, an 815 PrPMC has been added to the MPCN905 to add persistent memory. Each process running on the 905 that uses persistent memory accesses the memory on the 815 through the PCI bus.

66.2.2 Configuration

The MCPN905 card for the Compact Call Agent application is configured with the following:

- 815 PMC used for persistent memory
- Fiber Channel PMC used for Call Agent Sync
- 2.0 GB Memory

This configuration has been assigned the PEC code NTRX51HZ

A new transition module for the rear slot has the PEC code NTRX51HS.

66.2.3 Performance

The MCPN905 card for the Compact Call Agent application is being introduced for enhanced performance, specifically, call capacity and restart times.

Call Capacity: The expected performance gain is of the order of 1.6-1.7 x over the MPCN765 card. The committed BHCA capacity will be available at the First Customer Ship (FCS) timeframe.

Restart Times: Warm Restart times on the MCPN905 card will be less than 30 seconds. (It is expected that they will be less than 20 secs - to be confirmed).

66.2.4 Load naming convention

Due to differences between the MCPN765 and MCPN905, the ncgl cca loads are not binary compatible; a new platform load is introduced for the MCPN905 card. The load name is of the form:

- ncgl_cca_905_image_8.ww.rr.pp

In order to more clearly identify the loads, the load name for the MCPN765 card has been modified from the form:

- ncgl_cca_image_8.ww.rr.pp

to:

- ncgl_cca_765_image_8.ww.rr.pp

At the ccamtc map, sys level, the QryLD command shows the new loadnames, including the appropriate 765 or 905 indicator.

66.2.5 Load Delivery

For load delivery, the 905 cca load has been added to the existing RPM file

ncgl_cca_mc_images-8.ww-rr.pp.noarch.rpm

When the **platform_load_install.sh** script is used to install the RPM file, the mc and both 765 and 905 cca images are installed in the /swd/3pc directory on the bootp server.

66.2.6 Configuration of the 905 CCA card in the SAM21 EM GUI

Detection of the MCPN905-270 card version is done automatically in the EM when the card is inserted in the slot. After the card type is detected, the installer assigns the Call Agent service type.

On the Equip tab, the Card Type is shown as MCPN905, with a memory size of 2048.

The configuration data supplied at commissioning time is identical for the MCPN765 and MCPN905 cards with the exception of the load name. It is ncecessary to supply the correct 765 or 905 specific load name when setting the boot load name on the provisioning panel. Additionally, the Firmware version will appear different.

66.2.7 H/W Upgrades

In service upgrades of an office from an MCPN765 card to MCPN905 card is supported. The procedure uses the Norestartswact capability of the core to minimize the impact of the upgrade.

At a high level, the procedure is as follows:

- Drop Sync. Remove inactive CA card and transition module.
- Insert and commission new CA card and transition module. Run diagnostics.
- Boot new card (inactive). Soak.
- Perform onp/norestartswact procedure to switch activity to new card. Soak.
- Remove old CA card and transition module.
- Insert and commission new CA card and transition module. Run diagnostics.
- Boot new card. Soak.
- Sync.

Abort procedure is also provided .

This procedure is provided via Installation Method (IM).

66.3 Hardware Requirements or Dependencies

- MCPN905-270 card configured as above (PEC NTRX51HZ)

- MCPN905 compatible transition module (TM) (for rear slot) (PEC NTRX51HS)

66.4 Software Requirements or Dependencies

- NCGL_8 905 CCA load
- SN09 Shelf Controller and SAM21 Manager loads (including support for MCPN905 card)
- SN09 SOS (Callp Application) load

66.5 Limitations and restrictions

- Fiber Channel continues to be supported for sparing in SN09.
- For this release, the maximum amount of memory available for SOS (Callp Application) is the same as on the MCPN765 card.
- The MCPN765 and MCPN905 card versions cannot be mixed or synced except during the MCPN765 to MCPN905 upgrade procedure.
- An additional GigE port is available on the transition module, but is not used in this release.

66.6 Interactions

None.

66.7 Glossary

Term	Description
SC	Shelf Controller
CCA	Compact Call Agent
MC	Message Controller

67: Functional description (FN): A00009361

67.1 Feature name and Feature ID

A00009361 - CICM: Enhancement to IP Phone 2001 CICM client

67.2 Description

The IP Phone 2001 was introduced into the CICM portfolio of terminals in the SN07 CICM release in activity A00003951. The IP Phone 2001 was designed as a low cost alternative to the 2002 and 2004 terminals and with this cost reduction the IP Phone 2001 was designed without any feature keys.

The CICM supports the Centrex features and directory contacts by using the dedicated feature keys found on the IP Phone 2002 and 2004, however, with the 2001 not actually having any feature keys the approach was taken to provide a limited set of features using the 'Services Key' as a form of feature activation. The core provides the ability for terminals that do not support 'flash hooks' to use the 3WC or CXR features to trigger other features via * access codes. If 3wc/cxr was provisioned on the line that the 2001 terminal was connected to, the user could hit the 'services key' to perform a flash hook and dial the access code for the required feature.

The limitations in this approach meant that some of the features were not supported (a core restriction with using 3wc/cxr) and the user visible indications of the current state of the feature were not present, for example on the 2004 with Call Forward active you would have an icon next to the feature key showing its status, on the 2001 no sure indication was presented. This made the general ease of use not to the standard expected of an IP client.

The purpose of this feature is to provide a more manageable approach to feature interactions in the 2001 and emulations, such as the 2033.

67.3 Centrex Features on the IP Phone 2001 and emulations.

The real estate on the 2001 is limited and thus it is a challenge to provide the feature activation functionality that would put it on a par with the 2002 or 2004 terminals.

In previous terminal development on the CICM, an approach was adopted to limit the use of the soft keys. This was mainly driven by the lack of characters that can be assigned to a soft key and with CICM providing UI's for a number of nationalities this became an issue with regards to languages. The approach to limit the soft keys to just a small selection of Keywords (OK, Cancel, Menu, Yes, No, etc) was adopted. This leaves a number of the soft keys empty in a normal menu or call scenario.

On the IP Phone 200x, during idle state (and not active in a menu) only the far left hand soft key is used. This displays the option 'Menu' and provides the user with access to all the menus available.

For the IP Phone 2001 these soft keys will be used as feature keys, acting in the same manner as the features keys provided on the 2002/2004.

Feature Activation will also be made available to the user from an extra menu option,' Call Services' which has added to the main menu.

KEM features provisioned on the user's line will not be accessible to the 2001.

67.4 Assigning Features to Keys

Any features provisioned on the Users line will be made available to the user when they are logged into an IP Phone 2001 terminal. Two methods are available to the user for how these keys are assigned.

The first time a user logs into the IP Phone 2001, the softkeys will be automatically provisioned for them. The method for this provisioning is based on the numerical order of the feature keys on the core.

So for example if a user transfers from a 2004 to a 2001 for the first time, the features that the user has provisioned on features keys 2, 3 and 4 will be assigned to softkeys 2, 3 and 4.

Depending on the feature profile, more features may be automatically provisioned for the user. The following table provides an example of what the user may have provisioned and what they might expect when they log into the 2001 for the first time.

Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key	Automatically provisioned on a IP Phone 2001
1	Three Way Call	Hide when Idle	1	Yes, Only displayed when the terminal is not idle.
2	Call Forward	Hide when Active	1	Yes, Only displayed when Terminal is Idle
3	Make Set Busy	Hide when Active	2	Yes, Only displayed when Terminal is Idle
4	Busy Override	Hide when Idle	2	Yes, Only displayed when the terminal is not idle.
5	Ring Again	Never Hide	3	Yes, This is displayed in both idle and no idle states
6	Call Waiting	Never Hide	NONE	All three soft keys are now allocated; this feature is not automatically provisioned.

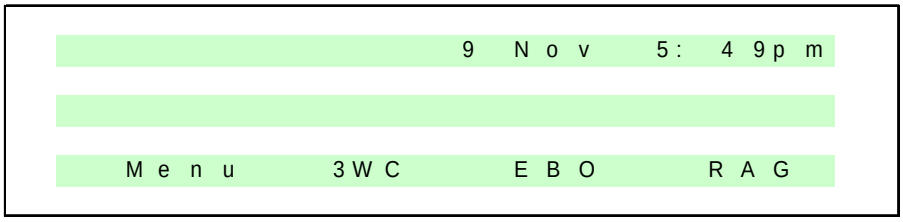
If all the feature profiles were set to never, only features assigned to keys 1, 2 and 3 would be automatically provisioned.

From the automatic provisioning described above the user does not have a dedicated key for Call Waiting. If the user feels that they use the feature more than one of the features that has been automatically provisioned then they can change the feature assignment manually on the terminal itself.

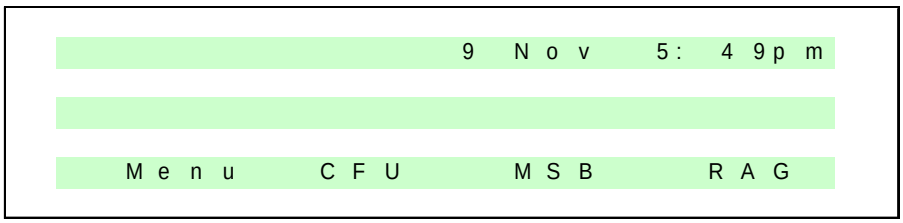
The new ‘Call Services’ menu will present the entire list of features that the user has assigned. From here they can either activate a feature by selecting it from the menu, or reassign it to one of the soft keys, this provides an interface suitable to them.

Using the example above, if the user wishes to allocate Call waiting to soft key 3, because they feel they use that feature more than Ring Again, then they may do so. If they wished to allocate Call waiting to key 1 then they will be replacing both 3WC and Call Forward, this is because the Call Waiting feature profile is set to never hide and is displayed when idle and non idle.

The following is an example of how the terminal will look based on the automatically configured softkeys from the users line configuration previously mentioned.



When a terminal transitions to an idle state, the ‘display when idle’ features will be available.

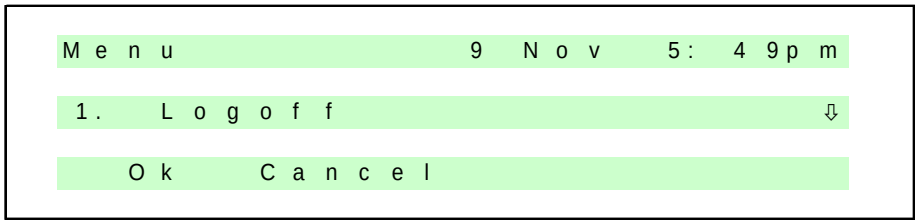


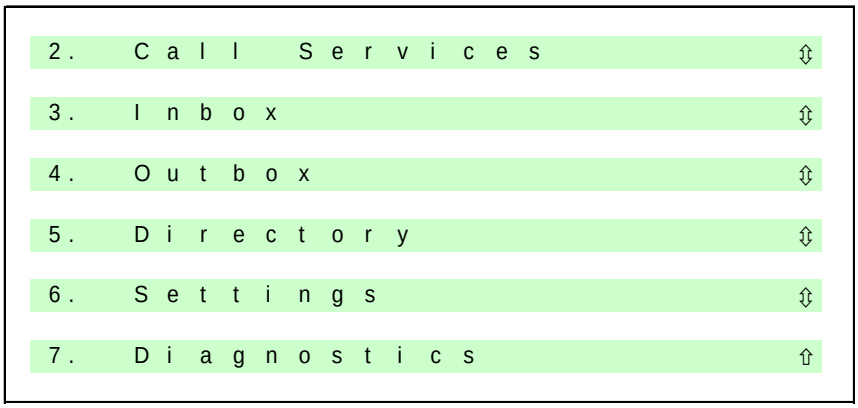
When assigning features the user will be prompted for confirmation, this confirmation will also display any features that will be unassigned from the soft key.

All this mapping will be transparent to the user, so when they log back into a 2004 terminal the keys will be displayed in their original assignment. Any subsequent times that the user logs into the 2001 will present the keys in the format that the user last used them. Only on the first time that the user connects to a 2001 will the automatic allocation occur.

67.5 Menu Map

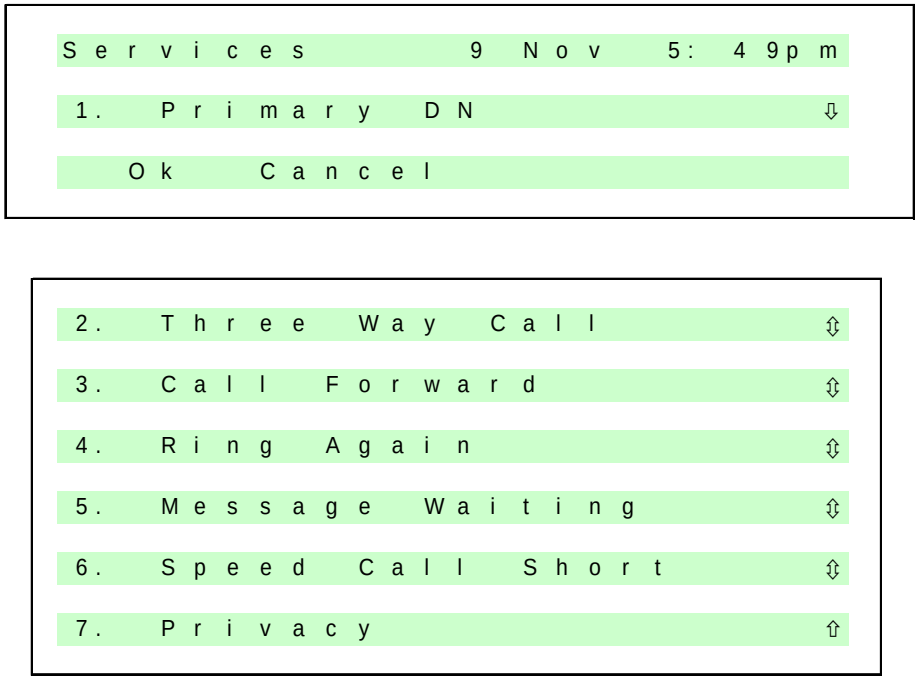
The following screen representations show what will be presented to the user when logging on to a gateway, and navigating the feature allocation menus of the i2001





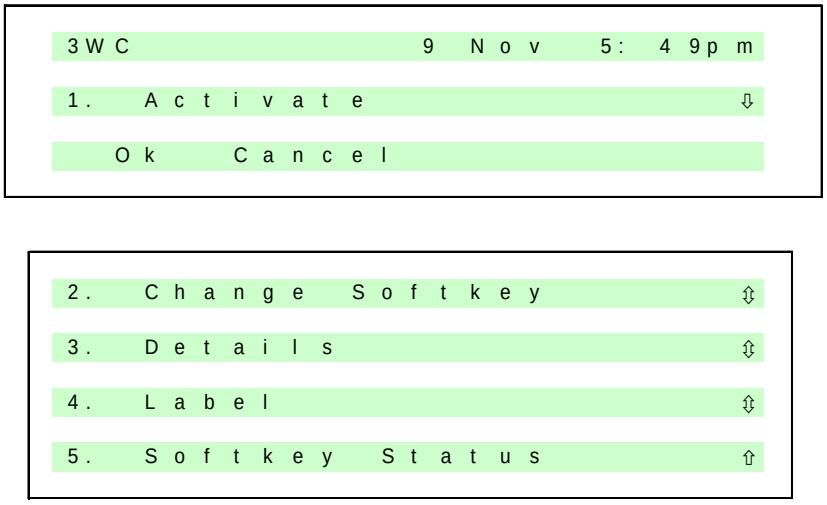
67.5.1 Call Services Menu:

Presents a list of the Features assigned on the user's line, this user has 7 features assigned; this is in the order in which they would be displayed on a 2004/2002 terminal.

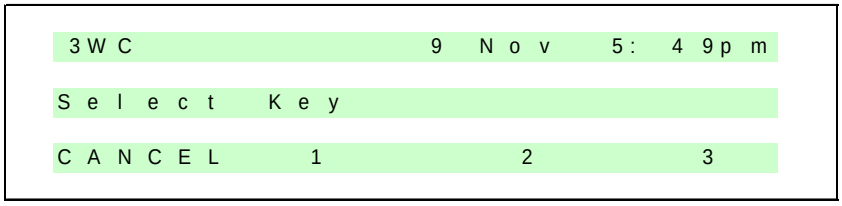


67.5.2 Assign / Activate Menu:

When Highlighting a feature from the list and selecting OK the user will be presented with a further menu. From here they can manually activate the feature or assign it to one of the soft keys.

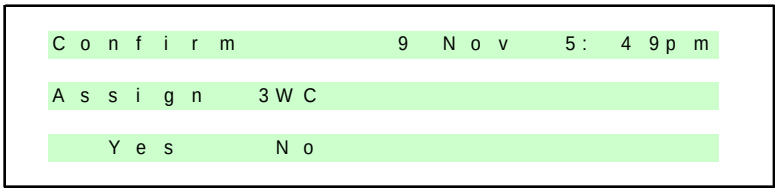


When assigning a feature to a soft key the user will be presented with the following screen.

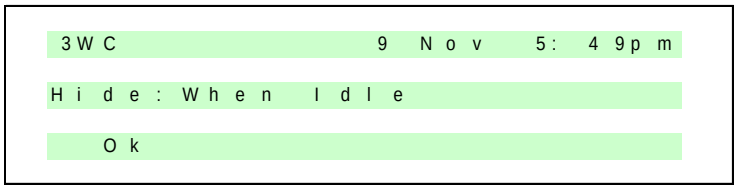


The user would then press the key that they wish to assign the feature to and a confirmation screen will be presented to the user.

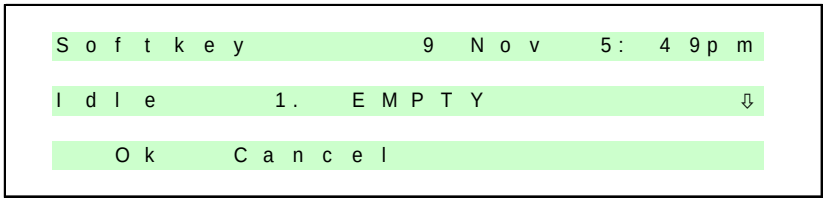
In the following example we are assigning three way call to soft key 1, when no features are currently assigned. So the user is just prompted with a confirm message.

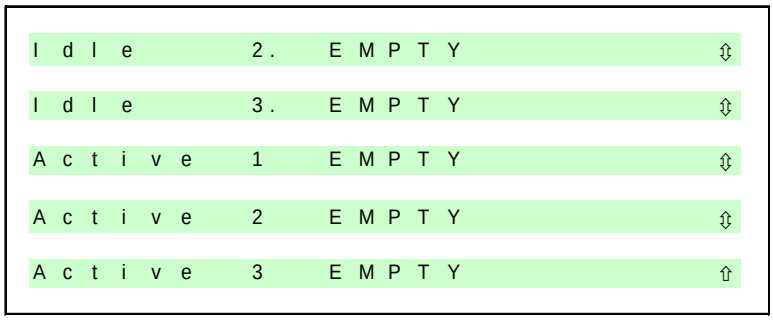


When selecting the Details option, the details of the feature are displayed to the user.

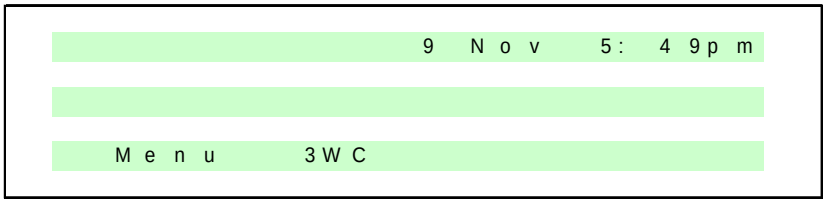


When selecting the Soft key Status, the following will be displayed.





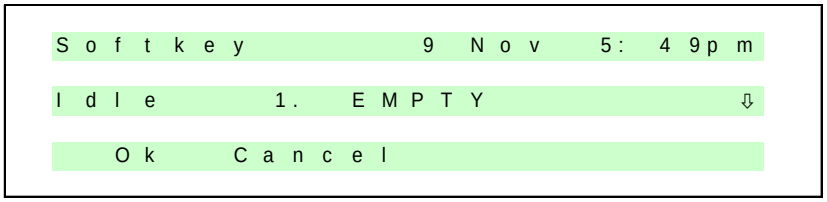
The list of currently assigned features is Empty. The user selecting ‘Yes’ to the assignment would result in 3WC being assigned to soft key 1 when the terminal is not idle

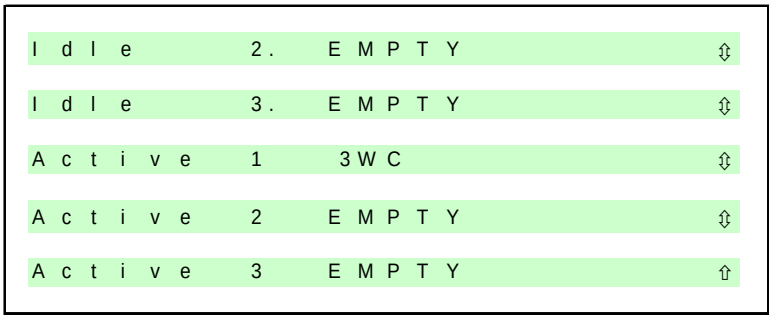


The users feature assignment would then look like this.

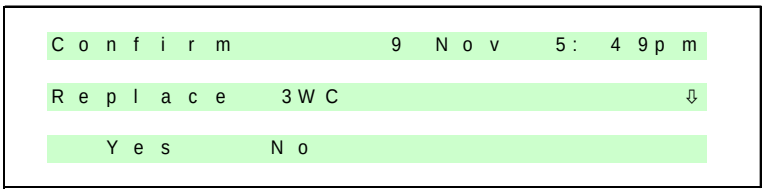
Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key
1	Three Way Call	Hide when Idle	1
2	Call Forward	Hide when Active	None
3	Make Set Busy	Hide when Active	None
4	Busy Override	Hide when Idle	None
5	Ring Again	Never Hide	None
6	Call Waiting	Hide when idle	None

The soft key status page would now resemble.





If the user decides to replace 3WC with Call Waiting (Hide when idle) the confirmation would include the 3WC feature in the list of Currently Assigned features.

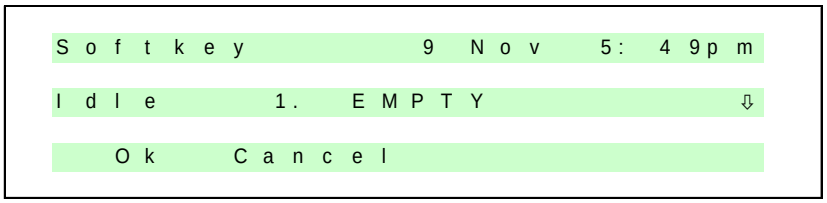


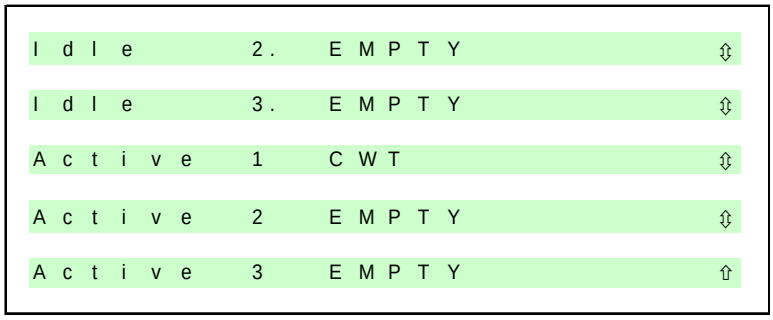
The users feature assignment would then look like this.

Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key
1	Three Way Call	Hide when Idle	None
2	Call Forward	Hide when Active	None
3	Make Set Busy	Hide when Active	None
4	Busy Override	Hide when Idle	None
5	Ring Again	Never Hide	None

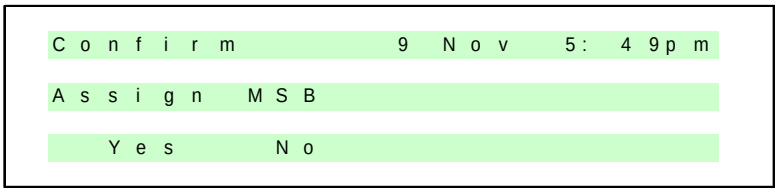
6	Call Waiting	Hide When Idle	1

The soft key status page would now resemble.

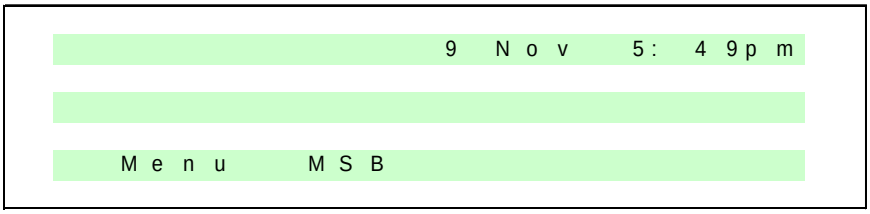




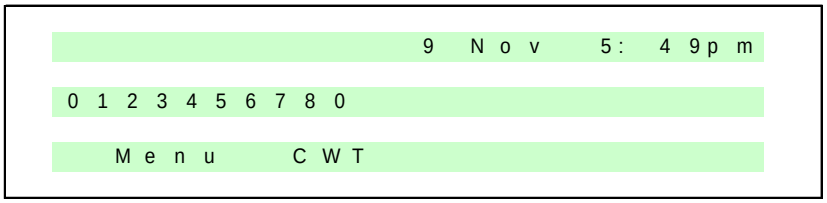
The user then wishes to assign Make Set Busy to Key 1 as well, Make Set Busy is configured as a Hide when DN is not idle feature, so it can be assigned to Key 1 without effecting any features already configured (only Call Waiting is assigned and because it is hidden when the feature is idle, there theoretically is a key available).



The list of currently assigned features to an idle soft key 1is Empty. The user selecting ‘Yes’ here would result in MSB being assigned to soft key 1 when the terminal is idle.



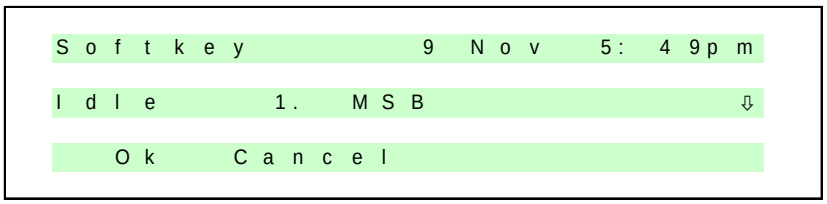
But still display Call Waiting when we are in a non idle state.

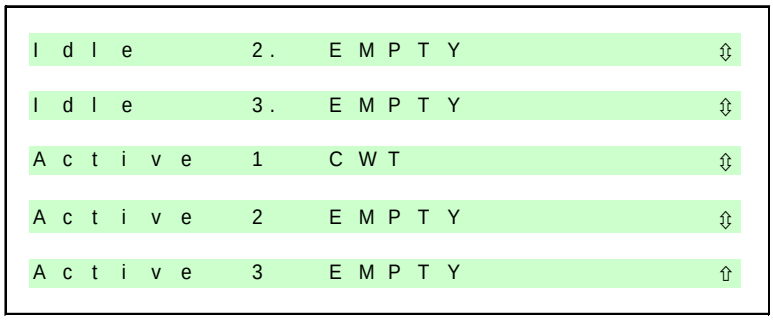


The users feature assignment would then look like this.

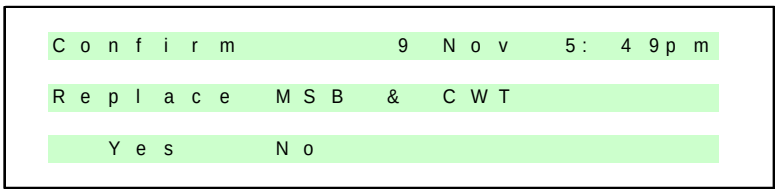
Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key
1	Three Way Call	Hide when Idle	None
2	Call Forward	Hide when Active	None
3	Make Set Busy	Hide when Active	1 (shown when idle)
4	Busy Override	Hide when Idle	None
5	Secondary DN	Never Hide	None
6	Call Waiting	Hide When Idle	1 (shown when not idle)

The soft key status page would now resemble.

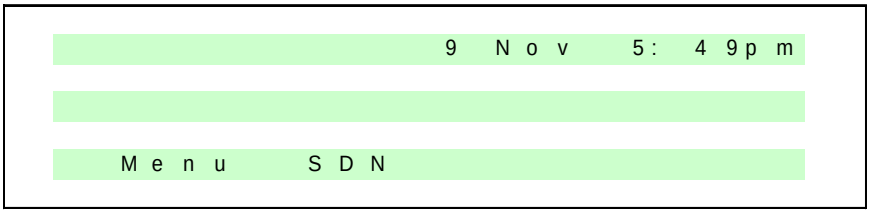




Now if the user wishes to assign a never hide feature, such as a secondary DN to soft key 1 they will be replacing Make Set Busy and Call Waiting.



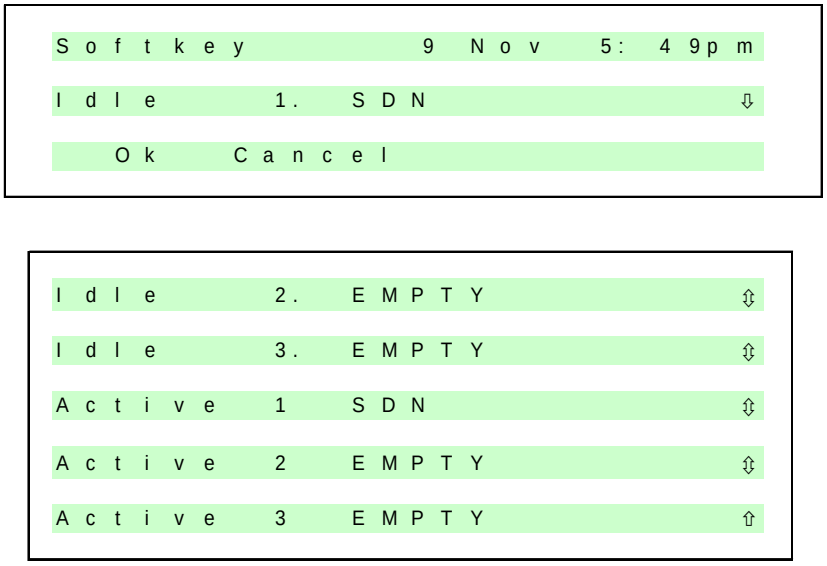
The fact that the secondary directory number feature is never to be hidden means that it will replace both the features assigned to key 1. Upon confirmation the user would see the following when idle and not idle.



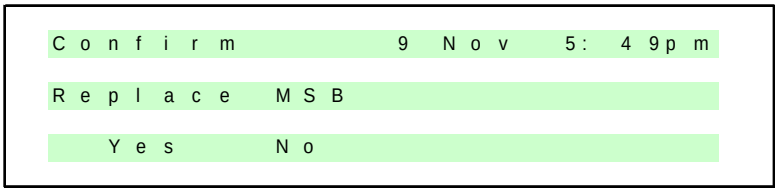
The users feature assignment would then look like this.

Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key
1	Three Way Call	Hide when Idle	None
2	Call Forward	Hide when Active	None
3	Make Set Busy	Hide when Active	None
4	Busy Override	Hide when Idle	None
5	Secondary DN	Never Hide	1 (shown in both idle and non idle states)
6	Call Waiting	Hide When Idle	None

The soft key status page would now resemble.



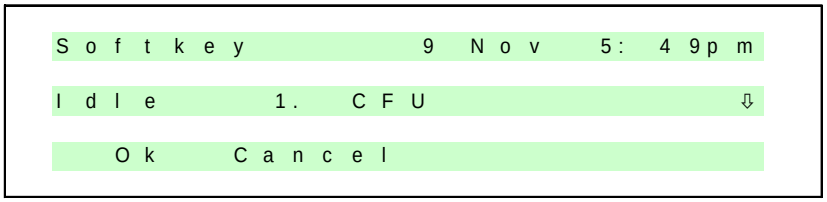
Alternatively, if the user wishes to replace MSB with another hide when not idle feature, only MSB will be replaced and not both assigned features. In this example CFU is being assigned to Key 1

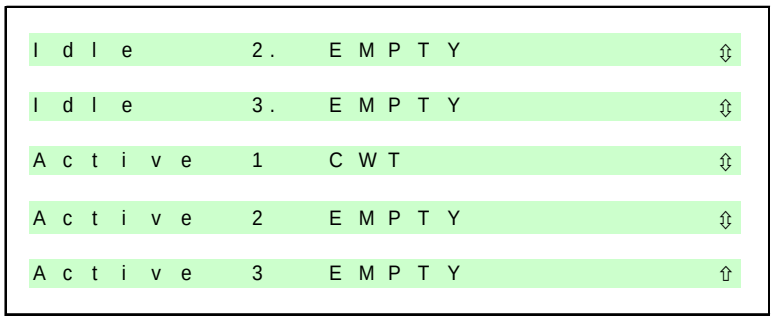


The users feature assignment would then look like this.

Key	Users features on a IP Phone 2004	Feature Profile	IP Phone 2001 Soft Key
1	Three Way Call	Hide when Idle	None
2	Call Forward	Hide when Active	1 (shown when idle)
3	Make Set Busy	Hide when Active	None
4	Busy Override	Hide when Idle	None
5	Secondary DN	Never Hide	None
6	Call Waiting	Hide When Idle	1 (shown when not idle)

The soft key status page would now resemble.



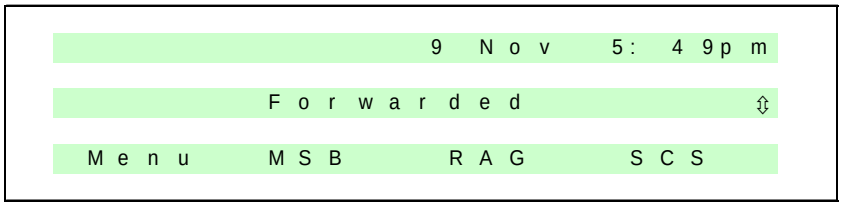


67.5.3 Feature Indication in the Call Services Menu / Terminal Display:

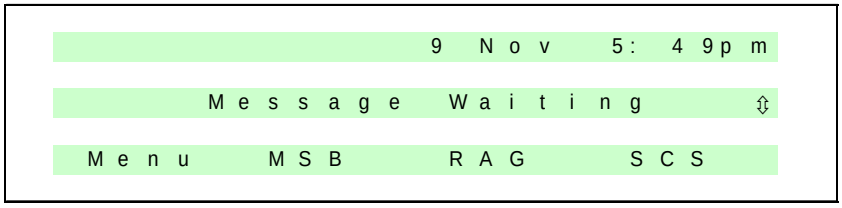
Features can also be activated via the menu system without necessarily having a dedicated softkey assigned; the status of the features will be indicated by a Message being displayed on the terminal when idle as well as an icon being placed next to the features name in the Call Services Menu

For features that are active on the terminal when the set is idle the user would use the navigational up and down arrows on the terminal to scroll through the list of features active.

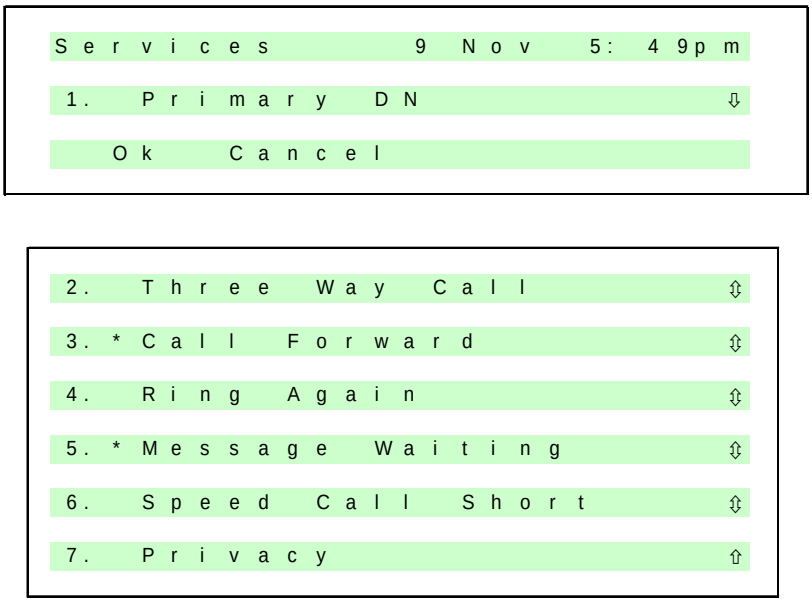
For example: This terminal has no feature keys assigned but Call Forward and Message Waiting are both active.



Then by pressing up or down on the navigational buttons it would display the next active feature in the list.



Alternatively, the Call Services Menu would also indicate their status.

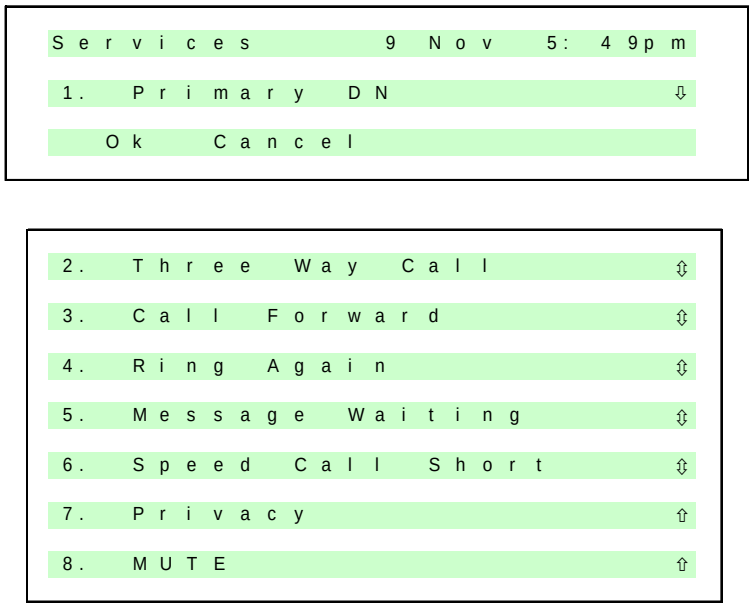


67.5.4 IP Phone 2001 MUTE functionality:

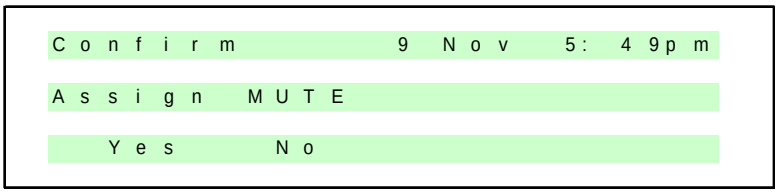
The IP Phone 2001 does not have a physical mute button, although the 2001 does not have an external microphone its necessary to provide such functionality when active in a call on the handset.

Mute is only applicable in a non idle state and can be assigned to any of the soft keys in the same manner as the Centrex features.

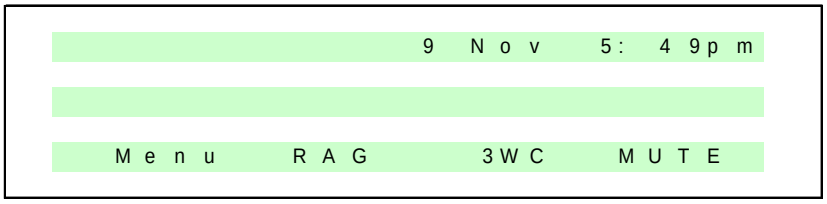
Independent of the features provisioned on the terminal the MUTE option will be displayed in the Call Services menu at the bottom of the list.



Select and assign the MUTE option in the same method as described earlier. This will occupy a Non idle soft key space, overwriting any current configuration on that key.



When assigned the MUTE button will be displayed against the relevant soft key.



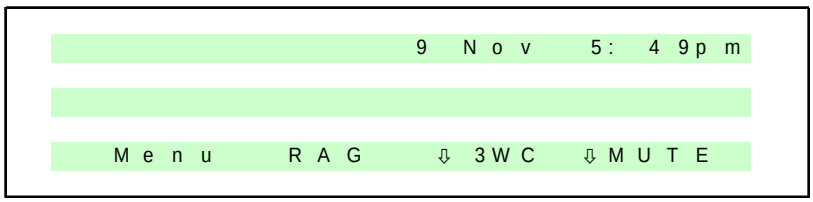
The IP Phone 2033 does actually have a physical mute button, where the majority of the functionality introduced by this feature is also applicable to the 2033, the mute option will not be displayed.

67.5.5 Indication of feature state on the Soft keys:

In the D91 phase 2 firmware stream we currently do not have the ability to perform reverse video on the softkey labels. A development activity is being discussed to provide this functionality with the firmware development team. Until the method for reverse video to be displayed on the terminals softkey is available we will be providing an alternative.

An Icon will be placed next to the Feature label on the softkey to provide a visual indication of the features state.

Currently an active feature will be represented by the following:

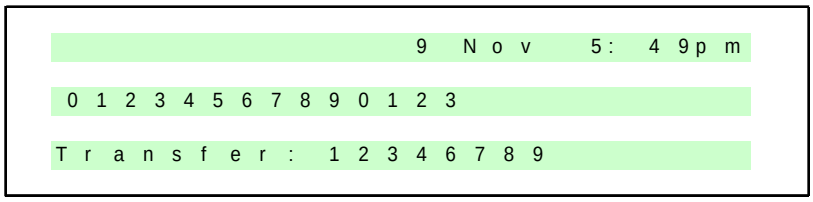


In this example the 3WC and the Mute functionality is activated. This extra icon occupies one character on the soft keys label. The result of this means that the text in the label will be moved one space to the right. When the label exceeds 4 characters and the feature is activated the label will be truncated and an ellipsis will be appended.

On the 2002 and 2004's feature keys icons are used to represent the stages that the features are in, usually by flashing the icon during provisioning. Its not possible to provide any form of flashing on the labels above the soft keys, so the tri states that features can be involved (on, off and provisioning) in is not represented The feature is either on (activated or provisioning) or off.

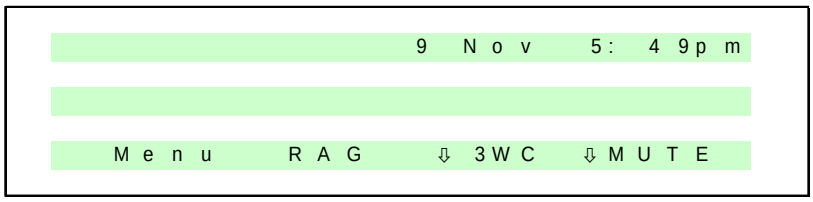
67.5.6 Displaying the soft key labels during a call:

When active on a call, the 2001 clears the two display lines and leaves the context line present. This is to enable the user to see the incoming DN, dialed digits, transfer details, etc. With these occupying the screen the soft keys are no longer visible.



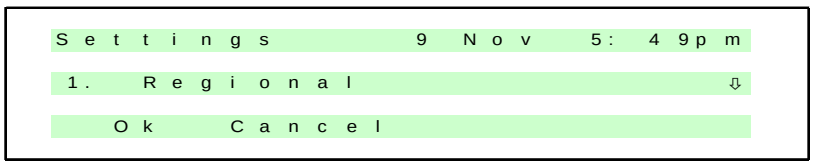
A timer is started while the labels are not visible on an incoming or outgoing call, after a set duration the labels will appear again.

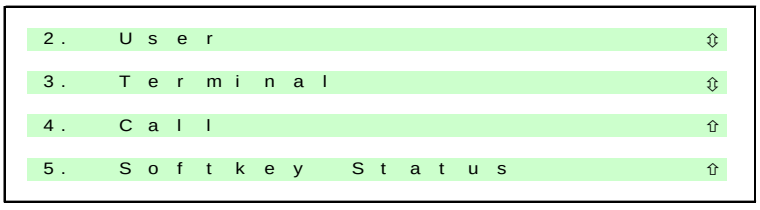
The soft key labels can be removed from the display at any time by pressing the ‘services key’. While hidden pressing the ‘services key’ will present the labels back onto the screen. The timer is not started when the user manually hides the soft key labels, only when active on a call.



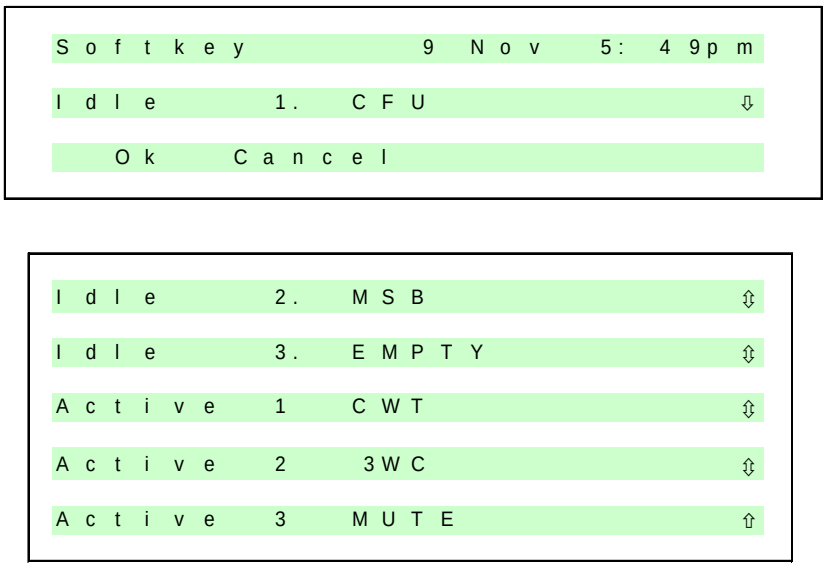
67.5.7 Displaying the configured soft keys:

The list of provisioned soft keys can be obtained by either selecting the Soft key Status while provisioning a feature or via the Settings menu located on the main menu.





Selecting option 5 will present the same information as during provisioning.



67.5.8 2033 compatibility:

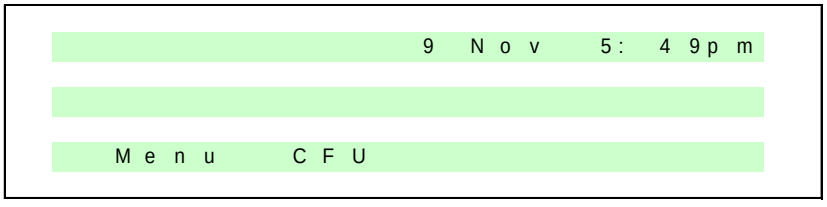
The functionality introduced by this feature is also intended for the 2033 conference phone.

Where the soft key driven functionality on the 2001 is distributed across 4 soft keys, the 2033 only has 3 but provides a ‘more’ option on the far right soft key.

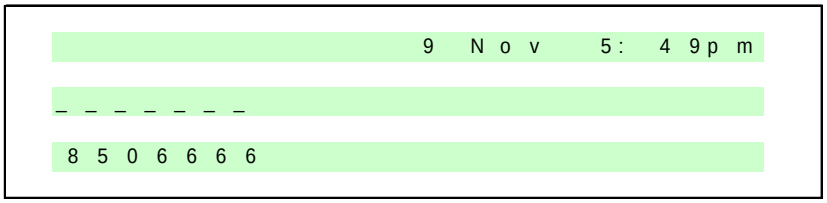
The normal display would consist of soft keys 1, 2 and more, selecting the more key will display soft keys 3, 4 and more. Selecting more this time will return to keys 1 and 2.

67.5.9 Example feature activation: Call Forward

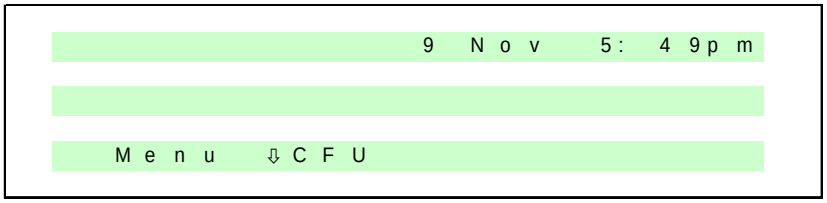
With Call Forward assign to soft key 1 and the terminal idle the user would press soft key 1.



The screen would prompt the user for the forwarding digits clearing the display of the soft keys labels. The user would enter the DN they wish to be forwarded to

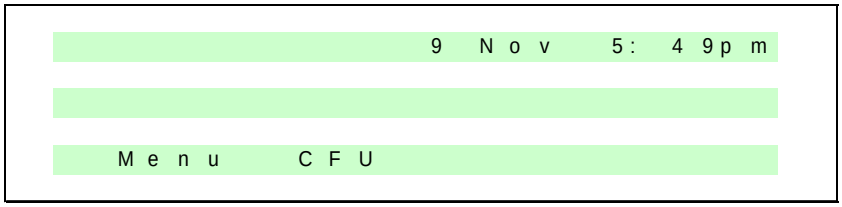


The user could then either press the service key to present the soft key labels again, or just press the soft key itself to confirm the operation.



After confirmation the terminal will place an icon next to the CFU key to indicate that its status is on.

Pressing the soft key again will return the CFU status back to off.



67.6 Feature Labels

The string interpretation for the features are available in long and short form, in Appendix A we list the features that currently have strings available on the CICM, in most cases the short form version of the feature is too long to fit in the soft keys structure. The 2001 can provide 6 characters per soft key but for aesthetics we try to use 5 for the first 3 keys and 6 for the last key, to ensure that we provide a gap between keys. The suggested soft key label will be new additions to the language strings and used as the representation for the features

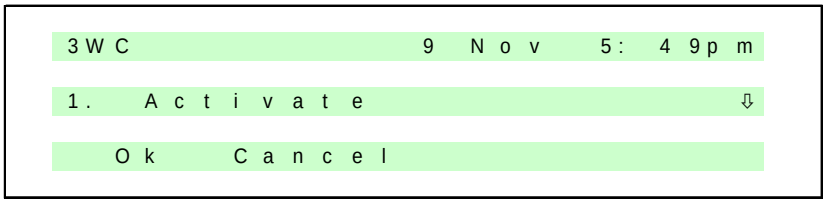
on the soft keys. Where possible the string has been limited to 5 characters but it's not possible for each feature.

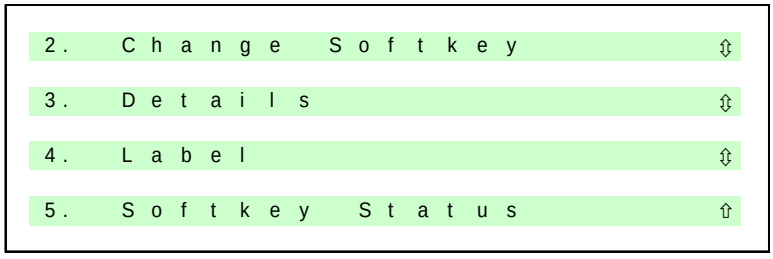
See Appendix A for details of each counties default labels.

67.7 Labeling the Softkeys

The user has the ability to re-label the soft key associated with a feature replacing the default label associated with that feature.

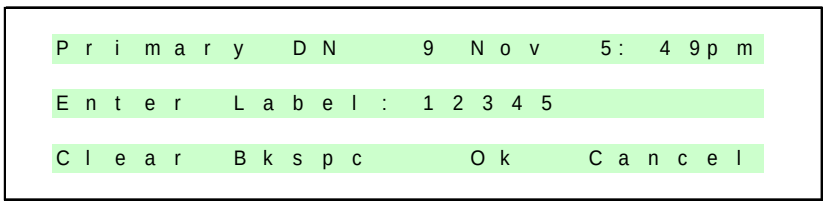
To re-label a feature the user should select the feature from the Call Services menu and select option 4 – Label.



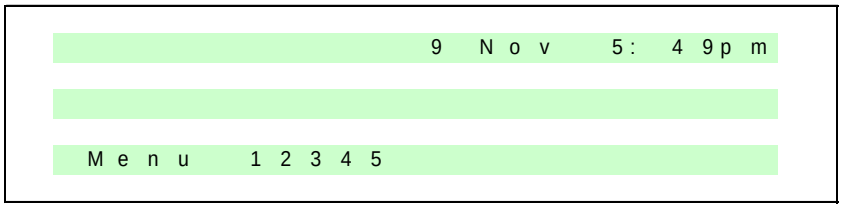


This will prompt the user to enter the label that they wish to be associated with that specific feature; all the alpha numeric characters are available including symbols.

The user is limited to entering only 5 characters.



In this example the user has assigned the numbers 12345 to their Primary DN, if the Primary DN is assigned to soft key 1 then this is how it will appear.



Use the Symbol key to enter special characters

When entering text into the soft key label the full character set is available. Each number on the key pad (except 1) has a range of symbols associated with it. Press the Symbols soft key after the keypad to obtain the special characters available.

Key 1 - Nothing

Key 2 - AÀÁÂÃÄÅÆBCÇaàáâãäåæbcç2

Key 3 - DEÈÉÊËFdeèéêëf3

Key 4 - GHIÌÍÎÏghìíîï4

Key 5 - JKLjkl5

Key 6 - MNÑOÒÓÔÕÖØmnñoòóôõöø6

Key 7 - PQRSpqrs7

Key 8 - TUÙÚÛÜVtuùúûüv8

Key 9 - WXYÝÞßZwxyýþÿz9

Key # - !"#$%&'()*+,-./0123456

67.8 Auto Labeling the Directory Numbers.

The auto propagation will not automatically assign Primary or Secondary DN's to soft keys, if the user wishes to assign a DN key to a soft key, the user should follow procedures detailed in this document.

When a DN key is assigned for the first time to a soft key, the label associated with that key will be the last 4 digits of the user DN which is configured via OSSGate.

This can then be relabeled if required by the user.

67.9 Element Manager

The Element Manager has no knowledge of a specific users soft key feature association.

67.10 Hardware Requirements or Dependencies

The IP phone 2001 is the main hardware requirement, however, for certain aspects of this feature there is a dependency on the terminals firmware. In the D91 phase 2 firmware we do not currently have the ability to Reverse Video the display above the terminals softkeys. Alternatives are presented in this FN for how we will display feature indication to the user.

Details of request to the firmware team will be documented in the Limitations and Restrictions section.

67.11 Software Requirements or Dependencies

The new firmware requirements as described earlier in the document are required.

67.12 Limitations and restrictions

The lack of the terminals firmware supporting:

- Reverse Video on soft keys.
- Context Line being used as a standard display line
- Bitmap downloading, as an alternative to using the icon or the reverse video we could send predefined bitmaps to the terminal to display. The 2001 has a fully bit mapped display but currently the Unistim protocol does not support it.
- Soft key Highlighting, as another alternative.

Configuration Limitation.

- The only supported method for provisioning LEN's and Users is via OSSGate and flow through provisioning. This ensures that all the users feature association on the CS2K and the CICM is in sync. Flow through provisioning will automatically create a label for the users DN keys and associate the correct features to keys. The Element Manager provides the ability to apply features to keys on the user’s line, but should only be used as a means to amend any inconsistencies that occurred during creation.
- No Predefined Assignments will be available; the automatic configuration will be used for the 1st time when connecting to 2001. Configuration changes will be stored and used from then on.
- The Auto configuration option is not configurable.

Possible Future Enhancements:

- Template Soft key Profiles.

67.13 Interactions

This feature has interactions with the original i2001 feature and the 2033 features from previous CICM releases,

67.14 Glossary

Term	Description
New term	definition

67.15 Appendix A: Language Strings

67.15.1 UK and US Default Soft key Labels

Feature Name	Default Softkey Label	Indication displayed when feature active and not assigned to a key.	Description
Forward	Fwd	Forwarded	Forward
Msg Wait	MsgWt	Message Waiting On	Message Waiting' short feature name
Transfer	Xfr	Call Transfer On	Call Transfer' short feature name
Ring Again	Rag	Ring Again On	Ring Again' short (and long) feature name
Speed Call	Scl	Speed Call Short On	Speed Call' short (and long) feature name
Primary DN	PDN	Primary DN On	The Most important DN. Usually assigned to feature key 1.
Time&Date	Qtd	Time and Date On	The 'Time and Date' short (and long) feature name
Agent	Agent	Agent Incalls On	Agent In calls' short feature name
DN	Dn	Directory Number On	Directory Number' short feature name
Make Busy	Busy	Busy Active	Make Set Busy' short feature name
3 Way Call	3wc	Three Way Call On	3 Way Call' short feature name
Dir. Park	DcPk	Directed Call Park On	Directed Call Park' short feature name
Not Ready	NtRdy	Agent Not Ready	Agent Not Ready' short feature name. This feature is part of the ACD family of features.
Emergency	Emerg	Emergency Active	Emergency' short (and long) feature name. This feature is part of the ACD family of features.
Supervisor	SpvIn	Supervisor Incalls On	Supervisor Incalls' short feature name. This feature is part of the ACD family of features.
Call Super	Supv	Call Supervisor On	Call Supervisor' short feature name. This feature is part of the ACD family of features.
Ans. Emerg	EmAns	Emergency Answer On	Answer Emergency' short feature name. This feature is part of the ACD family of features
Ans. Agent	AgnAns	Agent Answer Active	Answer Agent' short feature name. This feature is part of the ACD family of features.

Agent Stat	AgnSta	Agent Status On	Agent Status' short feature name. This feature is part of the ACD family of features.
Obs. Agent	AgObsv	Observe Agent On	Observe Agent' short feature name. This feature is part of the ACD family of features.
Conference	6wc	6 Party Conference	6 Party Conference' short feature name
Autodial	ADial	Automatic Dialing	Autodial' short (and long) feature name. To automatically dial the phone. Abbreviation for Automatic Dialing
Park	Park	Call Park Active	Call Park' short feature name.
Unknown	Unknwn	Unknown Feature On	This catch all feature is used when a feature is present on the feature key, but does not have its own assigned entry in this list.
Fast Xfer	Fxr	Fast Transfer On	Fast Transfer' short feature name.
Pickup	Cpu	Call Pickup Active	Call Pickup' short feature name.
Intercom	Icom	Intercom Active	Intercom (Business sets)' short (and long) feature name.
Call Wait.	Wait	Call Waiting	Call Waiting' short feature name
QryBusyStn	QBS	Query Busy Station On	Query Busy Station' short feature name.
AgtSummary	DASK	Display Agent Summary	Display Agent Summary' short feature name. This feature is part of the ACD family of features to display the summary of an agent's activities.
Q Status	DQS	Display Queue Status	Display Queue Status' short feature name. This feature is part of the ACD family of features and is used to display the status of the ACD queue.
QThreshold	DQT	Display Queue Threshold	Display Queue Threshold' short feature name. This feature is part of the ACD family of features and is used to display the threshold of the ACD queue.
FrcAgAvail	FAA	Force Availability On	Force Agent Availability' short feature name. This feature is part of the ACD family of features and is used by the supervisor to force the agent into becoming available.
Ctrl IFlow	Cif	Controlled Interflow	Controlled Interflow' short feature name. This feature is part of the ACD family of features.
SupNgtServ	NgtSrv	Night Service On	Supervisor Control of Night Service' short feature name. This feature is part of the ACD family of features.
Line Bus	Lob	Line of Business	Line of Business' short feature name. This feature is part of the ACD family of features.
Call Agent	Cag	Call Agent Active	Call Agent' short (and long) feature name. This feature is part of the ACD family of features.
Call Force	Force	Call Force Active	Call Agent with Call Forcing option. This feature is part of the ACD family of features.

67.18 Portuguese Default Soft key Labels

Feature Name	Default Softkey Label	Indication displayed when feature active and not assigned to a key.	Description
Forward	Fwd	Direccionado	Forward
Msg Wait	MsgWt	Mensagem em Espera	Message Waiting' short feature name
Transfer	Xfr	Transf. de Chamada ON	Call Transfer' short feature name
Ring Again	Rag	Toque Repetido ON	Ring Again' short (and long) feature name
Speed Call	Scl	Chamada rápida ON	Speed Call' short (and long) feature name
Primary DN	PDN	DN primário ON	The Most important DN. Usually assigned to feature key 1.
Time&Date	Qtd	Data e Hora ON	The 'Time and Date' short (and long) feature name
Agent	Agent	Chamadas de Agent ON	Agent In calls' short feature name
DN	Dn	Lista telefonica ON	Directory Number' short feature name
Make Busy	Busy	Ocupado activado	Make Set Busy' short feature name
3 Way Call	3wc	Chamada 3 vias ON	3 Way Call' short feature name
Dir. Park	DcPk	Parqueamento chamada ON	Directed Call Park' short feature name
Not Ready	NtRdy	Agente não disponível	Agent Not Ready' short feature name. This feature is part of the ACD family of features.
Emergency	Emerg	Emergência activada	Emergency' short (and long) feature name. This feature is part of the ACD family of features.
Supervisor	SpvIn	Chmd. do supervisor ON	Supervisor Incalls' short feature name. This feature is part of the ACD family of features.
Call Super	Supv	Chamar supervisor ON	Call Supervisor' short feature name. This feature is part of the ACD family of features.
Ans. Emerg	EmAns	Atender emergencia ON	Answer Emergency' short feature name. This feature is part of the ACD family of features
Ans. Agent	AgnAns	Atender Agente activo	Answer Agent' short feature name. This feature is part of the ACD family of features.
Agent Stat	AgnSta	Estado do Agente ON	Agent Status' short feature name. This feature is part of the ACD family of features.
Obs. Agent	AgObsv	Observar Agente ON	Observe Agent' short feature name. This feature is part of the ACD family of features.
Conference	6wc	Conferencia a 6	6 Party Conference' short feature name
Autodial	ADial	Marcação automática	Autodial' short (and long) feature name. To automatically dial the phone. Abbreviation for Automatic Dialing
Park	Park	Parqu. de chmds activo	Call Park' short feature name.
Unknown	Unknwn	Função desconhecida ON	This catch all feature is used when a feature is present on the feature key, but does not have its own assigned entry in this list.
Fast Xfer	Fxr	Transf. Rápida ON	Fast Transfer' short feature name.
Pickup	Cpu	Atender chamada activa	Call Pickup' short feature name.

Intercom	Icom	Intercom Activa	Intercom (Business sets)' short (and long) feature name.
Call Wait.	Wait	Chamada em espera	Call Waiting' short feature name
QryBusyStn	QBS	Questionar Est.Ocup. ON	Query Busy Station' short feature name.
AgtSummary	DASK	Mostrar Estado do Agent	Display Agent Summary' short feature name. This feature is part of the ACD family of features to display the summary of an agent's activities.
Q Status	DQS	Mostrar estado Fila	Display Queue Status' short feature name. This feature is part of the ACD family of features and is used to display the status of the ACD queue.
QThreshold	DQT	Mostrar Limite da Fila	Display Queue Threshold' short feature name. This feature is part of the ACD family of features and is used to display the threshold of the ACD queue.
FrcAgAvail	FAA	Forçar disponibil. ON	Force Agent Availability' short feature name. This feature is part of the ACD family of features and is used by the supervisor to force the agent into becoming available.
Ctrl IFlow	Cif	Fluxo controlado	Controlled Interflow' short feature name. This feature is part of the ACD family of features.
SupNgtServ	NgtSrv	Serviço nocturno ON	Supervisor Control of Night Service' short feature name. This feature is part of the ACD family of features.
Line Bus	Lob	Linha de negócio	Line of Business' short feature name. This feature is part of the ACD family of features.
Call Agent	Cag	Chmd de agente Activa	Call Agent' short (and long) feature name. This feature is part of the ACD family of features.
Call Force	Force	Chmd forçada activa	Call Agent with Call Forcing option. This feature is part of the ACD family of features.

68: Functional Description (FN) A00009362

68.1 Feature name and Feature ID

A00009362: IP Phone 2007 User Interface support

68.2 Scope

This document covers the functional description for the work required to support the IP Phone 2007 Internet Telephone. This document also covers the functional description for the work required to support a common User Interface for the IP Phone 2007.

68.3 Description

The IP Phone 2007 is a colour display telephone that offers innovative touch screen capability and a 5.7" diagonal display, delivering converged applications (voice, framed video and data such as customized web content) along with future SIP support via firmware download to a user's desktop. The IP Phone 2007 offers Bluetooth compatibility and USB support. The IP Phone 2007 is an extended functionality sibling of the IP Phone 2004. Refer to the following figure.

Disclaimer:

The Screenshot currently shows Incorrect labels: (i.e.) the Labels for the softkeys and f feature keys are swapped in a CICM environment.

Figure 1 IP Phone 2007

Figure 1 IP Phone 2007

IP Phone 2007 has an incorporated three-port hub, meaning that a desktop with an IP Phone 2007 and a computer requires only one connection to the network. In addition it is possible to draw power from the LAN.

This feature implements the screen displays to support basic functionality on the IP Phone 2007. Refer to the following table.

Table 1 IP Phone 2007 Configuration/menu matrix

Feature	**2007**
Display	
Pixels	240x320
Dimensions	5.7” diagonal
Backlight	CCFL
Technology	STN Colour
Greyscale/Colour	16-bit colour
Adjustable contrast	Yes

Adjustable backlight	Variable brightness
Touch panel	Yes

Number of LEDS	TBD
Mute Lamp	Yes Red
Headset lamp	Yes Red
Handsfree lamp	Yes Red
MW Lamp	Yes Orange/Red
Data Waiting Lamp	Yes blue
Link Lamp	Yes green
Feature Keys	Soft Defined
Nav Keys	4
Line Keys	Soft defined
Connectors	
Network Port	Gig
PC Port	Gig
10 pin KEM	Yes
Handset	Yes
Headset	Yes with detect
USB	Two
DC Power	Yes
Power Supply	
IEEE 802.3AF	Yes
Cisco Link Pulse	Yes
Cisco Mid-span	No
AC Adapter	Yes 48 volts DC
PowerDSine Mid-Span	Yes
Bluetooth	
Version	1.x
Profiles at GA time	Headset/HF
Audio	
Handsfree	Full Duplex
Headset	Yes

Handset	Yes
Wideband	Yes
USB	
Mouse	Yes
Keyboard	Yes
Flash Drive	Yes

68.3.1 Display

The IP Phone 2007 has a bit mapped and backlit 240x320 pixel colour STN display with 16 bit colour depth and integrated touch panel. The display of the IP Phone 2007 is not visible without the backlight.

Fonts are supported on this Display and the IP Phone 2007 has graphic capable displays and using a font representation of characters in place of the 5x7 dot matrix characters. The IP Phone 2007 sets are supporting a true font, Lucida Sans.

The contrast of this display is adjustable and On-off and brightness controls are provided.

The IP Phone 2007 is using cold cathode fluorescent lamp for backlit.

There is no reflected mode in the display of IP Phone 2007.

The CCFL is having the lifetime of 50,000 hours. To address Lifetime of CCFL, a firmware timer has been used to turn off the backlight after a period of inactivity. The user can customize the timeout period. The default timeout period is a long time and one more choice is no timeout.

The IP Phone 2007 doesn’t have any physical feature or soft keys but provide access to the functionality provided by the keys via the touch screen interface.

The display of the IP Phone 2007 looks same as the display of IP Phone 2004.

68.3.2 Keys

IP Phone 2007 supports the Key Expansion Module to provide access to an extended feature set.

The softkey and feature keys are not physically on the IP Phone 2007 but are available within the main screen display and are accessible by touching the screen. These keys provide access to the same functionality that is available on the IP Phone 2004.

68.3.3 Indicators

There are two Message Indicator Lamps on the IP Phone 2007, the amber indicator is intended to show when a voicemail message is waiting.

Message Waiting Indicator Orange/Red LED: Located at the top of the set. This LED indicates alerting and message waiting.

Data Waiting Indicator Blue LED: Located at the top of the set. This will be turned on while the user is on an active call.

Handsfree Indicator Red LED: Located on the front cover near the Handsfree key. Indicates when the handsfree is in use

Headset Indicator Red LED: Located on the front cover near the Headset key. Indicates when the headset is in use.

Mute Indicator Red LED: Located on the front cover near the Mute key. Indicates whether the terminal is on mute.

Link/Data Indicator Green LED: Located on the back cover near the Network Ethernet jack. Indicates when the Network etherport detects link and flashes for data activity.

68.3.4 Display Screens

The Following screen shots show some of Display screens of IP Phone 2007.

Figure 2 Services Key Panel

The above screen shot shows the services Key panel which is available in the IP Phone 2007. The services key panel offers various services. Example of such service is to view the Inbox and Outbox entries as well as gives facility to Transfer / forward the Call.

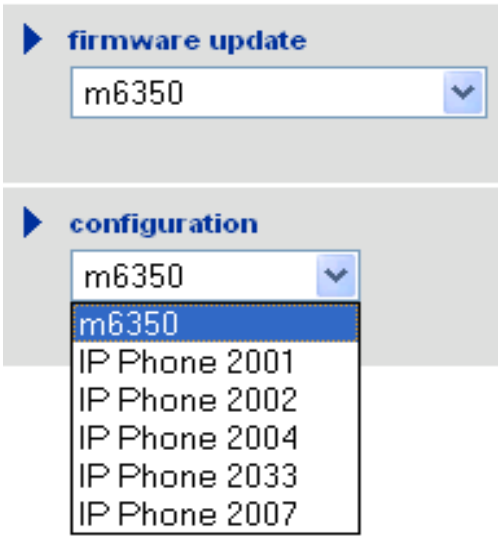
Figure 3 Navigation Key Panel

The Navigation keys provide us with the ability to use left and right keys during the text entry to navigate through the input string. The up and down arrow keys act as Home and End as found on the other IP Phone 2004.

Figure 4 Feature Key Panel

The feature keys are available via the touch screen and are used exactly the same manner as the IP Phone 2004.

68.3.5 Administration - Element Manager



The below screenshot provides the information of the firmware configuration e.g. firmware transfer protocol, Firmware load name and the version details of IP Phone 2007.

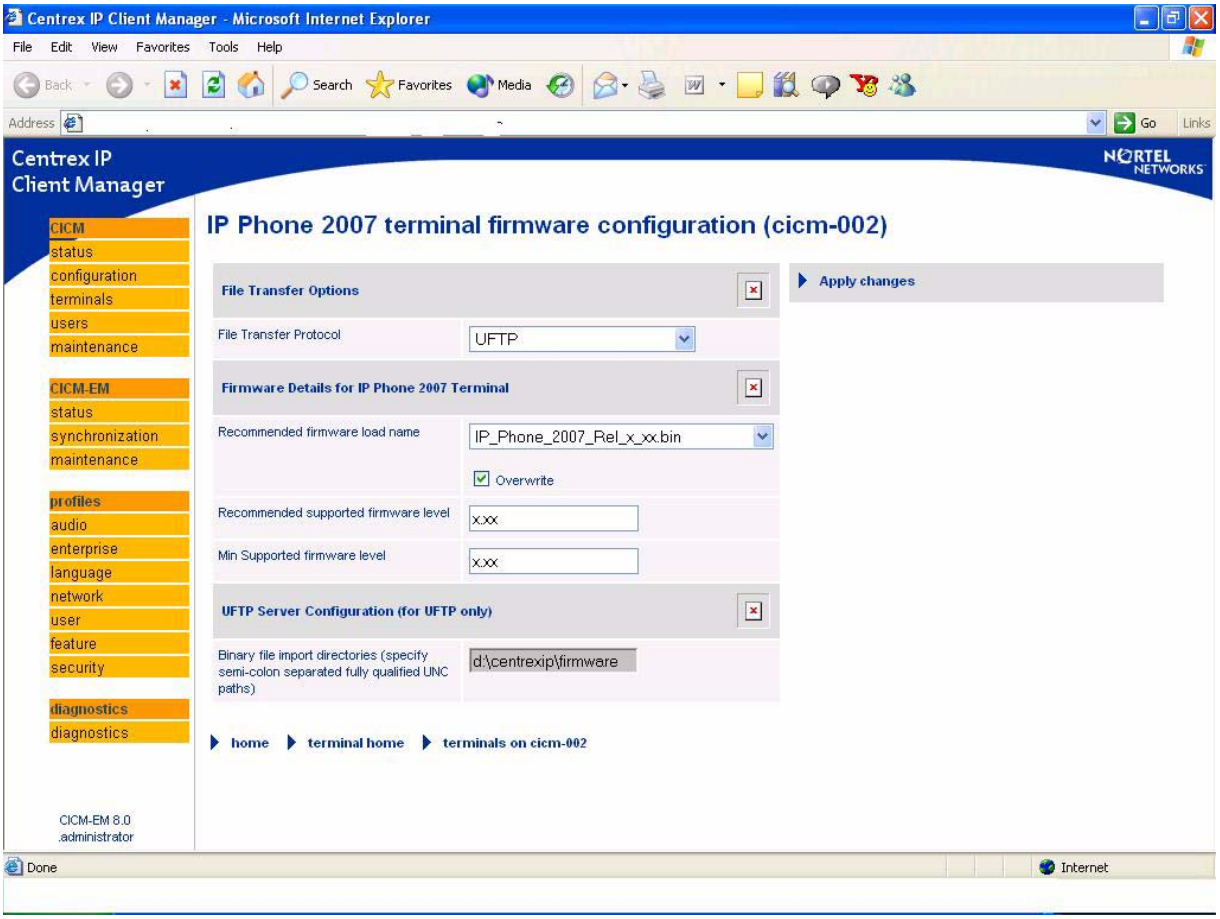


Figure 7 Terminal firmware upgrade page

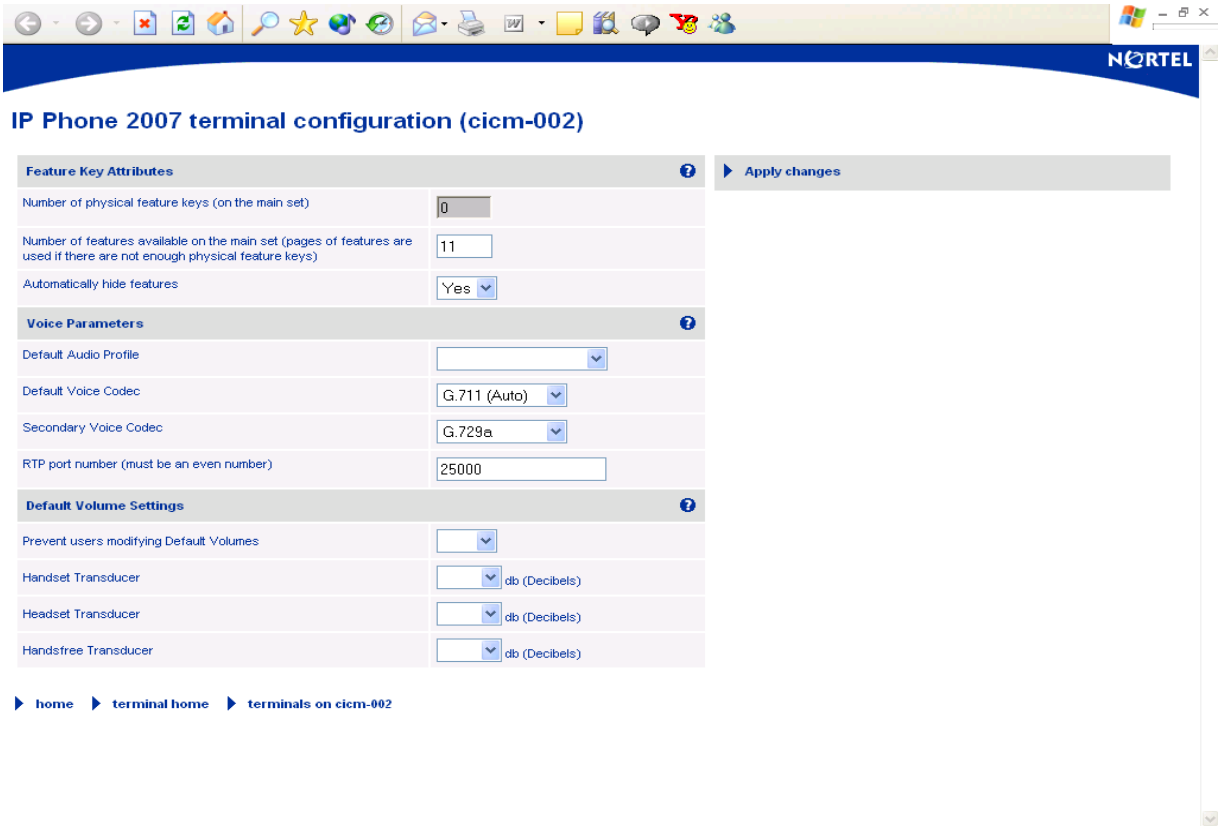

Figure 8 Terminal configuration page

The administration and configuration of the IP Phone 2007 use the same pages which are already provided for the IP Phone 2004 terminals. (See figure 7 and Figure 8.)

68.4 Interactions

68.4.1 Joint Sessions

The IP Phone 2007 is able to have a joint session with the m6350 Softclient. In this scenario, it will always adopt the master position in their master/slave relationship. In this case, the IP Phone 2007 will function in the same manner as the IP Phone 2004.

IP phone 2007 doesn’t support to have a joint session with another IP Phone 200x or Wave 1 Terminals.

68.4.2 ACD Call force

The IP Phone 2007 supports the ACD call force feature in the same manner as the IP Phone 2004.

68.4.3 SRG Support

The Survivable Remote Gateway (SRG) solution is based on the Business Communications Manager (BCM) platform and technologies. It allows distribution of trunking across the WAN so remote users can get dial tone from their local central office or from any other IP Telephony gateway hosted by Succession 1000. Local telephone numbers can be published, supporting a local presence within the community the remote office supports. This capability can also reduce unnecessary toll charges and provides required local trunking for Emergency 911 calls. Additionally, the Survivable Remote Gateway provides a full suite of IPbased data and routing capabilities including Network Address Translation (NAT), DHCP, Web caching, and firewall. IP Phone 2007 supports SRG feature in the same way as Phase 2 terminals.

68.4.4 Unistim Security

The IP Phone 2007 and CICM communicate using a stimulus protocol called Unistim. By interacting with the IP Phone 2007, an end user can use the services that are hosted by the CICM. The signalling protocol / communication between the terminal clients and the CICM were in the form of clear text and therefore susceptible to various signalling attacks. The purpose of the Unistim Security is to provide secure signalling communication (encryption / decryption / authentication) between the IP Phone 2007 and the CICM. The RTP (voice) path is not affected (i.e. remains non-secured).

68.5 Software Requirements or Dependencies

The IP Phone 2007 supports standard TFTP or Nortel UFTP (Unistim FTP) for firmware download. In case of UFTP, the CICM must be able to recognize, store and upload 2007 firmware

68.5.1 Firmware Download

The IP Phone 2007 has upgradeable firmware. The firmware may be upgrade by the following methods.

- The CICM can query the FW version and direct the phone to conduct a firmware download from a TFTP server or download the firmware using UFTP.
- A USEC secured CICM can direct the phone to conduct a firmware download under the protection of Secure UNIStim.
- The phone may be directed to a TFTP server either manually, by full DHCP or a .cfg file to download new firmware.

Firmware may be downloaded through the console port.

69: Functional description (FN): A00009364

69.1 Feature name and Feature ID

A00009364 - CICM End-of-Call QoS Reporting

69.2 Description

In Voice over IP networks, Quality of Service (QoS) can be adversely affected by the components in the network. Unlike TDM networks where the voice quality is consistent for all calls, VoIP networks can experience different voice quality on all calls.

Per call QoS statistics can be used for the following:

- Network engineering
- Trend analysis
- Trouble-shooting network problems
- Service Level Agreement (SLA) validation

The CICM reports QoS statistics as shown in Figure 1, and can be described as follows:

- The CICM reports the QoS statistics at the end of the call. Each ephemeral associated with a call reports QoS statistics separately. When the GWC instructs the CICM to subtract the ephemeral termination QoS statistics are sent to:
  - — The gateway controller (GWC) over H.248
  - — The extended QoS server (a predefined ip address and port number) over UDP in an ANSI based XML format.
- The GWC reformats the QoS statistics reported by the gateway into a binary format and sends the QoS report to the QoS Collector Application (QCA).
- The QCA manages QoS streams from multiple GWCs, reformats the data to an IPDR format and stores the data to disk.

QoS statistics are accumulated on supported clients/terminals whilst a call is active. If a call is placed on hold the QoS statistics are frozen (no more statistics are accumulated) until the call is resumed.

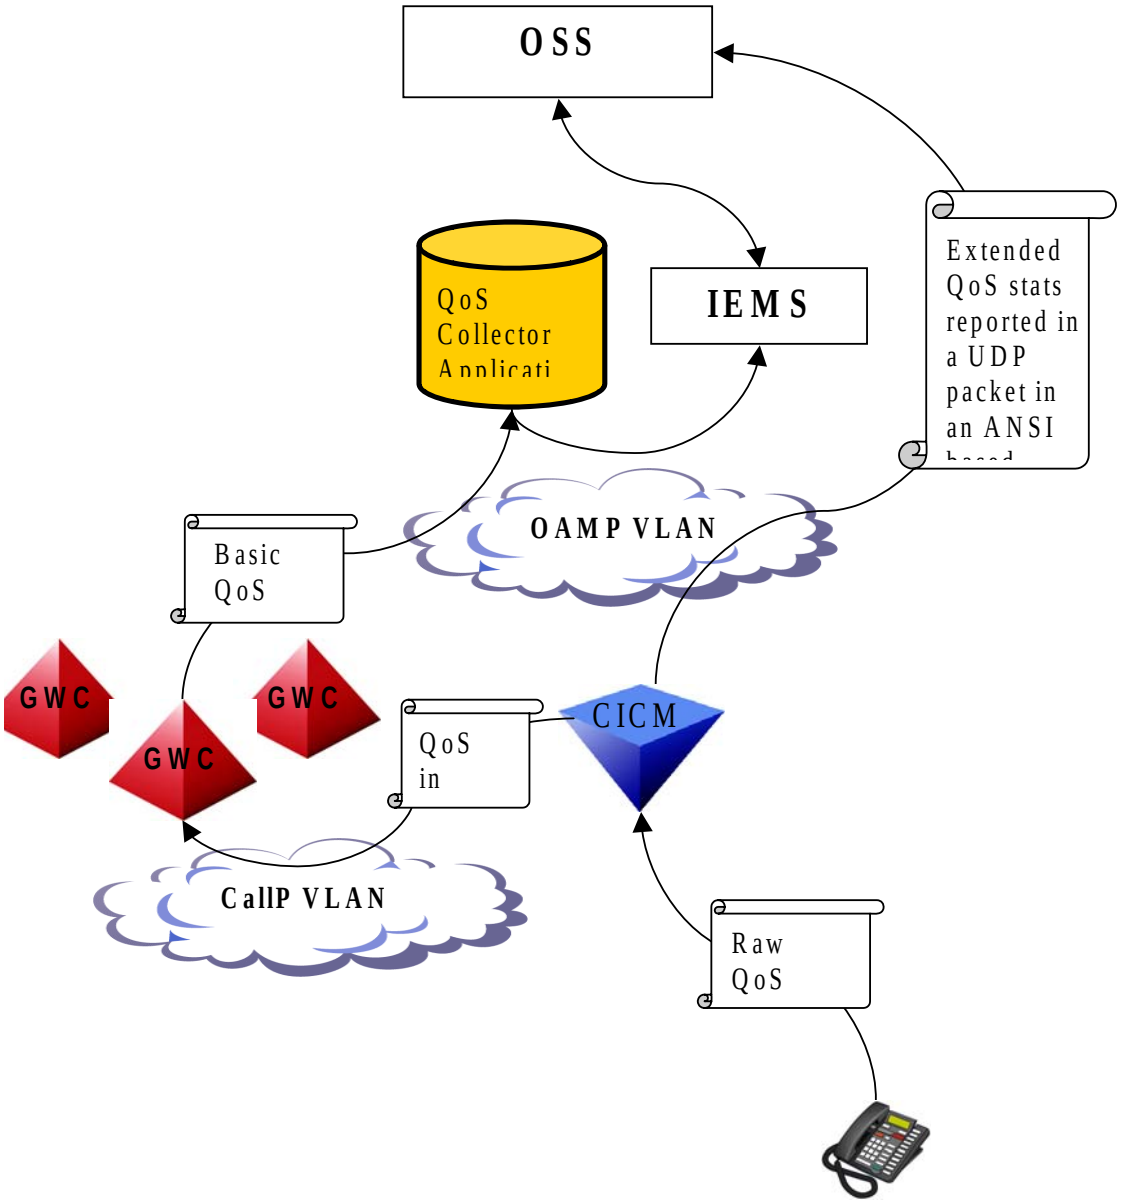

Figure 1 CICM QoS reporting

See Table 1 for a list of supported QoS parameters[1][2].

Note: [1]: Phase 1 terminals support version 1 QoS reporting only. Phase 2 terminals support version 2 “extended” QoS reporting. A complete list of QoS statistics is shown in Table 1. See section 2.5 for further details on supported client/terminal types and firmware requirements.

Note: [2]: Statistics which cannot be obtained from a client/terminal are reported upwards (to the GWC and extended QoS server) with a value of ‘0’.

Table 1 QoS parameters reported

Terminal / Client **QoS reporting version**					**CICM** **QoS Report type**	
1	**2**	**Parameter Name**	**Extended report abbreviation**	**Description**	**Basic** **(QCA)**	**Extended** **(extended QoS server)**
X	**X**	**Jitter Average**	JA	Average variation in packet arrival times due to transmission (routing, queuing delay, etc…) through the network. Represented in 1/65536 of seconds, of the incoming RTP packets inter-arrival time.	X	X
X	**X**	**Jitter High Water Mark**	JHW	Max variation in packet arrival times due to transmission (routing, queuing delay, etc…) through the network. Represented in 1/65536 of seconds, of the incoming RTP packets inter-arrival time		X
X	**X**	**Far End Originated Loss**	FEOL	Far end orginated loss	X	X

X	**X**	**Round Trip Average**	RTA	Average RTCP packets round trip time. Represented in 1/65536 of seconds, of the incoming RTCP packets round trip time		X
X	**X**	**Round Trip High Water Mark**	RTHW	Max RTCP packets round trip time. Represented in 1/65536 of seconds, of the incoming RTCP packets round trip time.		X
	X	**Local Silence Suppression**	SS	Indicates if silence suppression was used.		X
	X	**Local Rx and Tx Codec Type**	rC/tC	Codec Type		X
	X	**Local Rx and Tx Packetization Rate**	rPR/tPR	Frame duration in milliseconds.		X
	X	**End System Delay**	ESDA	most recently specified/calculated end system delay in milliseconds. This includes the sample accumulation and encoding delay, as well as the average jitter buffer delay, decoding and playout delay.		X
	X	**Average One Way Delay**	OWDA	average one-way delay in milliseconds.	X	X
	X	**Maximum One Way Delay**	OWDM	maximum one-way delay in milliseconds.		X

	X	**Average Noise Level**	NLA	ratio of the silent period background noise level to overflow signal power, expressed in decibels; 127	X
	X	**Average Signal Power**	SPA	ratio of the signal level to overflow signal level, expressed in decibels; measured only for packets containing speech energy.	X
	X	**Echo Return Loss**	ERL	sum of the measured echo return loss (ERL) and the echo return loss enhancement (ERLE) expressed in dB; the ratio of a transmitted voice signal that is reflected back to the talker.	X
	X	**Listening R factor**	LRF	direct measure of the call quality or transmission quality, and incorporate the effects of CODEC type, packet loss, discard, burstiness, delay etc.; this metric describes the segment of the call that is carried over this RTP session.	X

	X	**Conversational R factor**	CRF	segment of the call that is carried over a network segment, external to the RTP segment, for example a cellular network; relates to the outward voice path from the Voice over IP termination for which this metrics block applies.	X
	X	**Listening Quality MOS**	LM	estimated mean opinion score for listening quality. The valid scale is 10 to 50 representing MOS 1.0 to 5.0, respectively.	X
	X	**Conversational Quality MOS**	CM	estimated mean opinion score for conversational quality. The valid scale is 10 to 50 representing MOS 1.0 to 5.0, respectively.	X
	X	**Burst R factor**	BRF	R factor during a burst period; a burst is defined as a longest sequence of packets bounded by lost or discarded packets	X
	X	**Average Burst Density**	BDA	average percentage of MIU's lost or discarded during burst periods. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X

	X	**Burst count**	BC	number of bursts that have occurred on the call	X
	X	**Average Burst Length in MS**	BLA	average length of all burst periods in milliseconds that have occurred on the call	X
	X	**Gap R factor**	GRF	R factor during a gap period; a gap is defined as the period of time between two bursts.	X
	X	**Average Gap Density**	GDA	average MIU'S lost or discarded within gap periods. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X
	X	**Average Gap Length in MS**	GLA	average length in milliseconds of all gaps that have occurred on the call.	X
	X	**Average Loss Rate**	LRA	total average percentage of MIUs lost and/or discarded. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X
	X	**Average Network Loss Rate**	NLRA	total average percentage of MIUs lost in the network. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X

	X	**Average Discard Rate**	DRA	total average percentage of MIU's discarded. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X
	X	**MIU Duration**	MD	duration of each MIU, in milliseconds	X
	X	**MIU per packet**	MPP	total number of MIU's in each RTP packet	X
	X	**MIU Loss percentage**	MLP	percentage of MIUs handled by the call channel that were lost in the network. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X
	X	**MIU Discard percentage**	MDiP	percentage of MIUs handled by the call channel that were discarded by the endpoint. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X
	X	**MIU Out of order percentage**	MOOOP	percentage of MIUs handled by the call channel that is discarded by the endpoint. This value is an 8:8 fixed-point value (i.e. scaled by 256).	X

	X	**MIU Duplicate percentage**	MDP	percentage of MIUs handled by the call channel that is discarded by the endpoint. This value is an 8:8 fixed-point value (i.e. scaled by 256).		X
	X	**Number of RTP packets rx/tx**	rP/tP	Number of RTP packets received and transmitted	X	X
	X	**Number of RTP packets out of order**	rPOOO	Number of RTP packets received out of order		X
		Octets rx/tx	rO/tO	Octets sent and received. NOTE: This parameter is not currently supported by any terminal types. This value will be set to '0' in all reports.	X	X

69.2.1 Extended QoS statistics

The complete list of QoS statistics[1] displayed in Table 1 can be obtained by configuring the ip address and port number of an extended QoS server on the element manager (see section 3.2.1 for further details on datafill). Extended QoS statistics for each call half will then be reported to the extended call server. Basic QoS statistics will still be reported to the QCA.

The extended report is sent to the configured destination by UDP (using the CICMs admin ip address, port number 34366) in an ANSI based XML format. An example extended QoS XML report is displayed below:

Note: Depending on the client/terminal type hosting the call. Please see section 2.5 for further information.

The header information for the extended QoS XML report is described in Table 2.

Table 2 Extended QoS report header information

Extended QoS XML header tag	Description	Format	Example
ST	Start time (Universal time – UTC)	yyyy-dd-mm**T**hh:mm:ss**Z**	**2005-18-03T16:19:06Z**
ET	End time (Universal time – UTC)		
Host	Machine host name	CICM-xxx-x	CICM-180-A
LEN	LEN	CICM xxx x xx xx	CICM 180 0 00 01
Ip	Ip address of the client	xxx.xxx.xxx.xxx	47.121.122.123

69.2.2 Datafill

QoS reporting is enabled/disabled from the GWC element manager (see Figure 2).

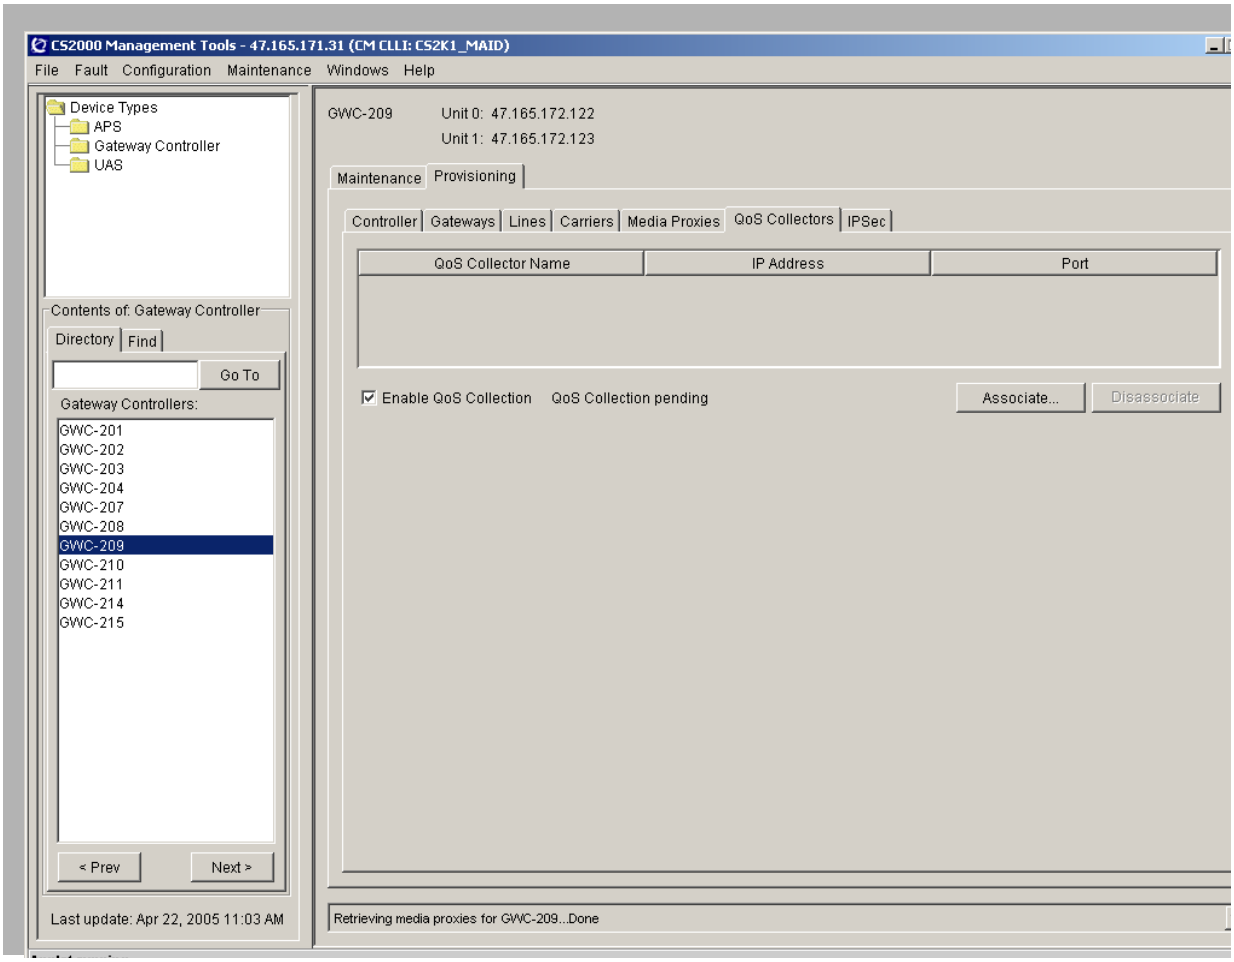

Figure 2 GWC element manager – Enabling/Disabling QoS

Extended QoS reporting is enabled/disabled from the CICM element manager (see Figure 3). Extended QoS statistics will only be sent if a destination ip address and port-number have been data-filled on the CICM element manager global settings page.

Modifications to the extended QoS ip address and port number are picked up dynamically (within 2 minutes) and do not require a reboot.

To disable extended QoS reporting both the extended ip address and port number must be deleted.

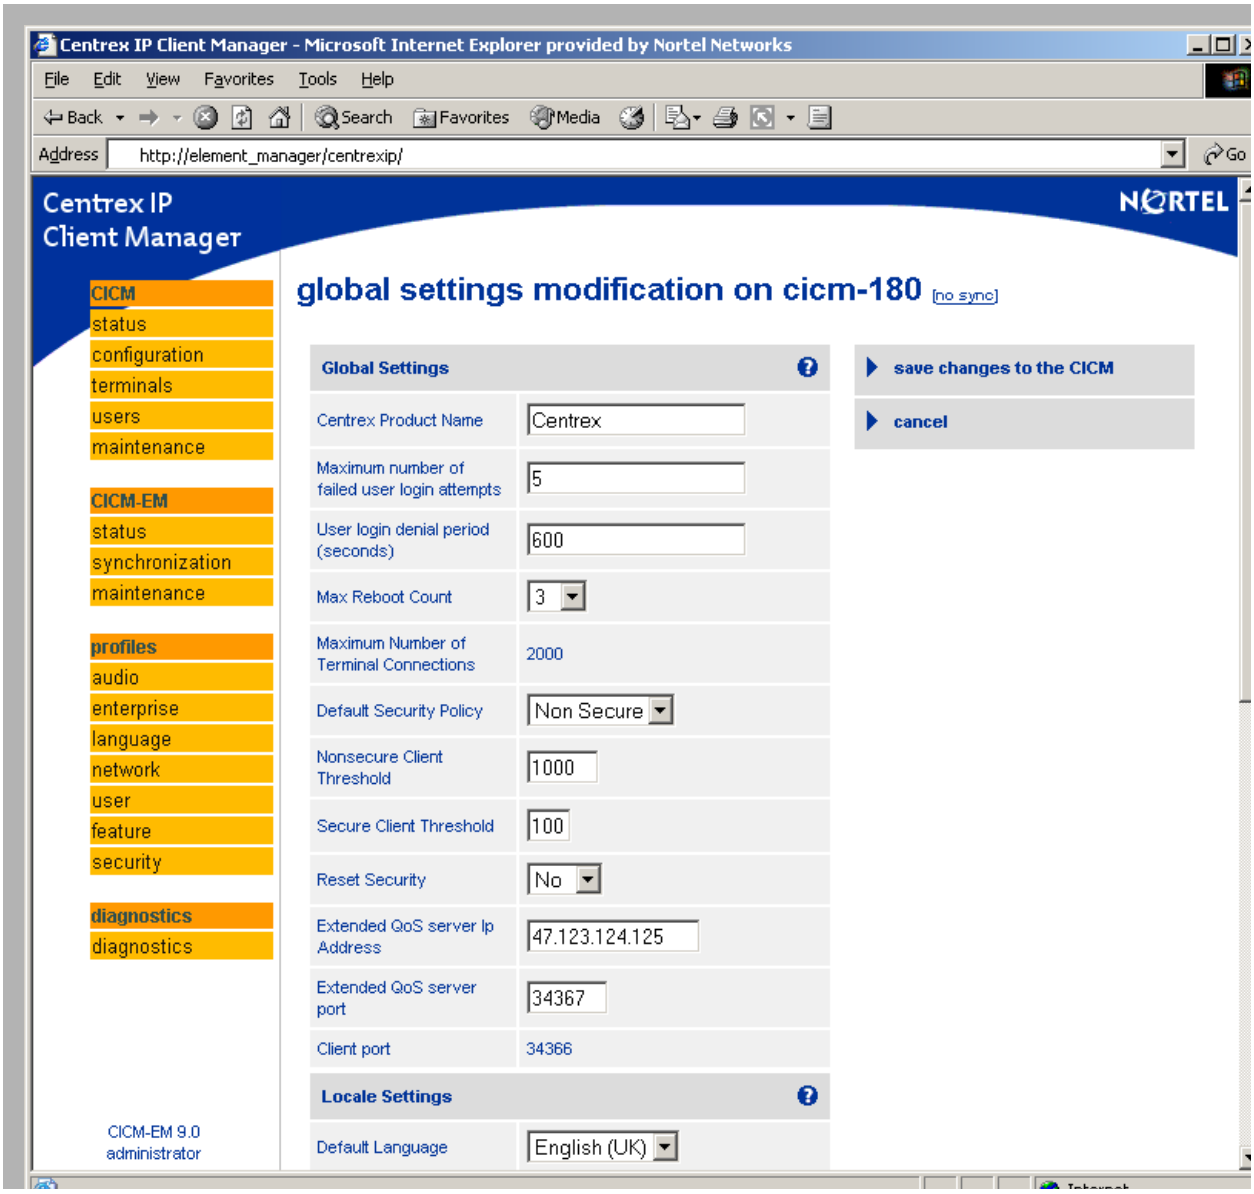

Figure 3 CICM element manager - Enabling/Disabling extended QoS reporting

69.3 Hardware Requirements or Dependencies

QoS Collector Application QCA

69.4 Software Requirements or Dependencies

Not Applicable

69.5 Limitations and restrictions

Terminal type	Version 1 QoS report supported		Version 2 “Extended” QoS report supported (Phase 2 terminals only)	
	Y/N	Minimum firmware version	Y/N	Minimum firmware version
i2001	Y	3.90	Y	3.90
i2002	Y	1.74	Y	3.90
i2004	Y	1.74	Y	3.90

70: Functional description (FN): A00009365

70.1 Feature name and Feature ID

A00009365 - Mid-call Session Description Protocol (SDP) renegotiation

70.2 Description

70.2.1 Pre-answer and mid-call SDP renegotiation

This activity introduces support for pre-answer and mid-call IP address and codec renegotiation in CICM 9.0, and eliminates the requirement for a Media Portal for CICM lines in a flat network.

During call setup, CICM negotiates the codecs, packetisation times and destination IP information via the exchange of Session Description Protocol (SDP) messages with the far-end. Currently, CICM is unable to process SDP renegotiation attempts from the peer gateway. This causes problems when interworking with gateways which rely on SDP renegotiation to change codecs or destination IP address pre-answer or mid-call.

Prior to CICM 9.0, the lack of support for SDP renegotiation on the CICM causes problems when interworking with Multimedia Call Server (MCS), where an SDP renegotiation attempt can be triggered when MCS features are activated. This activity introduces support for pre-answer and mid-call IP address and codec renegotiation required when interworking with the MCS.

Figure 1 CICM interworking with MCS

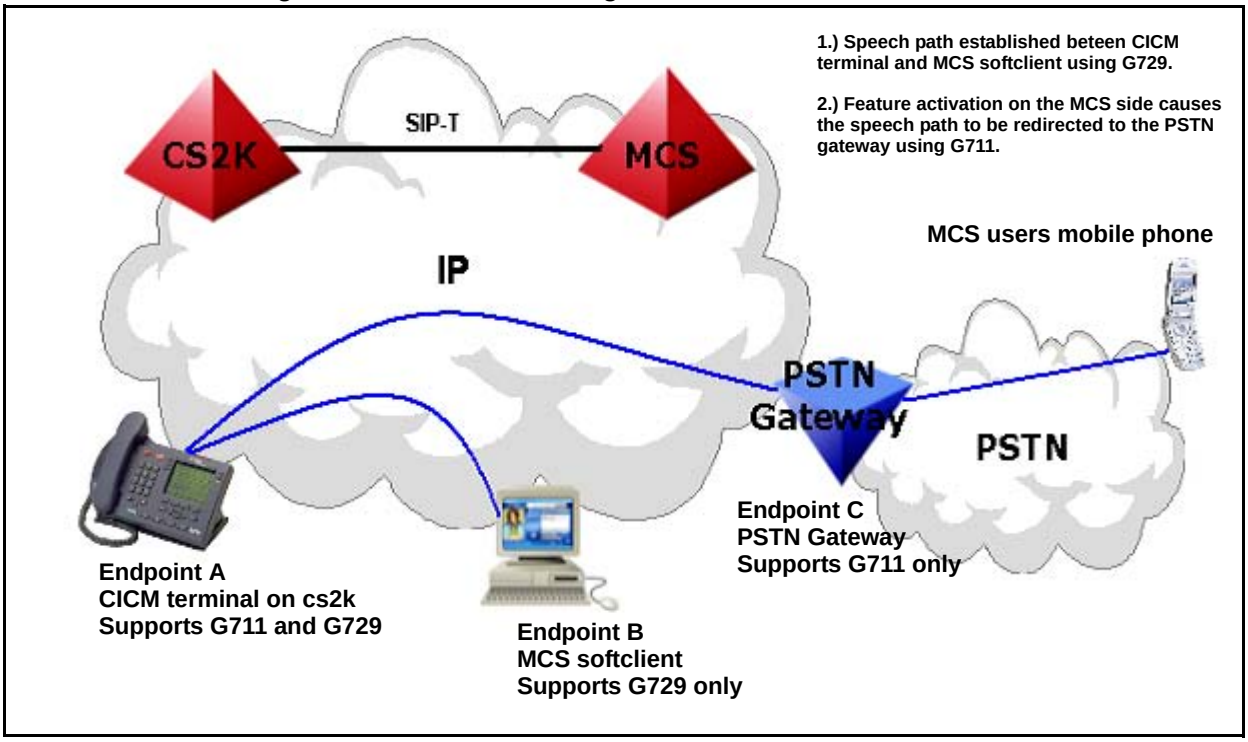

Figure 1 illustrates an example of how feature activation on the MCS can trigger changes in the destination IP address and codecs. This example shows a single CICM client hosted on the cs2k, and a softclient and PSTN gateway hosted on the MCS. The cs2k and MCS are connected by a SIP-T link.

Pre-answer IP address and codec renegotiation:

- CICM terminal calls MCS softclient. Speech path is negotiated to use G729, and terminate at the MCS softclient.
- MCS user does not answer, MCS softclient re-directs the call to the MCS user mobile via the PSTN gateway. Speech path is renegotiated to use G711, and terminate at the PSTN gateway.

Post-answer IP address and codec renegotiation:

- CICM terminal calls MCS softclient (or vice-versa). Speech path is negotiated to use G729, and terminate at the MCS softclient. MCS user answers the call.
- MCS user has to leave, and redirects the call to their mobile. Speech path is renegotiated to use G711, and terminate at the PSTN gateway.

70.3 Hardware Requirements or Dependencies

This activity does not introduce any new hardware requirements or dependancies.

70.4 Software Requirements or Dependencies

This activity does not introduce any new software requirements or dependancies.

70.5 Limitations and restrictions

This activity introduces support for IP address renegotiation at the CICM gateway level only. It does not imply that IP address renegotiation is supported by succession in general. Currently, the GWC Media Portal insertion software does not have the capability of processing mid-call destination IP address changes. For this reason, the MCS must be configured to always insert a Media Portal when interworking with the cs2k. This has the effect of shielding the cs2k from the destination IP address change, as the cs2k directs its audio stream to the MCS portal for the duration of the call.

70.6 Glossary

Term	Description
CICM	CentrexIP Client Manager
SDP	Session Description Protocol
MCS	Multimedia Communications Server
GWC	Gateway Controler

71: Functional description (FN): A00009375 & A00009376

71.1 Feature name and Feature ID

A00009375 & A00009376: CICM Third-party Corrective Content Patching & CICM Selective Binary Component Patching

71.2 Description

71.2.1 Overview

In pre-SN09 loads, all corrective content is delivered via the Maintenance Release (MR) process. In SN09, the MR process will be complimented with new functionality to allow the application of patches containing application, operating system or third party corrective content to the CICM or CICM-EM.

Patches will be built and released by Nortel CICM GNPS, and will be applied onto the CICM or CICM-EM, via the maintenance pages on the CICM-EM.

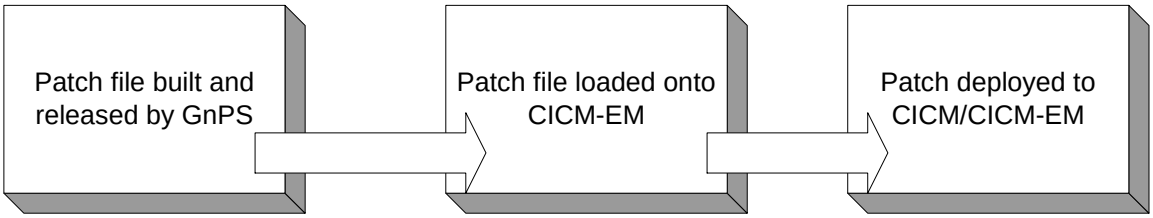

Figure 1 Patch Delivery Overview

71.2.2 Detail

The patching process will compliment the existing MR process by delivering corrective content quickly and efficiently in between the normal MR deliveries. From an end-user perspective the main differences will be as follows.

Maintenance Releases

- Will be delivered at regular intervals
- May contain a large number of corrective content fixes
- May contain a combination of application, operating system or third party corrective content.
- Will replace ALL application binaries (CICM/CICMEM software) on the system to which it is applied.
- The installation of an MR always requires at least one system restart.

Patches

- Will be delivered on an ‘as needed’ basis
- Will contain a single fix for a specific issue
- May contain application, operating system or third party corrective content. But typically not a combination.
- Will only replace application binaries / make other system image changes needed to deliver the corrective content.
- The installation of a patch will not always require a system restart.

71.2.3 Patch Delivery and Application

Nortel GNPS will deploy a patch to a customer in the form of a single patch file and a 128-bit MD5 checksum. The patch file and the checksum will be distributed separately in order to ensure the integrity of the patch file. The checksum of a file will be displayed upon the CICM EM web page once a patch has been selected, the craftsperson may wish to confirm that the number shown is the same as that expected.

This md5 checksum system described in the last paragraph will also be in place for Maintenance Releases.

71.2.3.1 Patch Delivery

The patch file will be delivered to the customer either via electronic transfer or on physical media. The MD5 checksum will be delivered to the customer via e-mail or through publication on an externally accessible Nortel website.

Nortel has corporate wide guidelines on the categorisation and description of Corrective Content (CC). Regional Patch Solutions (RPS) is our interface to the criteria and practice.

RPS offers the PatchFeed tool for submission of CC and this will be used by GnPS to deliver patches to the Nortel website, customer drop-boxes etc. once the patch has been built.

The patch that PatchFeed takes is encapsulated in metadata before being sent on. This metadata is in addition to the metadata added to the CAB files themselves and serves to identify the patch; it’s category, status and applicability conditions to RPS systems.

RPS defined categories for CC are:

- GEN--General content (mass deployment)
- EMG--Emergency content (accelerated mass deployment)
- ACT--Feature rich content (mass or specific Customer deployment)
- LTD--Limited content (specific Customer deployment)

- DBG--Debug content (specific Customer deployment)
- OBS--Obsolete content
- OBE--Obsolete Emergency content

Patches will fall under the GEN, EMG, LTD or DBG category, dependent upon the function of the patch in question.

The RPS statuses are:

- V--VO content (limited deployment)
- R--Released (mass deployment – depending on category)

Patches may be released with either of these statuses.

71.2.3.2 Patch Application

Upon receiving the patch file, the customer will transfer the file into the patching directory on the Master Element Manager (D:\CentrexIP\support\patches) via secure file transfer. Once there the patch can be applied to any suitable node that is under the management of the EM.

All patch management and installation will be carried out under the Element Manager Maintenance pages.

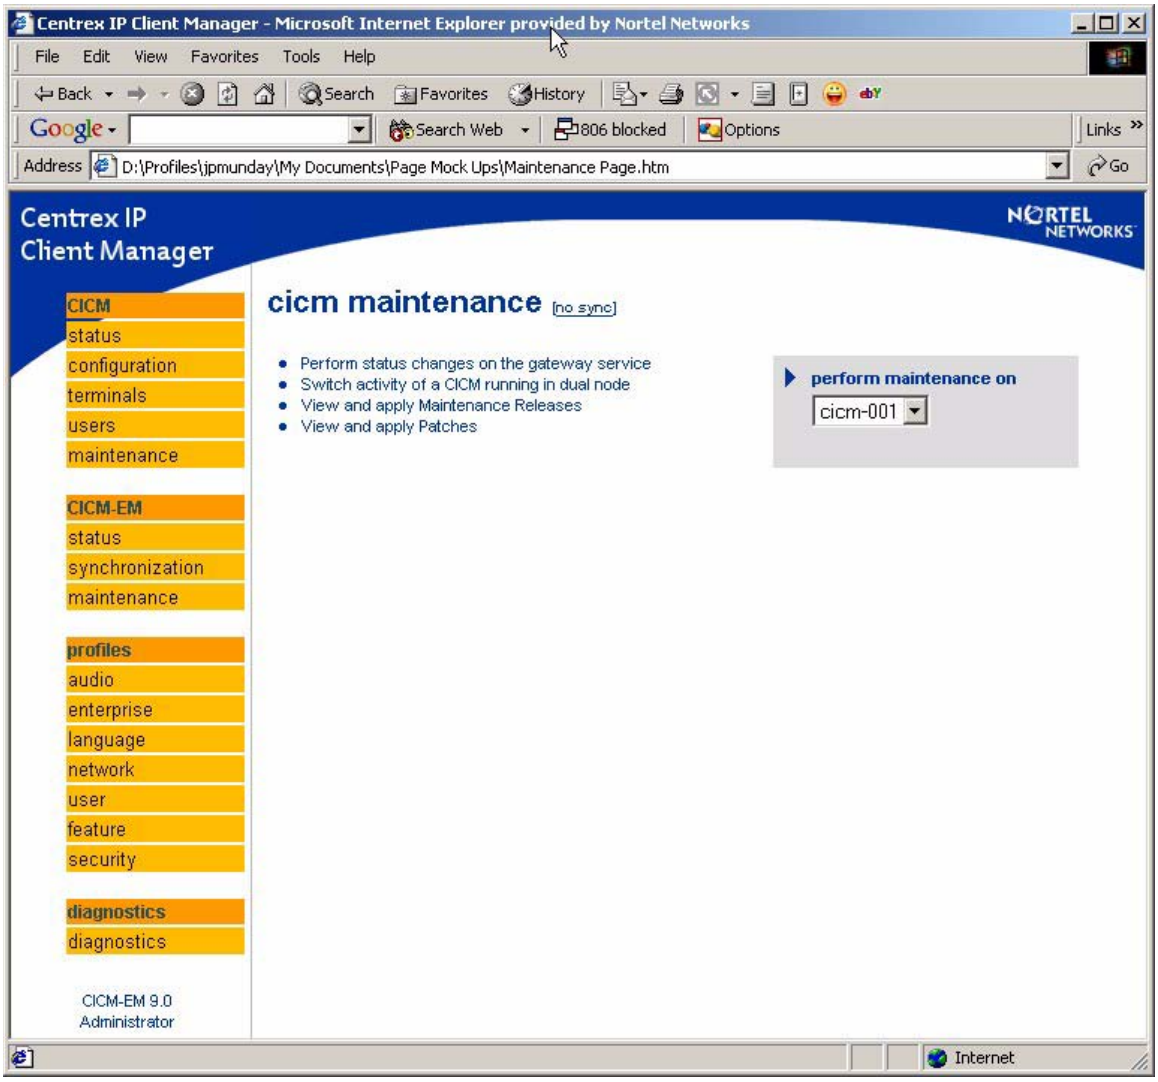

Figure 2 EM Maintenance Page

The diagram below shows the new web page layouts before and after the implementation of the SN09 patching features.

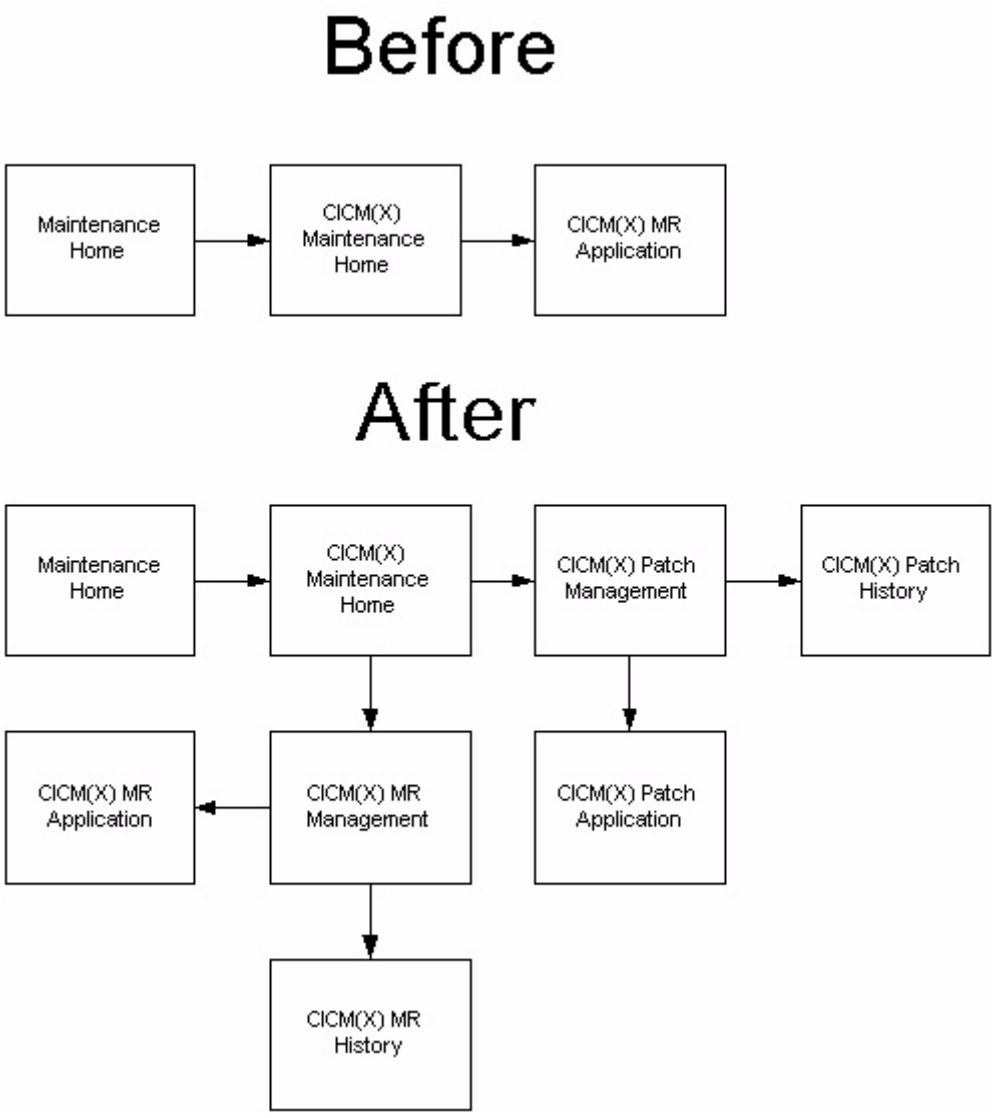

Figure 3 New Webpage access diagram

Once a user has selected the CICM node that they wish to carry out maintenance on they will be taken to the corresponding maintenance status page. The examples that follow show the maintenance and patching pages for a CICM, however the procedure and pages for applying a patch to a CICM-EM will be similar.

As with previous releases, the Maintenance Status page will display maintenance information for this CICM. In addition a new link will be available to allow access the patch management pages for a particular node on this CICM.

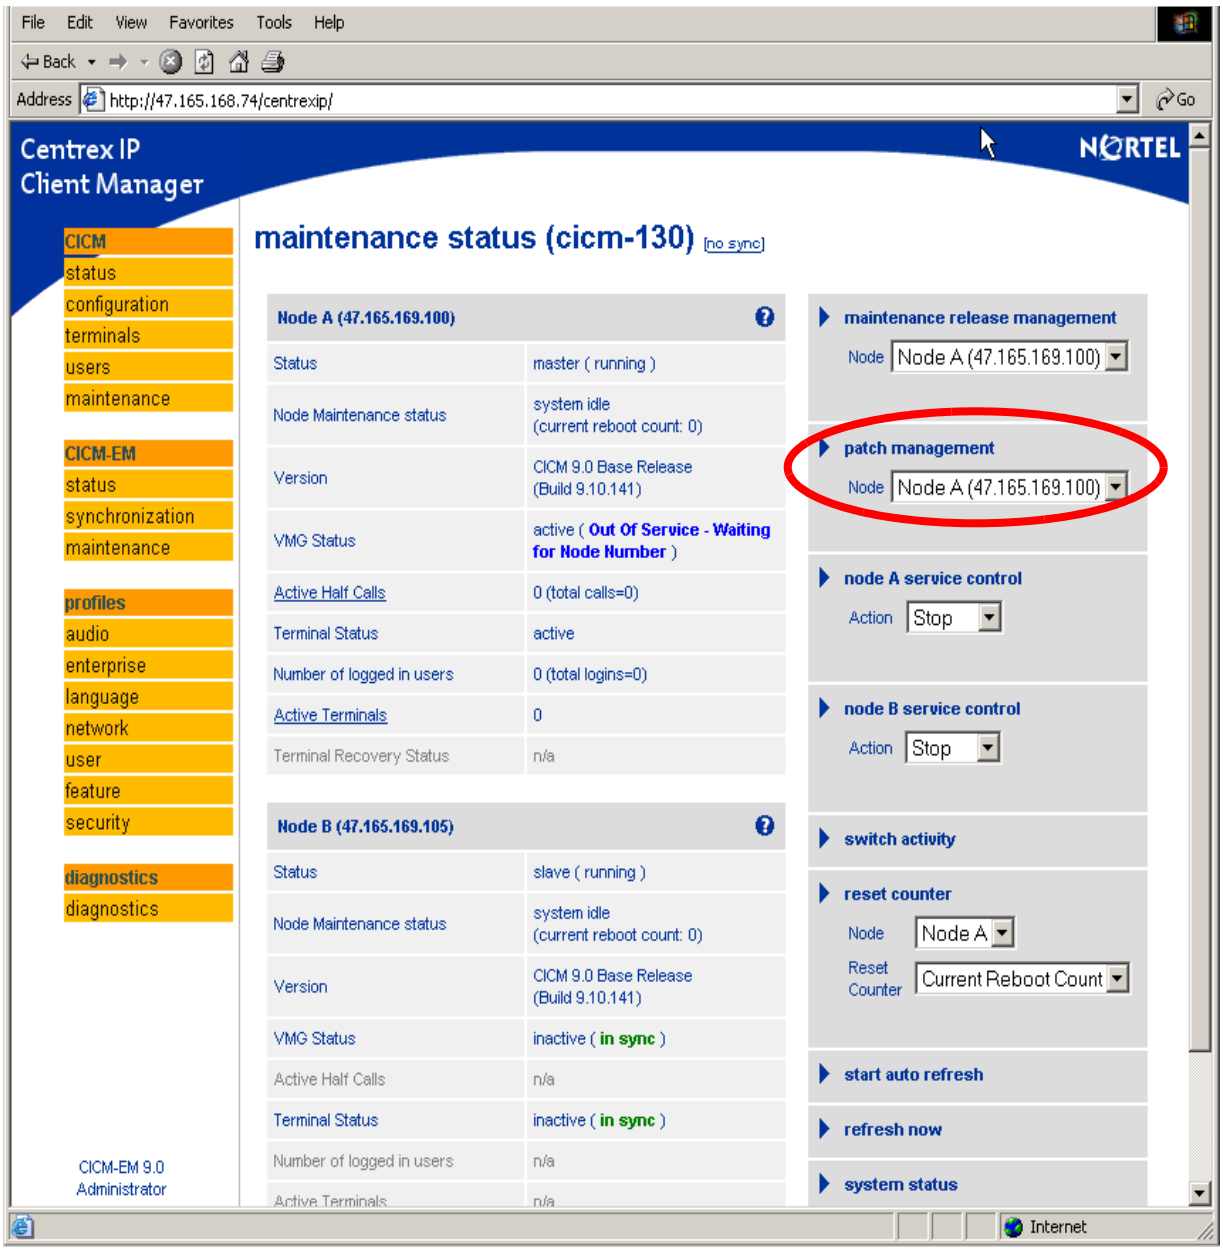

Figure 4 Maintenance Status Page

Selecting this link will take the user to the Patch Management page shown below…

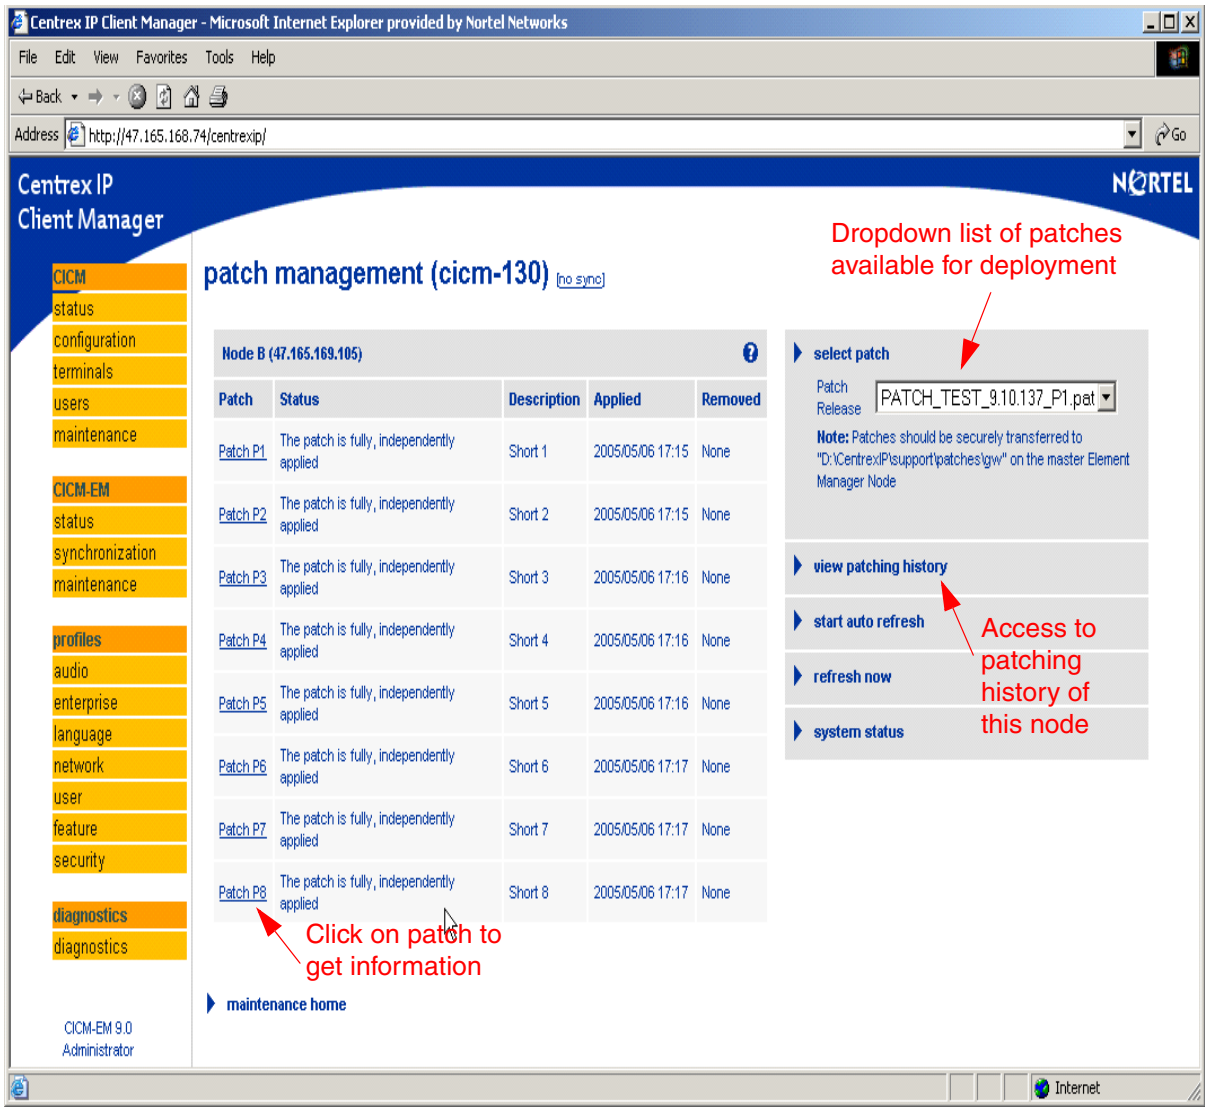

Figure 5 Patch Management Page

The patch management page shows a table of all patches that have been applied to this node **since the last Maintenance Release,** along with their application date and time, removal date and time (if applicable), a brief description and their status. This list is alphabetically ordered by Patch ID. Note that this Microsoft Windows convention of ordering will mean that patches 1, 2 and 10 will be ordered 1, 10 and 2. This ordering is independent of the order in which the patches were applied. To determine the application order the reader is referred to the paragraphs further down concerning the patch history page.

All patches will have a status of either ‘Applied’ – indicating that the corrective content of this patch is currently present on the system, ‘Removed’ – indicating that the corrective content of this patch has been removed by another patch or ‘Subsumed’ – indicating that the corrective content of the patch has been wholly subsumed by a later applied patch.

All patches copied into the patching directory on the Master Element Manager (D:\CentrexIP\support\patches) will be present in the ‘Select Patch’ dropdown menu.

When the user selects the patch to be applied from the dropdown list, they are taken to the patch application page shown below.

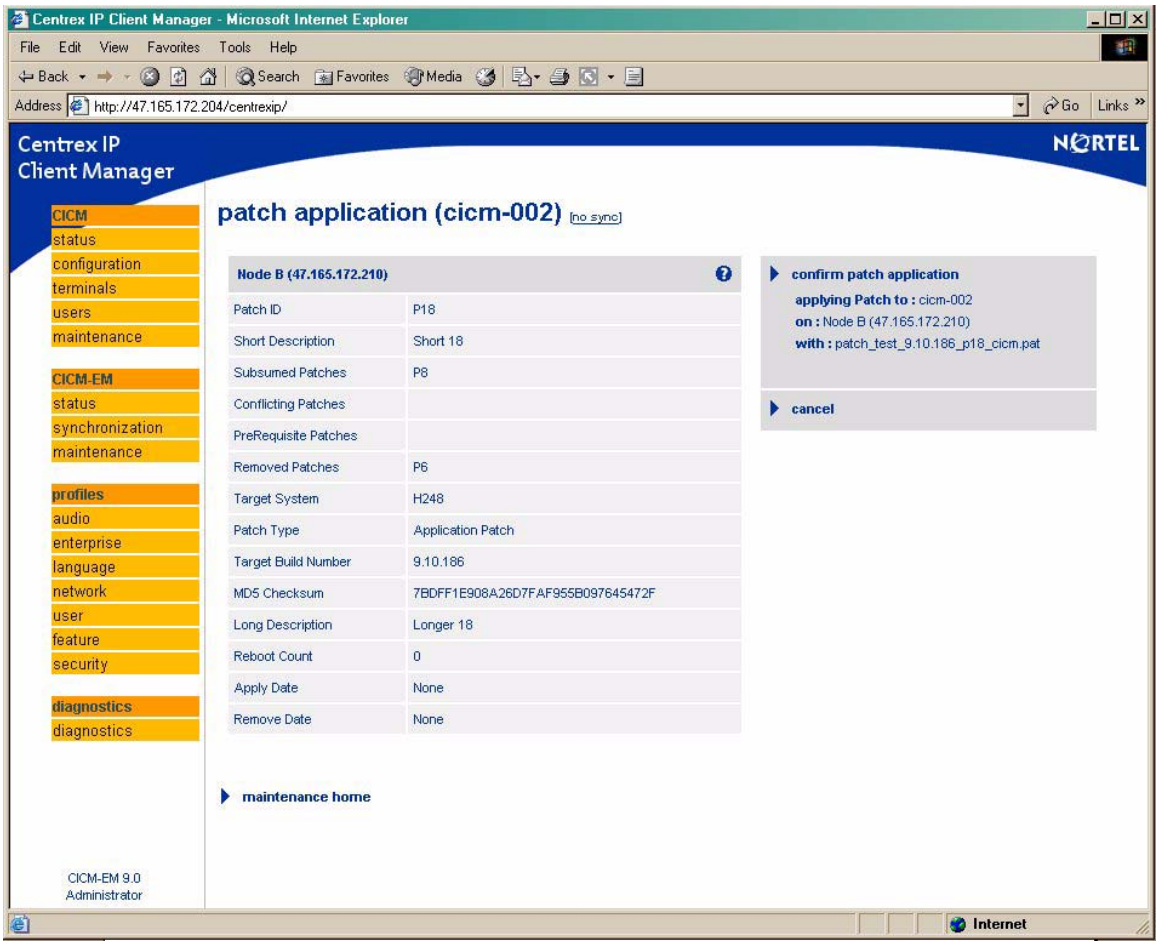

Figure 6 Patch Application Page

The Patch Application page will display all the details of the selected patch. Any conditions that would prevent this patch from being installed will be displayed in the right hand tab where the ‘confirm patch application’ link would normally appear.

If all Conflicts and Dependencies have been satisfied then the ‘Confirm Patch Application’ link will be enabled in order to allow patch application. Otherwise the link will be disabled along with details of why the patch cannot be applied, as shown.

The patch application page will display the following information.

Patch ID	The unique identifier for this patch
Target System	Indicates which type of node this patch can be applied to. This can be ‘H248 CICM’ or ‘CICM EM’. If this patch is not valid for this node type the ‘confirm patch application’ link will be disabled and replaced with a message indicating the conflict.
Target Build Number	Indicates the target release that this patch can be applied to. If this patch is not valid for this node type the ‘confirm patch application’ link will be disabled and replaced with a message indicating the conflict.
MD5 Checksum	The MD5 checksum of this patch file. The user should check that this checksum matches the checksum provided by Nortel for the patch file before applying the patch.
Description	A brief description of this patch
Conflicts	A list of patches with which this patch will conflict. Conflicts preventing installation will be shown in the right hand frame. *For more information see the section on Patch Version Control later.*
Dependencies	A list of patches upon which this patch is dependent. Dependencies preventing installation will be shown in the right hand frame. *For more information see the section on Patch Version Control later.*
Subsumes	A list of patches which are subsumed by this patch. Contained elements preventing installation will be shown in the right hand frame. *For more information see the section on Patch Version Control later.*
Removes	A list of patches which will be removed by this patch. Removed elements preventing installation will be shown in the right hand frame. *For more information see the section on Patch Version Control later.*
Reboot Count	The number of times the target system will reboot during the course of the patch application. See section “Selective Service Start-up and Shutdown” on page 610.
Short Description	The ‘patch title’ giving basic information on what this patch does.
Longer Description	More detailed information released by GNPS providing technical information on the patch.

Once the target system and all conflict and dependency checking as been satisfied, it is the responsibility of the user to ensure that the checksum

displayed for the patch file is identical to the checksum provided by Nortel before applying the patch.

Once this is done, the patch can be applied by clicking on the ‘Confirm Patch Application’ link. The user will then be taken to the Maintenance Status page where the status on the patch installation will be displayed. Patches can only be applied to the Slave node of a CICM or CICM-EM pair. However, application to the Master is permitted if the Slave is unavailable. The user will be shown a warning message in this scenario.

Assuming that the patch application is successful, the patch will appear on the Patch Maintenance page with a status of ‘Applied’. The user can now run sanity on the system or test the functionality of the patch.

If the patch installation fails for some reason, the patch will remain unapplied and will not be added to the list of applied patches on the Patch Management page. An entry will not be added into the patching history page. If the patch application failed during consistency checking the system service will not have been nor will be affected. If the application failed whilst the patch was actually being applied maintenance action may then be required to return the node to full service. In the event of a patch application installation failure in this latter case, customers are strongly recommended to contact the next level of support.

If the user wishes to view more detailed information on a previously applied patch, they can click on the Patch ID on the Patch Maintenance page. This will display the patch information page shown below.

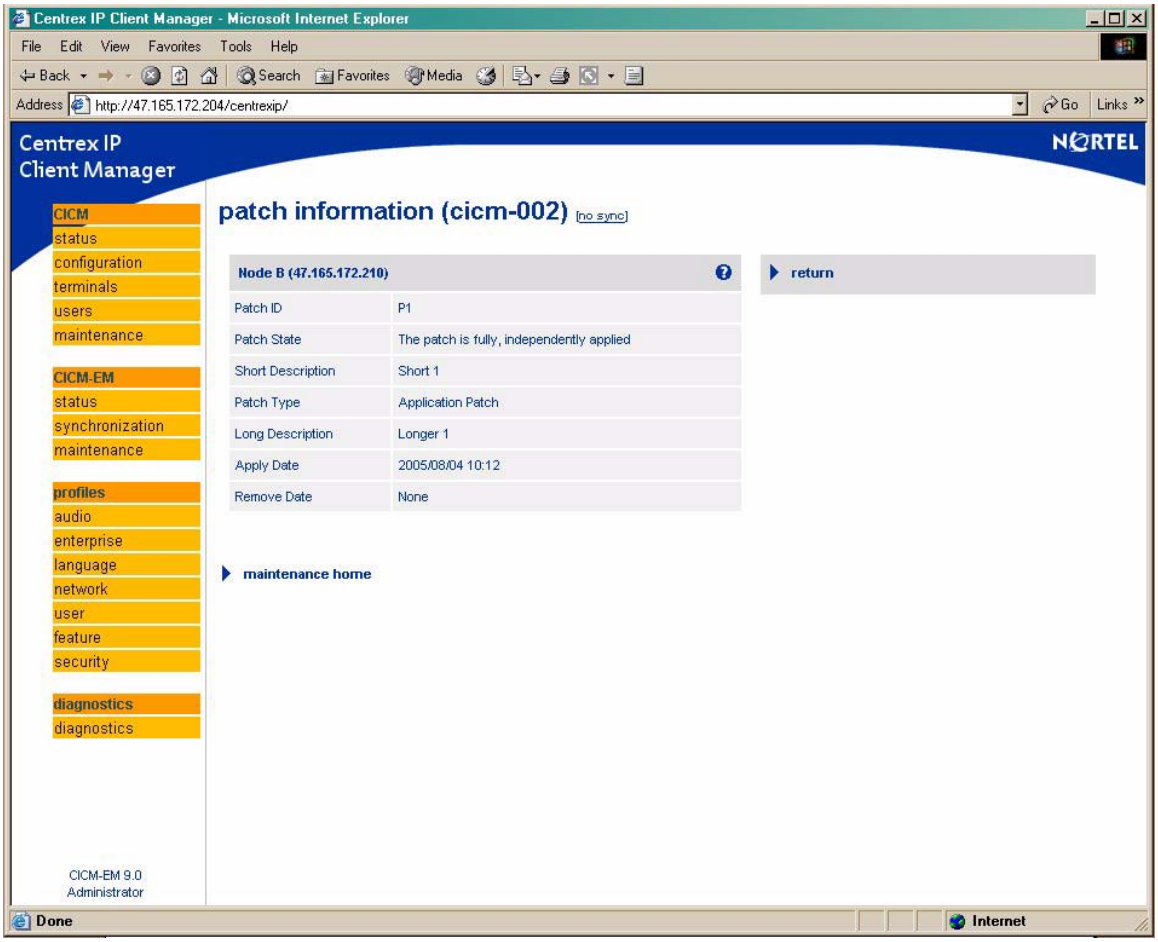

Figure 7 Patch Information Page

In addition, if a user wishes to view the patching history of a particular node, they can access the Patching History page via the ‘View Patching History’ link on the Patch Maintenance Page.

The Patching History page contains a list of all successful patching activity since the last Maintenance Release was applied. Details of patch applications, subsumations and removals will form this list.

A sample Patching History page is shown below.

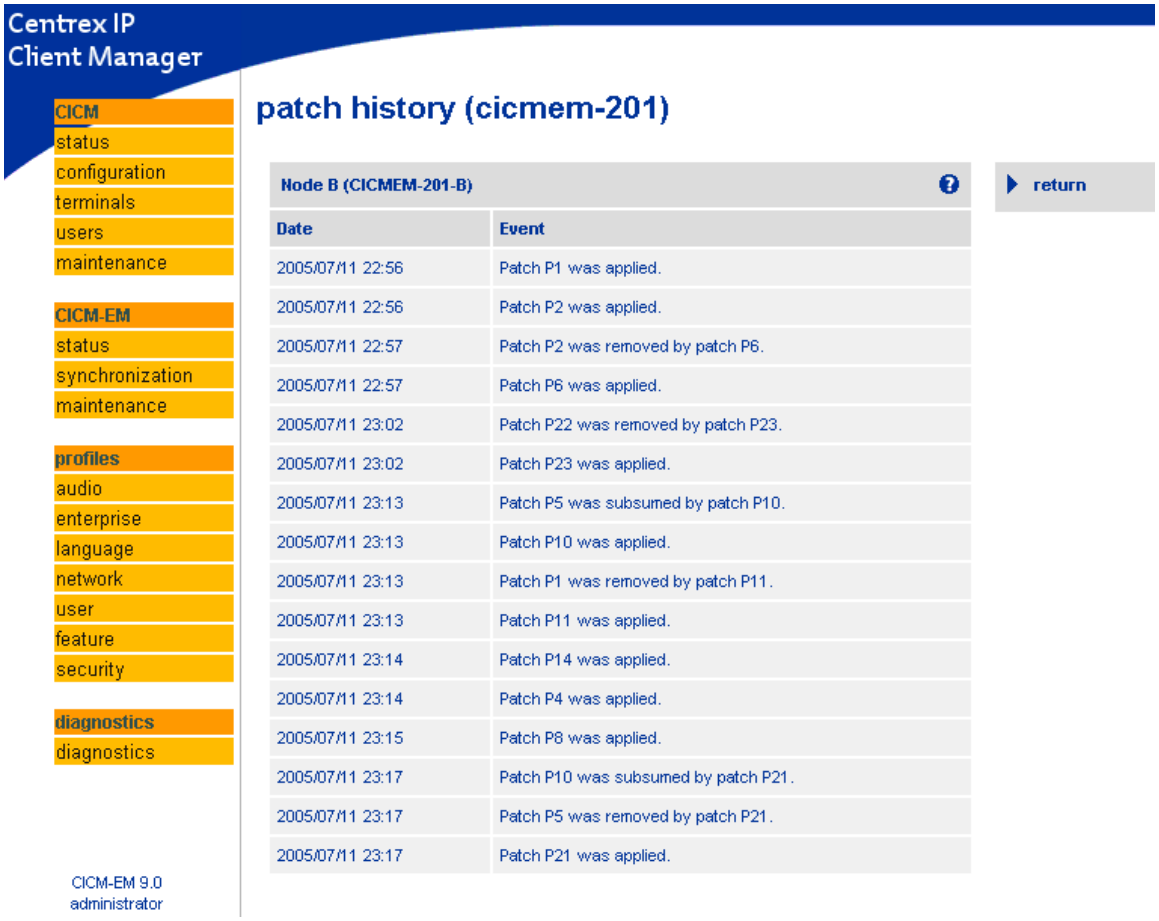

Figure 8 Patching History Page

When a Patch is not applied to the CICM or CICM-EM but it is in the removal list of a patch that was applied then the Patch History Page will still show the patch as removed (even though it may have never actually been applied). In this case the applied date field for the patch that was never applied will be “None”.

The possible states of patches are…

- The patch has been removed by another patch. A patch can not be re-applied to the system once it has been set to removed.
- The patch is fully, independently applied. The patch is independently applied and not subsumed by another. The ‘independence’ of a patch refers solely to subsumation i.e. whether it is contained in another patch or not. It does not have any bearing on the dependencies of the patch.
- The patch has been applied as a subsumation. This patch has been subsumed by another.

71.2.4 Maintenance Release Delivery and Application

Although the function of Maintenance Releases remains largely unchanged with the introduction of this feature, the addition of the Patching functionality will lead to changes in the deployment and application methods for installing an MR.

From SN09 Nortel GNPS will deploy Maintenance Releases to a customer in the form of a single MR file and a 128-bit MD5 checksum. The MR file and the checksum will be distributed separately in order to ensure the integrity of the Maintenance Release file.

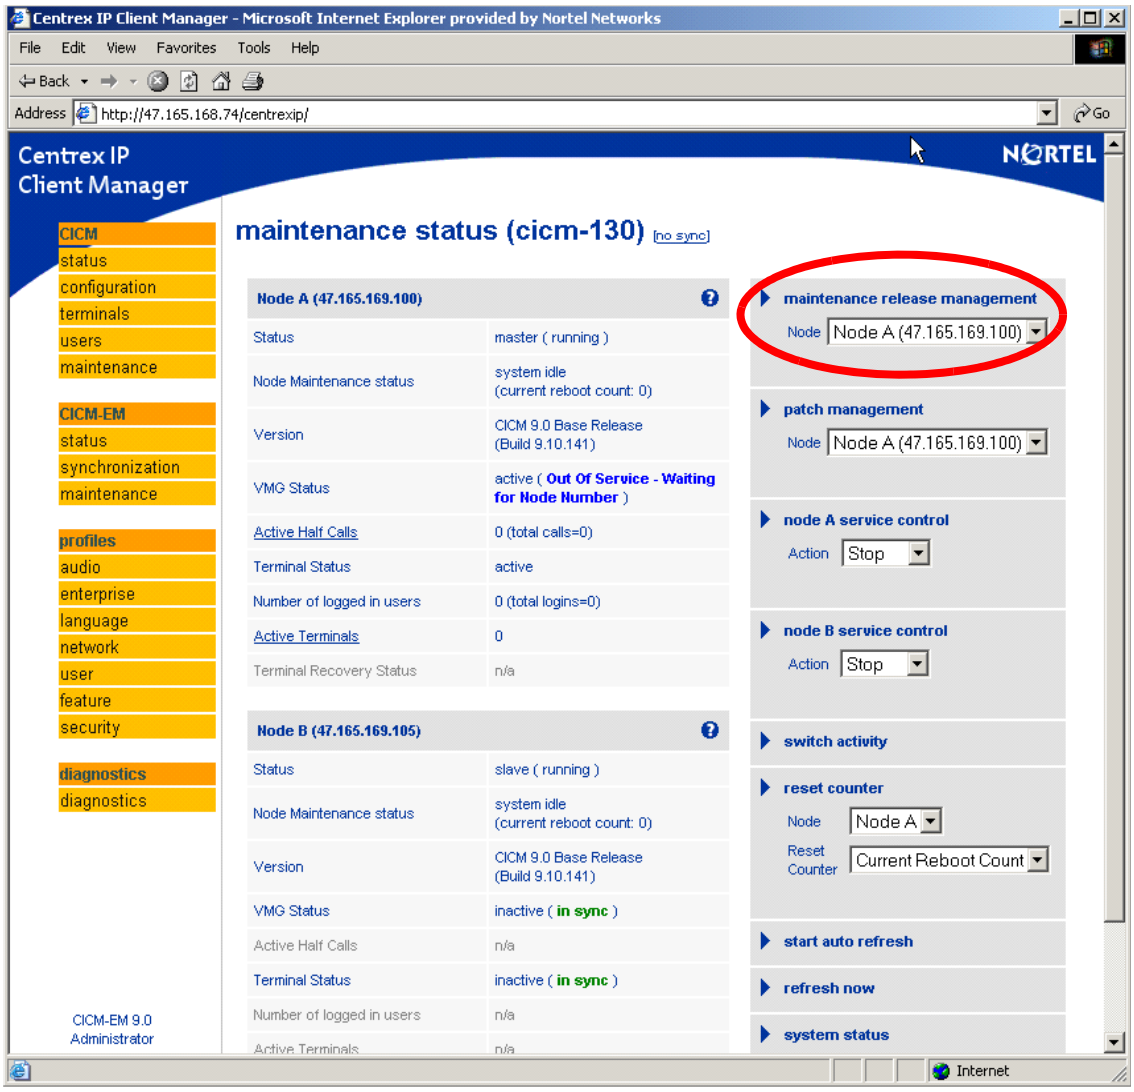

Figure 9 Maintenance Status Page

As with patches, the MR file will be delivered to the customer either via electronic transfer or on optical media. The MD5 checksum will be delivered to the customer either via e-mail or through it's publication on an externally accessible Nortel website.

Upon receiving the patch file, the customer will transfer the MR file into the Maintenance Release directory on the Master Element Manager (D:\CentrexIP\support\upgrades) via secure file transfer. Once there, the patch can be applied to any suitable node that is under the management of the CICM-EM.

From SN09, users will no longer be able to directly apply an MR from the main Maintenance Status page. Instead users will need to navigate to a new sub-Maintenance Release Management page from the main Maintenance Status page (see Figure 3).

The Maintenance Release Management page will display a table of all MRs that have been applied to this node along with their application time, date and status as shown below.

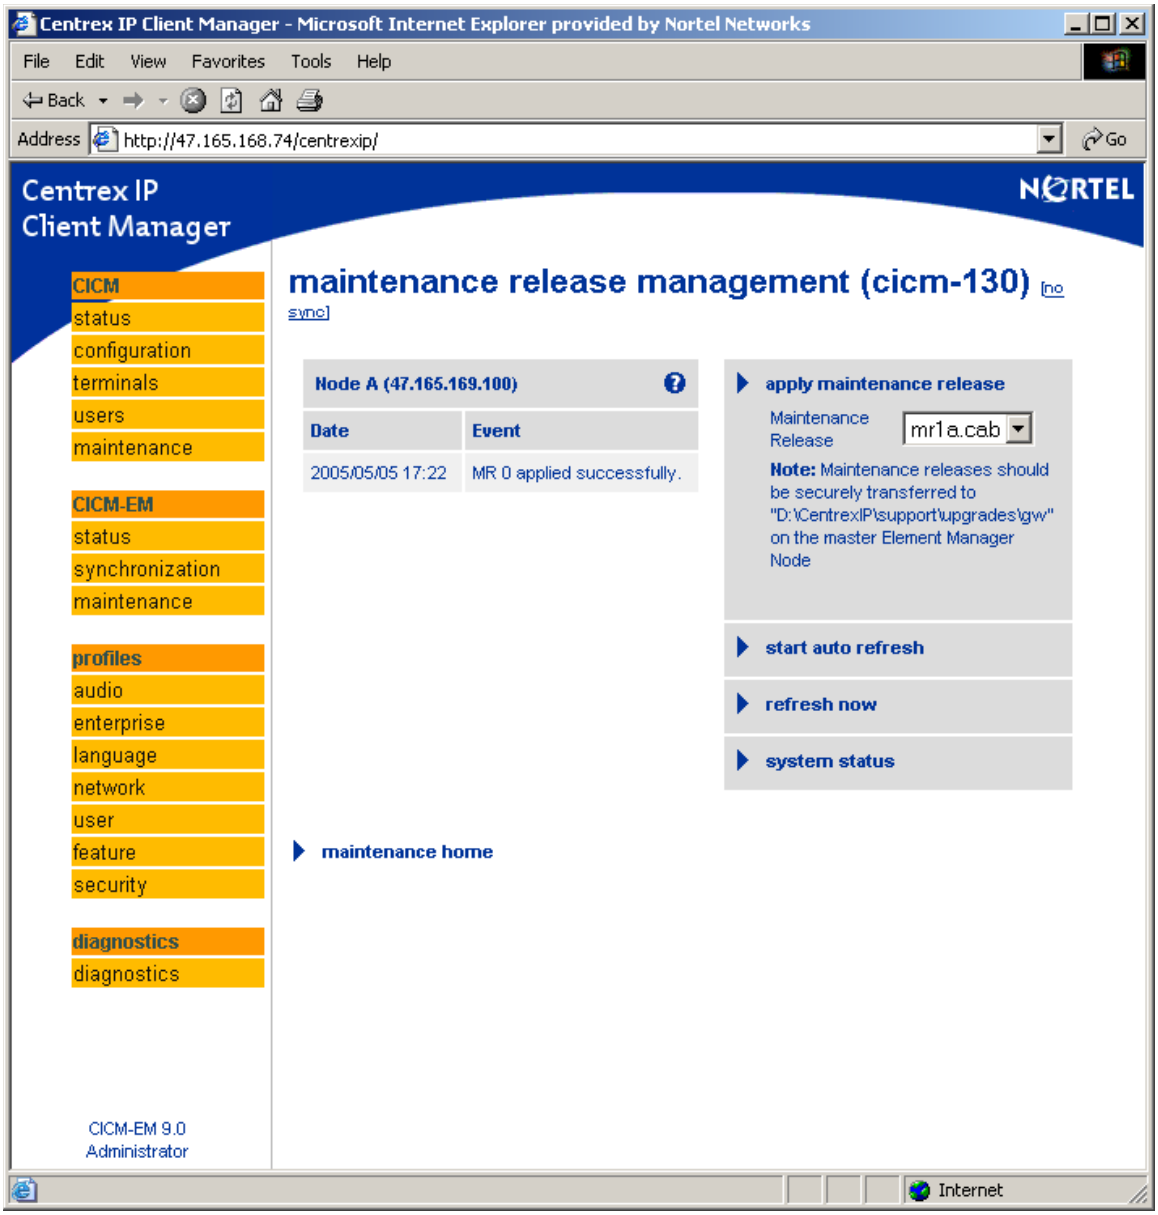

Figure 10 Maintenance Release Management Page

All MRs will have a status of ‘Applied’, since there is no way to remove an MR.

In addition, if a user wishes to view the patching history of a particular node, they can access the Patching History page via the ‘View Patching History’ link.

All Maintenance Releases copied into the MR directory on the Master Element Manager (D:\CentrexIP\support\upgrades) will be present in the ‘Select Patch’

dropdown menu. Once a user has selected the Maintenance Release to be applied from the dropdown list, they will be taken to the Maintenance Release Application page shown below.

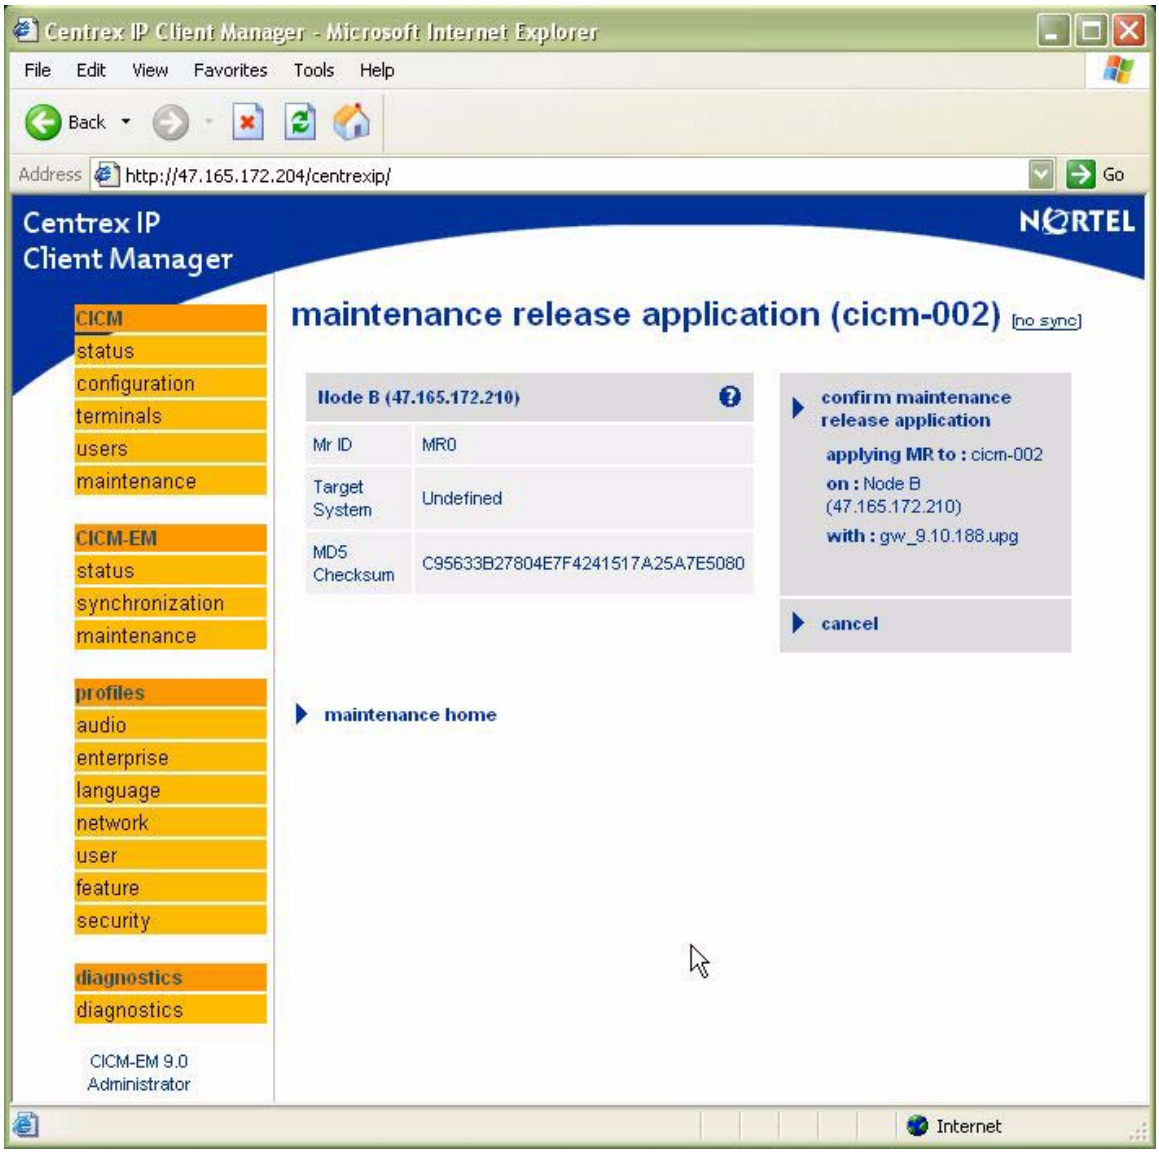

Figure 11 Maintenance Release Application Page

The Maintenance Release Application page will display all the details of the selected MR. If the selected node is of the correct system type and the MR has not already been installed, then the ‘Confirm MR Application’ link will be enabled in order to allow the application of the Maintenance Release. Otherwise the link will be disabled along with details of why the MR cannot be applied.

The Maintenance Release Application page will display the following information…

MR ID	The unique identifier for this MR
Checksum	The MD5 checksum of this patch file. The user should check that this checksum matches the checksum provided by Nortel for the Maintenance Release before applying the MR.
Target System	Indicates which type of node this patch can be applied to. This can be 'H248 CICM' or 'CICM EM'. If this patch is not valid for this node type it will be highlighted in Red.

It is the responsibility of the user to ensure that the checksum displayed for the patch file is identical to the checksum released for the patch by Nortel before applying the patch.

Once this is done, the Maintenance Release can be applied by clicking on the 'Confirm Patch Application' link. The user will then be taken to the Maintenance Status page where the status of the MR installation will be displayed. Assuming that the MR application is successful, it will appear on the Maintenance Release Management page with a status of 'Applied'.

If the MR installation fails for some reason, the MR will remain unapplied and will not be added to the list of applied MRs displayed on the Maintenance Release Maintenance page. As for patches, details concerning the failure will be generated in the debug log files.

In the event of a Maintenance Release installation failure, customers should contact the next level of Support.

71.2.5 Patch Version Control

The CICM and CICM-EM will follow an *independent* patching strategy. This means that as long each patch's rules for version control are satisfied…

- Customers can apply patches in any order they desire.
- Customers are not compelled to install *every* patch released by Nortel[1]

In order to allow this flexible independent patching strategy, whilst maintaining the overall sanity of the load content on the CICM and CICM-EM at all times, a patching version control system has been implemented.

This effectively defines what can and can not be applied to any particular CICM or CICM-EM. Overall load integrity and sanity is maintained by simply preventing incompatible content from being installed.

[1] Although customers should always follow the recommendation of Nortel CICM GNPS with regards to whether individual patches should be applied to in-service systems.

Patching Version Control is carried out by comparing records of what is currently installed on the system with information contained within each patch detailing its content and incompatibilities. If it is determined that the application of a particular patch would break one or more version control rules, then the 'Confirm Patch Application' link on the Patch Application page will be disabled, preventing the patch from being installed. In this instance, an the reason preventing the patch application will be given to the user so that corrective action can be taken.

Each patch will contain four lists defining its content, dependencies and conflicts as shown below.

Dependency List	This defines a list of patches that must be present on this node for this patch to be applied. If any of the patches contained within this list are not currently applied, then this patch cannot be applied.
Conflict List	This defines a list of patches which are incompatible with this patch. If any of the patches contained within this list are present on this node, then this patch cannot be applied. In addition, once applied, no patch contained within the conflict list of this patch can be applied without the removal of this patch first.
Subsumation list	This defines a list of all patches that are wholly subsumed (or contained) within in this patch. A patch can only subsume previously released patches. A patch which subsumes another patch contains fully the functionality of the previously released patch. Applying this patch will therefore also apply all the other patches contained within this list (if they are not already applied).
Removal list	This defines patches that will be removed by the application of this patch. Once applied, no patch contained within the removal list of this patch can be re-applied. Even if the patch has not been applied, the target system will not allow its application in the future.

When a patch is selected for application, the following simplified checks are carried out…

- The patch being installed must be of the correct type (CICM / CICM-EM) for the node it is about to be applied to.
- The build number of the target system must be that the patch is intended for.
- Each patch listed in the patch dependency list of the patch being installed must be presently installed on the system.
- None of the patches listed in the conflict list of the patch being installed may be presently installed on the system.
- None of the patches listed in the removal list of the patch being installed are present in the dependency lists of any of the currently applied patches.

- None of the patches listed in the content list of the patch being installed are present in the conflict or removal lists of any of the currently applied patches.

Only if ALL of the criteria above are met is the ‘Confirm Patch Application’ link enabled and the patch can be installed.

Once patch installation has been started ALL patches present in the Content list of the patch will be installed. Note that it is not possible to selectively install only some of the content of a patch.

Once a patch has been installed, the following changes are made to the patch content table on the node which the patch was applied to.

- All patches listed in the Content list of the patch applied are added to the list of applied patches with a status of 'Applied'.
- Any patches listed in the Removal list of the patch applied, that are present in the Applied Patch Table, will be changed to a status of 'Removed by <Patch ID>'.

In additional, the Dependency, Conflict, Content and Removal lists of the installed patch are stored on the node on which the patch was installed to assist with the version control checking of future patches.

71.2.6 Selective Service Start-up and Shutdown

An advantage the new patching functionality provides over the Maintenance Release functionality is that the application of a patch will not necessarily require a restart of the node that it is applied to, and may even be able to maintain service during its application.

Depending on the corrective content being delivered, the patch application software has the ability to apply a patch with either…

- A Full Node Outage (and loss of redundancy)
- A Partial Node Outage
- No Node Outage

The level of Service Outage required will always be defined by the patch. Patches that require a Full Service Outage will have the ‘Reboot Count’ field set to a non-zero number to indicate that as part of the patch installation the node will be rebooted and therefore be unavailable for a period.

Patches that have the ‘Reboot Count’ field set to nought will either require a Partial Service Outage or No Service Outage.

In the case of a patch that will need a partial service outage during installation, the exact level of the service outage that will be encountered, along with

exactly what service impact the customer can expect will be defined in the release notes of the patch by Nortel GNPS.

It is the responsibility of the craftsperson applying the patch to read and fully understand what impact the installation of a specific patch will have on an in-service system. And it is recommended that the supported patch installation procedure is always used when applying patched to in-service sites (see section 2.1.8 on Patching Procedure)

71.2.7 Patching Procedure

The following is the basic procedure for applying a patch to a pair of CICM nodes.

1 Take a system backup of the nodes being patched using the EM backup tool

2 SWACT call processing to Node A

3 Apply the patch to node B – should the patch installation fail, please stop and contact the next level of Support.

4 SWACT call processing to Node B

5 If possible verify the patch functionality and system sanity. If a problem is found, stop and contact the next level of Support.

6 Apply the patch to Node A – should the patch installation fail, please stop and contact the next level of Support.

7 SWACT call processing to Node A

8 If possible verify the patch functionality and system sanity. If a problem is found, stop and contact the next level of Support.

9 Patch installation is complete.

The following is the basic procedure for apply a patch to a pair of CICM-EM nodes.

1 Take a system backup of the nodes being patched using the EM backup tool

2 SWACT the CICM-EM if necessary so that Node A is the Master

3 Apply the patch to node B – should the patch installation fail, please stop and contact the next level of Support.

4 SWACT the CICM-EM so that Node A is the Master

5 If possible verify the patch functionality and system sanity. If a problem is found, stop and contact the next level of Support.

6 Apply the patch to Node A – should the patch installation fail, please stop and contact the next level of Support.

7 SWACT the CICM-EM so that Node A is the Master

8 If possible verify the patch functionality and system sanity. If a problem is found, stop and contact the next level of Support.

9 Patch installation is complete.

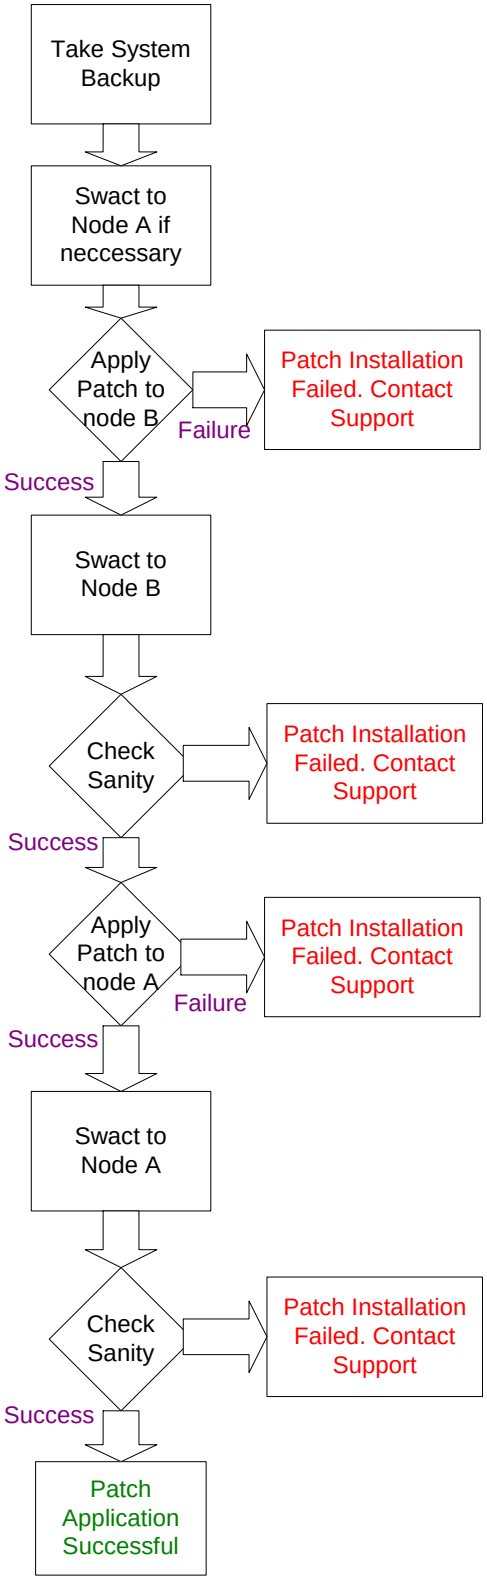

Figure 12 Patch Procedure

71.2.8 Maintenance Release Interaction with Patching

The web interface for Maintenance Release applications has been modified slightly. However from a functional point of view Maintenance Releases will be released and applied in exactly the same manner to the way they were before this feature was implemented.

The only minor exception is that from SN09 Maintenance Releases will be released with a checksum that should be checked to ensure integrity before application.

Maintenance Releases replace all application binaries on a system and apply all OS and Third Party Content up to a recognized and supported level (which is defined by the MR version).

An MR has no dependencies on the patch state of the target system before it is applied, since it is about to overwrite all content. Therefore an MR has no dependency or conflict lists and carries out no version checking against the current patch state before application. However, verification of the target type (CICM/CICM-EM) and upgrade path between build numbers is carried out.

Since a Maintenance Release overwrites all previous software versions, the record of all previous patches applied to this system will become irrelevant. For this reason, one impact of the application of a Maintenance Release is that it will erase the list of all currently applied patches. The content of this system is now defined by the MR version.

Normally the functionality of all the currently released patches will have been incorporated into a Maintenance Release. So although the record of applied patches has disappeared, the content of those patches will still be present on the system after the MR has been installed. A complete record of the content of a Maintenance Release, including all patches that it subsumes will be listed in its Release Notes of the Maintenance Release.

The current patch level of any system should be considered to be the MR version *plus* the patches listed in the applied patch list.

71.3 Hardware requirements

The SN09 Patching features introduce no new hardware dependencies or requirements.

The SN09 load is supported on:

- Motorola 5370 CPU cards
- Motorola 5385 CPU cards

71.4 Software Requirements or Dependencies

The Third Party Corrective Content Patching and Selective Binary Component Patching features are introduced in the SN09 CICM release. This load level must therefore be installed on any CICM-EM being used to apply a patch and on any CICM / CICM-EM that is being patched.

71.5 Limitations and restrictions

These features will only deploy Patches and Maintenance Releases built and released by Nortel CICM GNPS. Deployment of no other Patch or Maintenance Release files will be supported.

71.6 Interactions

This feature will modify the delivery of Maintenance Releases both by the inclusion of a Checksum for integrity checking and by the implementation of changes to the MR application web pages on the EM.

72: Functional description (FN): A00009378

72.1 Feature name and Feature ID

A00009378: LI Support of SIP Lines

72.2 Description

This feature provides the Call Data and Call Content interception functionality required to support Lawful Interception (LI) of calls originated by / terminated on SIP (Session Initiation Protocol) clients.

This document assumes that the reader is familiar with the United States Network Broadcast Delivery (USNBD) functionality as described in [1] and [2]. Therefore, only the functional areas that are modified or unique to SIP Line surveillances are covered by the subsequent sections.

72.2.1 Configuration and Administration Procedures

The list of procedures that can be performed by USNBD administrators and USNBD users are the following. The procedures with SIP Line specific behavior are highlighted in *italics*.

- Executing pre-provisioning requirements for USNBD
- *Configuring bearer channel tandeming (BCT) on an MS 200 series (AMS)*
- Activating software optionality control (SOC) option NBD00003
- Activating BCT
- Activating USNBD office-wide parameters
- Adding an agency
- Adding USNBD users
- *Creating call content resources (CCR*)
- Creating a call data channel (CDC)
- *Adding a surveillance*
- Listing a surveillance
- Associating a CDC with a surveillance
- Associating a CCR with a surveillance
- Activating a surveillance
- Deactivating a surveillance
- Taking down a surveillance
- Deleting a CCR

- Deleting a CDC
- Deleting USNBD agencies
- Deleting USNBD users
- Deactivating BCT
- Deactivating SOC option NBD00003
- Accessing LI-Specific operational measurements

72.2.1.1 Configuring BCT on AMS

A single SIP Line surveillance can result in multiple active surveillance sessions, since a SIP line agent supports multiple call appearances. This needs to be accounted for when enabling Lawful Intercept parameter on an Application Media Server (AMS). In other words, there should be sufficient AMSs / ports configured to support BCT on all targets that can be under Call Content surveillances

The required number of CCRs can be calculated using the formula in figure 1.

The total number of ports can be calculated by simply multiplying the required number of CCRs by the number of ports per CCR.

Figure 1 CCR Calculation

CCRs Required = (**A1** * **B1**) + (**A2** * **B2** * **m**)) * **C**

Where:

A1 Total number of non SIP Line surveillance expected on the switch

A2 Total number of SIP Line surveillances expected

B1 Percentage of A1 that requires call content delivery

B2 Percentage of A2 that requires call content delivery

C Average number of call content resources (CCR) for each surveillance. The maximum is 5.

m Maximum number of SIP Line call appearances (per line) that can be monitored simultaneously for call content. This is limited by the number of CCRs that can be assigned against each surveillance.

72.2.1.2 Creating CCRs

The SIP lines are not supported as CCR Call Content Channels (CCCs). In other words, the CR must use a line with a 10 digit DN, which is a "single party line" meeting the existing requirements with respect to the line class code and assigned options.

72.2.1.3 Adding a Surveillance

The SIP Line surveillances are provisioned against the line DN. When the surveillance is activated, multiple calls originating and terminating on the target are monitored.

If the call content is to be monitored, the number of calls that can be monitored for call content is limited by the number of CCRs that is assigned to the surveillance. A maximum of 5 CCRs can be assigned to each surveillance.

If both call data and call content monitoring are enabled for a given surveillance, the CDC messages are generated, even in the scenario where call content is not monitored due to CR unavailability.

72.2.2 Call Content Monitoring

72.2.2.1 Multi-Media Monitoring

SIP Lines support multi-media capabilities, which include video and Information Services.

This feature only supports monitoring of speech, 3.1 KHz audio, 64 Kb/s restricted and unrestricted data, and 64Kb/s unrestricted data rate adapted from 56Kb/s.

In other words, video and Information Services content is not monitored as FCC currently does not mandate monitoring of data for information services.

72.2.2.2 Private Network Interception (PNI)

Private Network Interception (PNI) provide the ability to intercept the call content of private network calls. The PNI also provides Internet Transparency (ITRANS) by allowing the USNBD user to specify if call content monitoring for private network should be enabled, when the media gateways of both call agents are behind the same intra-domain Network Address Translator (NAT).

The PNI can be enabled on individual surveillances. This capability is provided for surveillances associated with SIP Lines. All calls originated by or terminated on a SIP Line target is examined to determine the call content should be monitored. If the call content is not monitored as a result of PNI not being enabled, a "CCUnavailabe" CDC message is generated.

72.2.2.3 REFER Support

The call content monitoring associated with SIP REFER method is best described using the example scenarios listed in the subsequent sections. The monitored party (target) is identified with an asterisk.

All scenarios are based on party 'A' REFERing (party B) to C after A and B has established a call. Each scenario below examines the need to define multiple CCRs for a given surveillance depending on which agents are under being monitored.

72.2.2.3.1 Call Transfer to Target

Scenario:

1. A Calls B and establishes A<->B session
2. A REFER to C*, causing B<->C* session to be established. A drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A<->C*
- B<->C*

Only a single call (involving C*) needs to be monitored at a given time. Therefore, only one CCR needs to be associated with the C* surveillance.

72.2.2.3.2 Call Transfer by Associate to non-Target

Scenario:

1. A Calls B* and establishes A<->B* session
2. A REFER to C, causing B*<->C session to be established. A drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A<->B* (initial call)
- B*<->C

Only a single call (involving B*) needs to be monitored at a given time. Therefore, only one CCR needs to be associated with the B* surveillance.

72.2.2.3.3 Call Transfer by Associate to Target

Scenario:

1. A Calls B* and establishes A<->B* session

2. A REFER to C*, causing B*<->C* session to be established. A drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A<->B* (initial call)
- A<->C* (interim call)
- B*<->C*

Only a single call per subject needs to be monitored at a given time. Therefore, only one CCR needs to be associated with each B* and C* surveillances.

72.2.2.3.4 Call Transfer by Target to non-Target (1 Original Target)

Scenario:

1. A* Calls B and establishes A*<->B session
2. A* REFER to C, causing B<->C session to be established. A* drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A*<->B (initial call)
- A*<->C (interim call)

Two calls involving A* need to be monitored at a given time. Therefore, 2 CCRs need to be associated with A* surveillance. Otherwise, the A*<->C call content is not monitored.

72.2.2.3.5 Call Transfer by Target to Target (1 Original Target)

Scenario:

1. A* Calls B and establishes A*<->B session
2. A* REFER to C*, causing B<->C* session to be established. A* drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A*<->B (initial call)
- A*<->C* (interim call)
- B<->C*

Two calls involving A* need to be monitored at a given time. Therefore, 2 CCRs need to be associated with A* surveillance. Otherwise, the A*<->C* call content is not monitored.

72.2.2.3.6 Call Transfer by Target to non-Target (2 Original Targets)

Scenario:

1. A* Calls B* and establishes A*<->B* session
2. A* REFER to C, causing B*<->C session to be established. A* drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A*<->B* (initial call)
- A*<->C (interim call)
- B*<->C

Two calls involving A* need to be monitored at a given time. Therefore, 2 CCRs need to be associated with A* surveillance. Otherwise, the A*<->C call content is not monitored.

72.2.2.3.7 Call Transfer by Target to Target (2 Original Targets)

Scenario:

1. A* Calls B* and establishes A*<->B* session
2. A* REFER to C*, causing B*<->C* session to be established. A* drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A*<->B* (initial call)
- A*<->C* (interim call)
- B*<->C*

Two calls involving A* need to be monitored at a given time. Therefore, 2 CCRs need to be associated with A* surveillance. Otherwise, the A*<->C call content is not monitored.

72.2.2.4 Support for SIP 4XX Responses

To be completed after base prototype is completed.

72.2.3 Call Data Monitoring

72.2.3.1 REFER Support

The call data monitoring associated with SIP REFER method is best described using the examples listed in the subsequent sections. The monitored party

(target) is identified with an asterisk. The legend below explains other symbols and notations being used.

Table 6: Legend

Symbol	Explanation	Example
A, B, C	DNs of the agents involved in the call	CalledPartyIdentity - A / Pa
Nx	Sequence Number	CallIdentity - SequenceNo : N1
Pa, Pb, Pc	Ports of the agents involved in the call	CalledPartyIdentity - C / Pc

Note: For simplicity, the examples do not include the CCOpen and CCClose Call Data messages, even though they are being generated for the scenarios presented below.

72.2.3.1.1 Call Transfer to Target

Scenario:

1. A Calls B and establishes A<->B session
2. A REFER to C*, causing B<->C* session to be established. A drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A<->C*
- B<->C*

CDC Messages Generated as a result of REFER:

Table 7: CDC MEssages - Scenario 1

Message	Parameter Attribute Values	Notes
TerminationAttempt	CallIdentity - SequenceNo : N1	A to C* call
	CallingPartyIdentidy - A / Pa	
	CalledPartyIdentity - C / Pc	
Connect	CallIdentity - SequenceNo : N1	
	ConnectPartyIdentities - A / Pa, C / Pc	
Answer	CallIdentity - SequenceNo : N1	
	AsweringPartyIdentity - C / Pc	
Disconnect	CallIdentity - SequenceNo : N1	
Release	CallIdentity - SequenceNo : N1	
TerminationAttempt	CallIdentity - SequenceNo : N2	B to C* call
	CallingPartyIdentidy - B / Pb	
	CalledPartyIdentity - C / Pc	
Connect	CallIdentity - SequenceNo : N2	
	ConnectPartyIdentities - B / Pc, C / Pc	
Answer	CallIdentity - SequenceNo : N2	
	AsweringPartyIdentity - C / Pc	

72.2.3.1.2 Call Transfer by Associate to non-Target

Scenario:

1. A Calls B* and establishes A<->B* session
2. A REFER to C, causing B*<->C session to be established. A drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A<->B* (initial call)
- B*<->C

CDC Messages Generated as a result of REFER:

Table 8: CDC MEssages - Scenario 2

Message	Parameter Attribute Values	Notes
Disconnect	CallIdentity - SequenceNo : N1	A to B* call
Origination	CallIdentity - SequenceNo : N2	B* to C call
	CallingPartyIdentidy - B / Pb	
	CalledPartyIdentity - C / Pc	
	Input - UserInput: <dialed digits>	
Connect	CallIdentity - SequenceNo : N2	
	ConnectPartyIdentities - B / Pb, C / Pc	
Answer	CallIdentity - SequenceNo : N2	
	AsweringPartyIdentity - C / Pc	

72.2.3.1.3 Call Transfer by Associate to Target

Scenario:

1. A Calls B* and establishes A<->B* session
2. A REFER to C*, causing B*<->C* session to be established. A drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A<->B* (initial call)
- A<->C* (interim call)
- B*<->C*

CDC Messages Generated as a result of REFER:

Table 9: CDC MEssages - Scenario 3

Message	Parameter Attribute Values	Notes
TerminationAttempt	CallIdentity - SequenceNo : N2	A to C* call
	CallingPartyIdentidy - A / Pa	
	CalledPartyIdentity - C / Pc	
Connect	CallIdentity - SequenceNo : N2	
	ConnectPartyIdentities - A / Pa, C / Pc	
Answer	CallIdentity - SequenceNo : N2	
	AsweringPartyIdentity - C / Pc	
Disconnect	CallIdentity - SequenceNo : N1	HOLD A to B* call
Disconnect	CallIdentity - SequenceNo : N2	A to C* call Released
Release	CallIdentity - SequenceNo : N2	
Origination	CallIdentity - SequenceNo : N3	B* to C* call
	CallingPartyIdentidy - B / Pb	
	CalledPartyIdentity - C / Pc	
	Input - UserInput: <dialed digits >	
Connect	CallIdentity - SequenceNo : N3	
	ConnectPartyIdentities - B / Pb, C / Pc	
TerminationAttempt	CallIdentity - SequenceNo : N3	
	CallingPartyIdentidy - B / Pb	
	CalledPartyIdentity - C / Pc	
Connect	CallIdentity - SequenceNo : N3	
	ConnectPartyIdentities - B / Pc, C / Pc	
Answer	CallIdentity - SequenceNo : N3	
	AsweringPartyIdentity - C / Pc	
Release	CallIdentity - SequenceNo : N1	A to B* call released

72.2.3.1.4 Call Transfer by Target to non-Target (1 Original Target)

Scenario:

1. A* Calls B and establishes A*<->B session
2. A* REFER to C, causing B<->C session to be established. A* drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A*<->B (initial call)
- A*<->C (interim call)

CDC message details to be completed after base prototype is completed.

72.2.3.1.5 Call Transfer by Target to Target (1 Original Target)

Scenario:

1. A* Calls B and establishes A*<->B session
2. A* REFER to C, causing B<->C* session to be established. A* drops out and is no longer part of the call.

In this scenario, two calls are monitored;

- A*<->B (initial call)
- A*<->C (interim call)

CDC message details to be completed after base prototype is completed.

72.2.3.1.6 Call Transfer by Target to non-Target (2 Original Targets)

Scenario:

1. A* Calls B* and establishes A*<->B* session
2. A* REFER to C, causing B*<->C session to be established. A* drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A*<->B* (initial call)
- A*<->C (interim call)
- B*<->C

CDC message details to be completed after base prototype is completed.

72.2.3.1.7 Call Transfer by Target to Target (2 Original Targets)

1. A* Calls B* and establishes A*<->B* session
2. A* REFER to C*, causing B*<->C * session to be established. A* drops out and is no longer part of the call.

In this scenario, three calls are monitored;

- A*<->B* (initial call)
- A*<->C (interim call)
- B*<->C

CDC message details to be completed after base prototype is completed.

72.2.3.2 Support for SIP 4XX Responses

To be completed after base prototype is completed.

72.3 Hardware Requirements or Dependencies

SIP Line LI works with the base hardware used by USNBD. In other words, no SIP Line specific hardware is needed for monitoring SIP Line calls.

72.4 Software Requirements or Dependencies

This feature depends on the functionality provided by the following SIP Line features.

- A00007547 - SIP Lines Core Call Processing Support
- A00008234 - GWC Development for Support of CS2K SIP Lines
- A00008556 - SIP Core OAMP support
- A00009239 - SIP Lines Client Services Support

72.5 Limitations and restrictions

- A maximum of 5 basic calls per SIP Line surveillance can be simultaneously monitored for call content
- The maximum number of surveillances that can be provisioned is 1024. This can be reduced based on the number of provisioned CCRs, if the call content is to be monitored.
- The maximum number of surveillances that can be active is 1024.
- Video and Information Services media monitoring is not supported.
- SIP line DNs are not supported as dedicated CCR Call Content Channels.

72.6 Interactions

This feature provides the LI capability where SIP Lines interworks with non-SIP agents. This includes the following scenarios.

- Only the SIP Line is under surveillance
- Only the non-SIP Line agent is under surveillance
- Both SIP and non-SIP Line agents are under surveillance

The LI follow capability and replacement party monitoring (MRP) are supported in the following contexts

- Only the SIP-LInes are involved in the call
- The SIP-Line agents interwork with the non-SIP Line agents

Table 10, "SN09 SIP Line Feature Interactions," on page 629 lists the LI support of SIP Line features for each of the following monitoring categories.

- Subject: A status of Y indicates that monitoring of subject's call leg is supported if the feature is present on the call leg. A status of N indicates that USNBD does not monitor the call leg if the feature is present on the subject's call leg.
- MRP: A status of Y indicates that monitoring of Monitored Replacement Party's (MRP) call leg is supported if the feature is present on the call leg. A status of N indicates that, USNBD does not monitor the call leg if the feature is present in the MRP's call leg.
- Redirect: A status of Y indicates that the feature supports redirection and an MRP is provided. A status of N indicates that an MRP is not provided, if the call is redirected.

The status of Subject / MRP / Redirect can be augmented with one of the following notes to clarify any special handling.

a. Valid only for CENTREX

b. Monitoring will end if the feature is activated on the call leg

c. The LEA is provided with the required information, but the Release message includes the "non-monitored feature" Reason parameter.

d. Monitoring ends if bridging by other MADN members occurs.

Table 10: SN09 SIP Line Feature Interactions

Feature	Description	Subject	MRP	Redirect
3WC	Three-Way call	Y	Y	Y (a.)

73: Functional description (FN): A00009417

73.1 Feature name and Feature ID

Cold Cache Recovery. Feature Number A00009417

73.2 Description

This feature adds the ability for a standby Session Manager to be fully synchronized with the provisioning manager when the Session Manager is set to active.

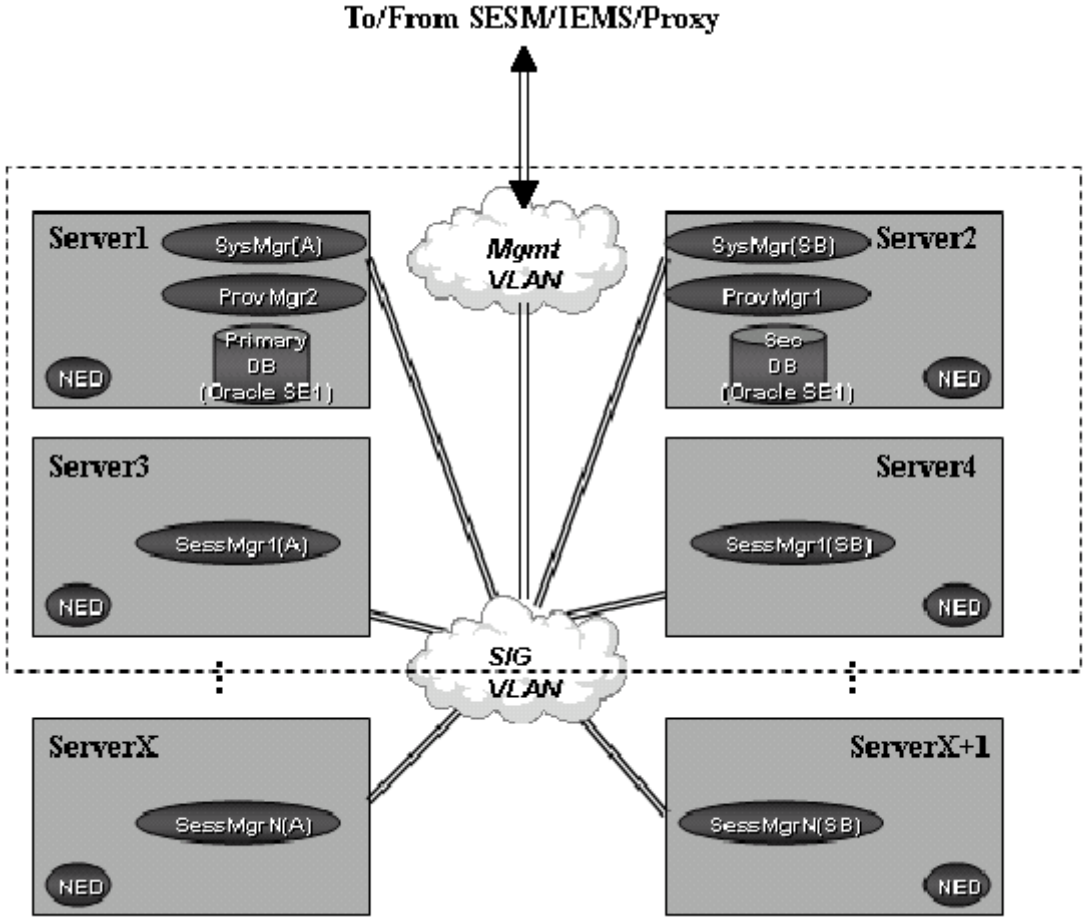
This feature is divided into two separate tasks. First, the Session Manager's In Memory Database (IMDB) tables must be synchronized with the data maintained by the provisioning manager. Synchronization between the Session Manager and the Provisioning Server is presently implemented by the Data Synchronization software. Unfortunately, MCP Data Synchronization relies upon the SIP NOTIFY message, and standby Session Managers are not able to receive and process NOTIFY messages since their Service Address (i.e. SIP listening address) is not enabled until the Session Manager goes active. This feature will convert the synchronization of data from the NOTIFY method to the Event Framework which does not require the Service Address to be enabled.

Secondly, the Session Manager presently employes a "lazy cache" method to populate the Subscriber tables. This lazy cache method involves not requesting Subscriber data until it is IMDB required by IPTel for session processing (call, IM, collaboration, etc.) processing. Features such as CallP Checkpointing require that the Subscriber data be known at the time the Session Manager goes from standby to active. This feature will now load and maintain the Subscriber IMDB tables while the Session Manager is in standby mode.

73.3 Hardware Requirements or Dependencies

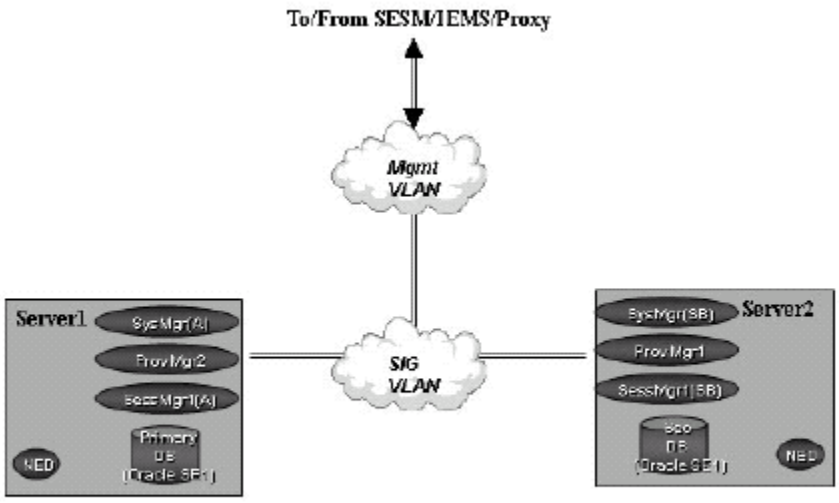
The diagram below represents the MSM configuration for 35000 subscribers. In this diagram, Server 3 and 4 represent an active/standby pair for Session manager instance 1 (SessMgr1). Server 3 is the active instance signified by the (A) and Server 4 represents the standby instance signified by (SB).

Figure 1: 35000 Subscriber System



The following diagram represents the configuration for 15000 subscribers. In this diagram, SessMgr1(SB) represents the standby instance for SessMgr1(A), the active instance.

Figure 2: 15000 Subscriber System



The diagrams above do not represent the only configuration possible.

73.4 Software Requirements or Dependencies

This feature is part of the MCP 9.0 release.

73.5 Limitations and restrictions

The time required for a Session Manager to start will be increased due to the fact that all Subscribers will be loaded at initialization time.

73.6 Interactions

This feature will speed up call processing in that IPTel will no longer be required to query the database for a new subscriber. All subscribers will be loaded into the Subscriber IMDB table prior to any session activity.

This feature will make extensive use of the Event Framework mechanism. The Event Framework uses a TCP socket monitored by a UDP ping (Perfect Channel). The Event Framework allows one MCP Network Element (NE) to send an event to another MCP NE.

73.7 Glossary

Term	Description
IMDB	In Memory Database
SIP	Session Initiation Protocol
IPTel	The MCP procession entity for SIP sessions
NOTIFY	A SIP message used to notify a SIP server of some activity

74: Functional description (FN): A00009418

74.1 Feature name and Feature ID

MCS as a 3G Application Server, activity A00009418

74.2 Introduction: 3GPP Network Overview

The 3GPP Application Server (AS) is one of the nodes of the IP Multimedia Core Network Subsystem (IMS) of the Core Network (CN) infrastructure in a 3GPP PLMN.

The intent of the IMS, is to enable the convergence of, and access to, voice, video, messaging, data and web-based technologies for the wireless user, and to combine the growth of the Internet with the growth in mobile communications.

The role of the AS in the IMS is to offer value added IP Multimedia (IM) services by hosting and executing network and user level services.

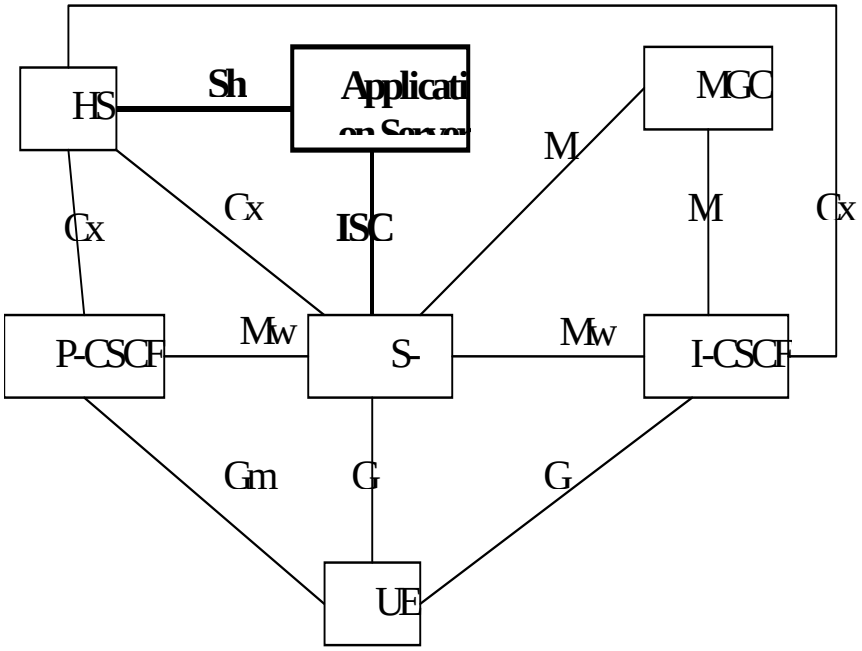


Figure 1 IMS Elements and their interworking interfaces

In a 3GPP network, the AS only becomes involved in a dialogue when the S-CSCF inserts it. Furthermore, an AS does not interact directly with the UE, instead it always interacts directly with the S-CSCF. The interface used for this interaction is the ISC interface.

The 3GPP specifications define the ISC interface as being compliant with IETF SIP (RFC 3261), but with additional support for 3GPP extensions (TS 23.228).

The S-CSCF inserts an AS into a dialogue mainly due to user provisioning data. When the S-CSCF insert the AS, it does so in a manner which indicates to the AS that it should execute either originating or terminating subscriber services, but never both simultaneously. This AS 3GPP requirement is referred to as “running in a half call model”.

The AS implications of running in a half call model are:

- only originating (or terminating) services are executed as requested by the S-CSCF
- completion of service execution results in the AS forwarding the dialogue back to the requesting S-CSCF

Subscriber registrations also occur on the AS without direct interaction with the UE. These are known as 3rd party registrations, and they originate from the S-CSCF. In other words, the UE originates registration requests to the S-CSCF and as a result, the S-CSCF originates a separate registration request to the AS on behalf of the UE. Furthermore, the S-CSCF places itself as the UE’s contact address in this separate request.

The S-CSCF also takes over the responsibility of performing subscriber authorizations. Therefore, the AS does not need to (and it must not) perform this task.

In a 3GPP network, the subscriber data is maintained in a single database: the HSS. The AS and the various CSCF nodes make use of this database when they require access to subscriber data. The interface used by the AS to interact with the HSS is the Sh interface.

The 3GPP specifications define the Sh interface as an IETF vendor specific Diameter application (TS 29.239).

For in-depth information about the 3GPP AS, CSCF nodes, and the various IMS interfaces and procedures, please consult TS 23.218, TS 23.228, and TS 24.229

74.3 Feature Description

The purpose of this feature is to modify the release 9.0 MCS Standalone Session Manager network element to function as a 3GPP AS with restrictions/ limitations. The resulting product will be referred to as MCS R6 AS.

The capabilities of the MCS R6 AS will be:

- Support for the Nortel 3GPP PC Client
- Support for the ISC interface to interact with the Nortel 3.0 S-CSCF
  - — Support for P-Charging-Vector ICID parameter
  - — Support for the orig-dialog-id tag in the route header
  - — Support for the nt_info tag in the route header
  - — Support for the P-Called-Party-ID header for call forwarding
  - — Support for the Request-Dispositon no-fork tag
- Support for terminating ½ call model subscriber services
  - — Call Screening and Routing
  - — AdHoc Conference
  - — MeetMe conference
  - — Hold (remote & local)
  - — Direct and Consultative Transfers
  - — Redirects
  - — Calling Line ID (note that only the terminating side of this service is supported)
  - — Instant Messaging
- 3rd Party registrations via the REGISTER method
- Support for a new IPDR record unit to collect the ICID
- Support for acting as a proxy between the S-CSCF and the MAS
- Support for AC PRI GW originations with restrictions
- Support for AC PRI GW terminations with restrictions
- 80K BHCA per node (weighted-use services model)

The restrictions and limitations of the MCS R6 AS are:

- Any subscriber service not explicitly mentioned in the previous list is not supported (ie. Presence is not supported, Callpark is not supported, etc…).
- RFC 2833 is the only supported method for DTMF
- No support for originating ½ call model subscriber services

- No support for originating or terminating full call model services (a non-compliant mode for a 3GPP AS)
- The MCS R6 AS will not support the Sh interface. Therefore, the AS will not be able to query an HSS for subscriber data.
- The MCS R6 AS will only be supported in the same hardware configuration as the 9.0 Standalone MCS.
- The MCS R6 AS will continue to use the same OAM system as the Release 9.0 Standalone MCS.
- The MCS R6 AS will need to be deployed in the same MCS network element topology as the 9.0 Standalone MCS, with the exception that Media Portal, IPCM and Gatekeeper are not supported (see the 9.0 MCS OAM System Architecture Document).
- Voicemail service is not supported on this release due to a sequential routing restriction existing on the S-CSCF.
- Sequential and Simultaneous routing is not supported on this release due to a sequential routing restriction existing on the S-CSCF.
- If multiple registrations exist for a user, only the most recent registration will be “rung” when such a user is on the receiving end of a call.
- The MCS R6 AS will only interface with the MAS (using RFC 3261) and the S-CSCF (using 3GPP ISC). Interacting with any other node is not supported. In other words: CS1K, CS2K, WCM, MediaPortal, IPCM, H.323 gatekeeper, etc… are not supported in this release.
- PSTN originations (through the AC PRI GW) are supported with the following restrictions (note: the following restrictions apply solely to PSTN originations, unless otherwise noted!!):
  - — R6 AS to accept calls coming from AC PRI GW, in the same way the Standalone MCS SessionMgr does today.
  - — If orig and term subscribers received in INVITE from GW match MCS subscribers, both orig and term services will run before the S-CSCF is involved in the call
  - — R6 AS services will execute twice per call: the first time will be when the AS receives the call from the GW, and the second time when the S-CSCF inserts the AS into the call.
  - — To the R6 AS, the call from the GW is one call, and the call from the S-CSCF is a separate and different call.
  - — R6 AS to add a route header (with orig parm) to INVITE it sends to S-CSCF. The information in that route header will be the information which was received (during registration of the final destination subscriber) in the contact header of the REGISTER message.

- R6 AS to add P-Charging-Vector to INVITE it sends to S-CSCF. The header will contain a newly generated ICID, and a R6 AS wide value in the IOI parameter.
- If no contact info is available for final destination subscriber, the behaviour will be identical to that of the standalone MCS ApplicationServer.
- No UPDATE message support due to the lack of support for this message in the AudioCodes PRI GW.
- User's who re-route calls (through CPL) to specific routes with IP Addresses will cause the R6 AS to contact those routes without involving the S-CSCF.
- Calls forwarded back to a PSTN number will route back to the PSTN without ever involving the S-CSCF
- Privacy on PSTN originations will be honored at the AS. The R6 AS considers the S-CSCF as a "privacy trusted" node, therefore the AS will not anonymize headers. However, the S-CSCF does not support any privacy setting other than "privacy: none", therefore the network cannot claim to support privacy.
- R6 AS can only route calls to registered MCS subscribers. If the subscriber is not an MCS subscriber, the call will be rejected with a 404 response. If the terminating subscriber is not registered, the call will be rejected with a 480 response. However, if an MCS subscriber is not registered, but has forwarded all calls to a routable destination, the call will complete to the new destination.
- If subscriber receiving call is forwarded to another subscriber (and so on), all involved subscriber's services will execute before S-CSCF is involved in the call.
- If subscriber is not forwarded and is registered, the INVITE will go to the registered contact address. Since in this network, the S-CSCF performs 3rdParty registrations, this registered contact address for all subscribers is expected to be the address of a S-CSCF. However, if for some reason, the registered contact address is not the address of a S-CSCF, the AS will still route the call to such addresses.

- PSTN terminations (through the AC PRI GW) are supported with the following restrictions (note: the following restrictions apply solely to PSTN terminations, unless otherwise noted!!):
  - R6 AS will route calls to a AC PRI GW as long as destination does not match a subscriber nor a MAS pooled resource alias, but it does match a telephony translation entry which contains a GW route.
  - When running subscriber term services and if the subscriber is requesting to be forwarded to the PSTN, the AS will route the call back to the S-CSCF with the forwarded to PSTN number as the destination.

It will be up to the S-CSCF at this point to find an AS which can route to that PSTN destination, and to send an INVITE to that AS with the proper nt_info parm.

— AS will use sip extension header(s) to transport information between appservers, if the S-CSCF happens to be a node in the middle, it shall proxy the headers unmodified. If this condition is not met, calls will most certainly fail.

— AS to filter 3GPP headers from GW if necessary.

— AS to filter route header from GW if necessary.

— On 200 OK sent towards the S-CSCF, the AS will insert (on behalf of the GW) an R6 AS wide value in the term IOI parameter of the p-charging-vector.

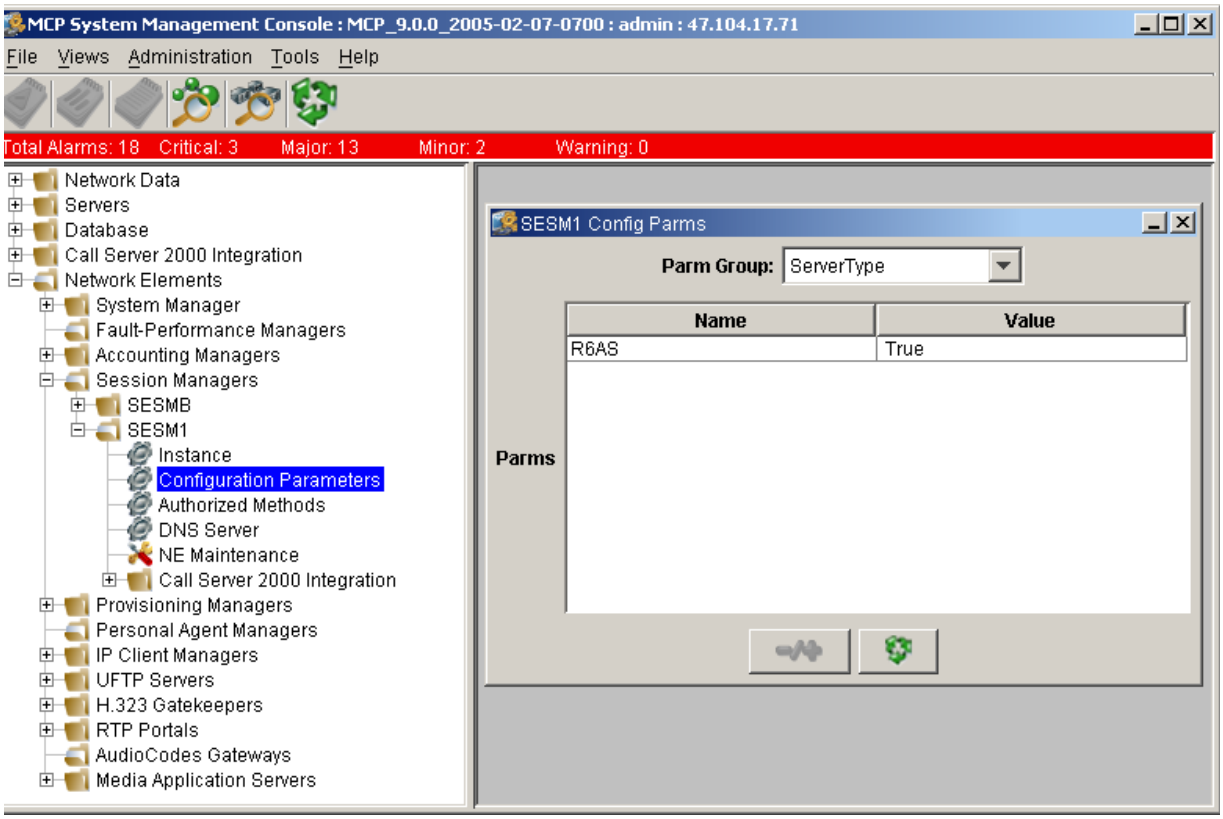
Additionally, there are a large number of client based services and AS services which are not affected by any software changes incurred by this feature. However, these services will not be tested, and are therefore not officially supported. Nevertheless, these services are expected to still function properly.

- Presence
- Automatic Software Update
- Codec selection
- Profile manager
- Quality of Service (QoS)
- Mute
- Decline
- Call subjects
- Do not disturb
- Ignore
- Outlook integration
- Call logs
- Directory (global address book),
- Import Outlook* contacts
- Personal Directory
- Clipboard
- File exchange
- Shared Whiteboard

- Sharing
- Call Waiting
- IM Broadcast
- Web push (Client)
- Whiteboard
- Decline

74.4 Proposal for R6 AS Provisioning

A new SessionManager configuration item will be added in the System Manager to configure a SessionManager as a R6 AS or standalone Session Manager.



A change to the setting of this parameter will require a restart, otherwise the AS will not see the change. If the change occurs while the AS is in service, an alarm (family: R6AS) will be generated. This alarm will not be clearable: it will only go away when the AS is restarted.

74.5 AS Orig/Term Call Half Determination

In order to meet the ½ call model 3gpp requirement, the AS is introducing a new, proprietary parameter into the route header, as follows:

An MCS R6 AS shall require that INVITES it receives from CSCFs contain, in the route header, the parameter nt_info, with its value set to one of: orig or term (e.g. "Route:<sip:appserver,lr,nt_info=orig").

An AS receiving the nt_info parm with a value of “orig” (e.g. "Route:<sip:appserver,lr,nt_info=orig"), will only execute services for the originating user specified in the "From" header of the INVITE. This is not supported in this release. If this shall occur, the AS will reject the request.

An AS receiving the nt_info parm with a value of “term” (e.g. "Route:<sip:appserver,lr,nt_info=term"), will only execute services for the terminating user specified in the Request URI.

If the AS receives the nt_info parameter set to any other value other than those discussed here, the AS shall reject the request.

If the MCS R6 AS receives a request without a route header or with a header, but without an nt_info parameter, the AS shall execute services in a full call model. In other words, the R6 AS will behave as a standalone MCS AS. This is not supported in this release. The behaviour of the AS in this situation is undefined.

Furthermore, in the case where nt_info=term (or nt_info=orig when it is supported in a future release) is present in the Route header, the R6 AppServer shall, upon completing the execution of the terminating (or originating) subscriber services, send an INVITE when applicable, with the destination in the request URI, to the node listed in the route header received in the INVITE.

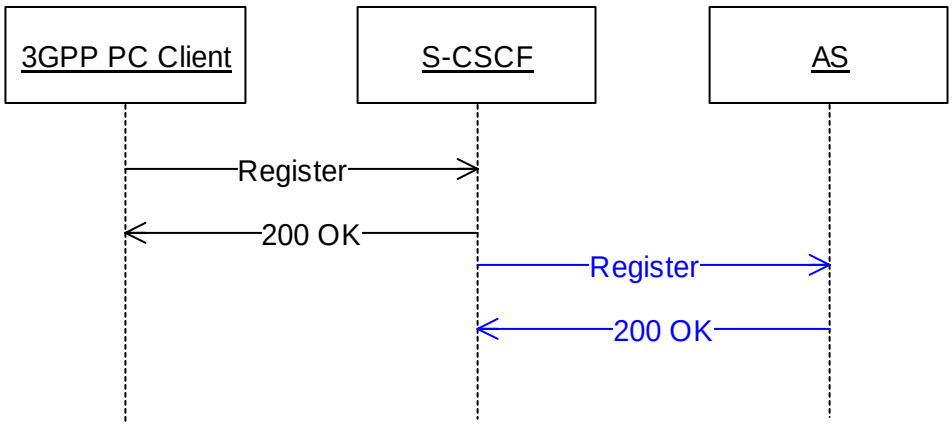
74.6 R6 AS Call Flows

74.6.1 Registration

In a 3GPP network, the 3GPP PC Client performs the registration of it’s public address with the S-CSCF and not with the Application Server. The S-CSCF stores the UE registration information in the HSS. Furthermore, all elements requiring access to UE registration information obtain it from the HSS, and a fully 3GPP compliant AS is no exception. A 3GPP AS uses its Sh interface to communicate with the HSS and obtain UE registration information.

However, in this release, the MCS R6 AS does not support the Sh interface and therefore it cannot use the HSS to retrieve registration information. Therefore, UE registration information must also be stored in the MCS R6 AS database. This is achieved by configuring the S-CSCF to perform 3rd Party Registrations (registrations on behalf of the UE) with the MCS R6 AS.

A 3rd Party Registrations message flow is depicted in the message diagram below.



Note: The message sequence that occurs between the client and the CSCF elements other than the S-CSCF have not been included in this flow. Only the message sequence between the S-CSCF and the MCS Application server has been detailed accurately. For the message sequences between the other 3GPP network entities please refer to the S-CSCF ISC document.

In 3rd Party registrations it is important to recognize the following:

- From the UE's perspective, its registration procedures have culminated once the S-CSCF sends the UE a 200 OK response to the REGISTER message.
- The S-CSCF sends the UE a 200 OK response for the REGISTER message before the S-CSCF has commenced any 3rd party registration attempt with the AS.
- A successful/failed 3rd Party Registration procedure between the S-CSCF and AS has no impact on the **outcome of the registration procedure** between the UE and the S-CSCF.

The S-CSCF shall include the following key items in its 3rd Party Registrations REGISTER message:

- The To header shall contain the public identity of the user on whose behalf the registration is being performed.
- The From header shall contain the contact address of a trusted S-CSCF node
- The Contact header shall contain the contact address of the S-CSCF serving the UE. The AS has no way of verifying the validity of this address, therefore, if the wrong S-CSCF is specified here, calls will not terminate to the UE.

- The Expires header shall contain an expiration timer value equal to the value it sent to the UE in the 200 OK response. The MCS R6 AS will permit for this value to be outside of its provisioned min/max range.

Note that the expiry timer min/max are no longer enforced at the AS, this is expected to be performed now at the S-CSCF/HSS. Also, the 3rd Party Registration does not get challenged by the MCS R6 AS due to the trusted relationship between it and the S-CSCF performing the registration.

Multiple registrations will not be blocked at the MCS R6 AS. However, terminating to a client which has multiple registered destinations will result in the AS only contacting the client's most recent registered destination. This behaviour is due to the S-CSCF's lack of support for simultaneous ringing.

In the following sample messages, the S-CSCF is located at 1.2.3.4 and the AS is at: 5.6.7.8

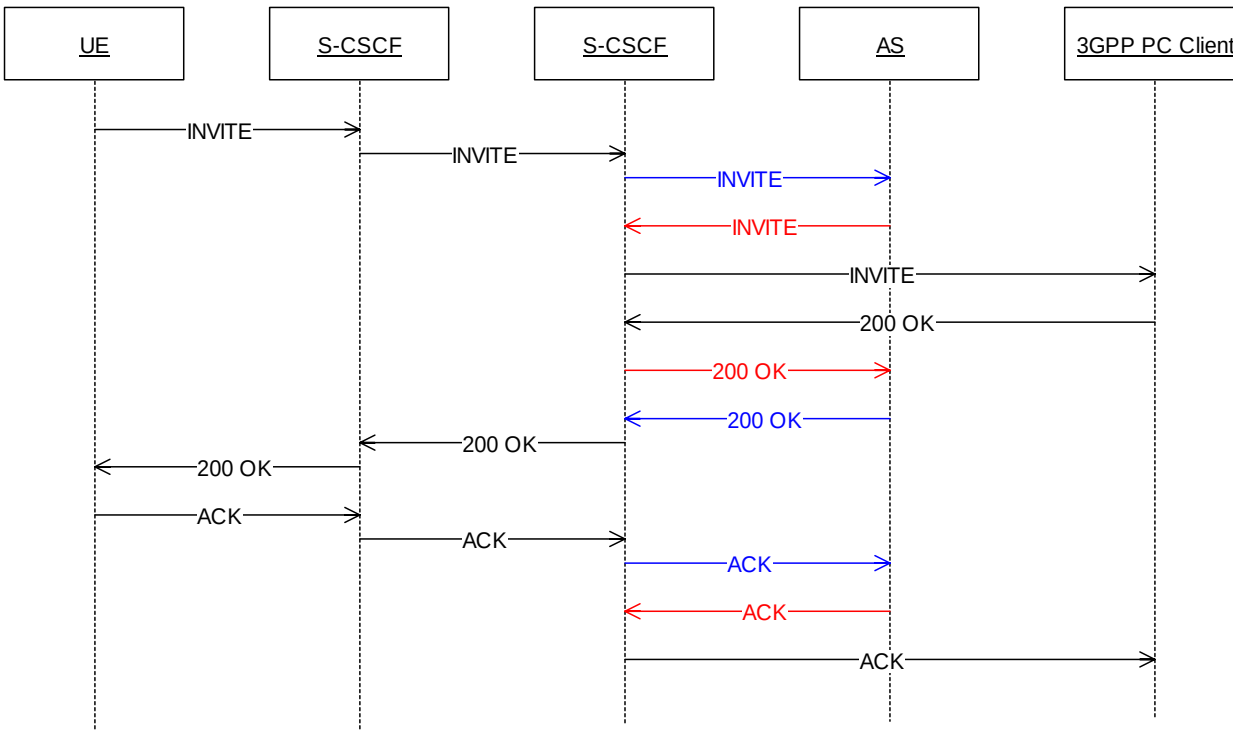
74.7 Basic call

In a non-R6 Application Server, a call attempt between two clients results in the originating client sending an INVITE directly into the AS. This INVITE is then processed by the AS and, as part of this procedure, the AS runs the subscriber originating and terminating services as necessary. Finally, the AS routes the call directly to the registered contact address of the terminating subscriber.

However, from the point of view of the AS, a call between two clients flows differently in a 3GPP network. In a 3GPP network, the clients do not send their INVITE directly to the AS, the AS receives INVITE requests from a S-CSCF instead. Also, in a 3GPP network, such requests contain an indication of which subscriber services to execute: originating subscriber services or terminating subscriber services, but never both. Finally, once the AS has finished running the requested type of services (orig or term), an R6 AS routes the call back to the S-CSCF which initiated the dialogue, and the reqURI contains the registered contact address of the terminating subscriber.



Call scenario: An IMS subscriber calls an MCS subscriber.

High level breakdown:

1. The first S-CSCF receives the invite from the IMS client and determines (through an HSS) that this subscriber does not have originating services on an AS.
2. The S-CSCF determines (through an HSS) that the term subscriber is currently at another S-CSCF, and sends the INVITE to it.
3. The second S-CSCF receives the INVITE and determines (through an HSS) that the terminating subscriber has services on the AS, and sends an INVITE, with nt_info=term in the route header, to the AS.
4. The AS receives the INVITE and finds the nt_info parm. The value ("term") of the parm causes the AS to not run any services for the originating subscriber. However, the AS does execute the terminating subscriber services.
5. The AS finishes running the term services, and retrieves the contact address of the term party from the registration tables. This is the address of the S-CSCF. The AS places the contact address into the request URI, but sends the INVITE to the S-CSCF from which it originally received the INVITE.
6. The S-CSCF receives the INVITE and routes the call to the client.
7. The client answers the call and the 200 OK propagates through all the nodes until it reaches the originating client, which sends an ACK (again, through all the nodes) back to the terminating client.

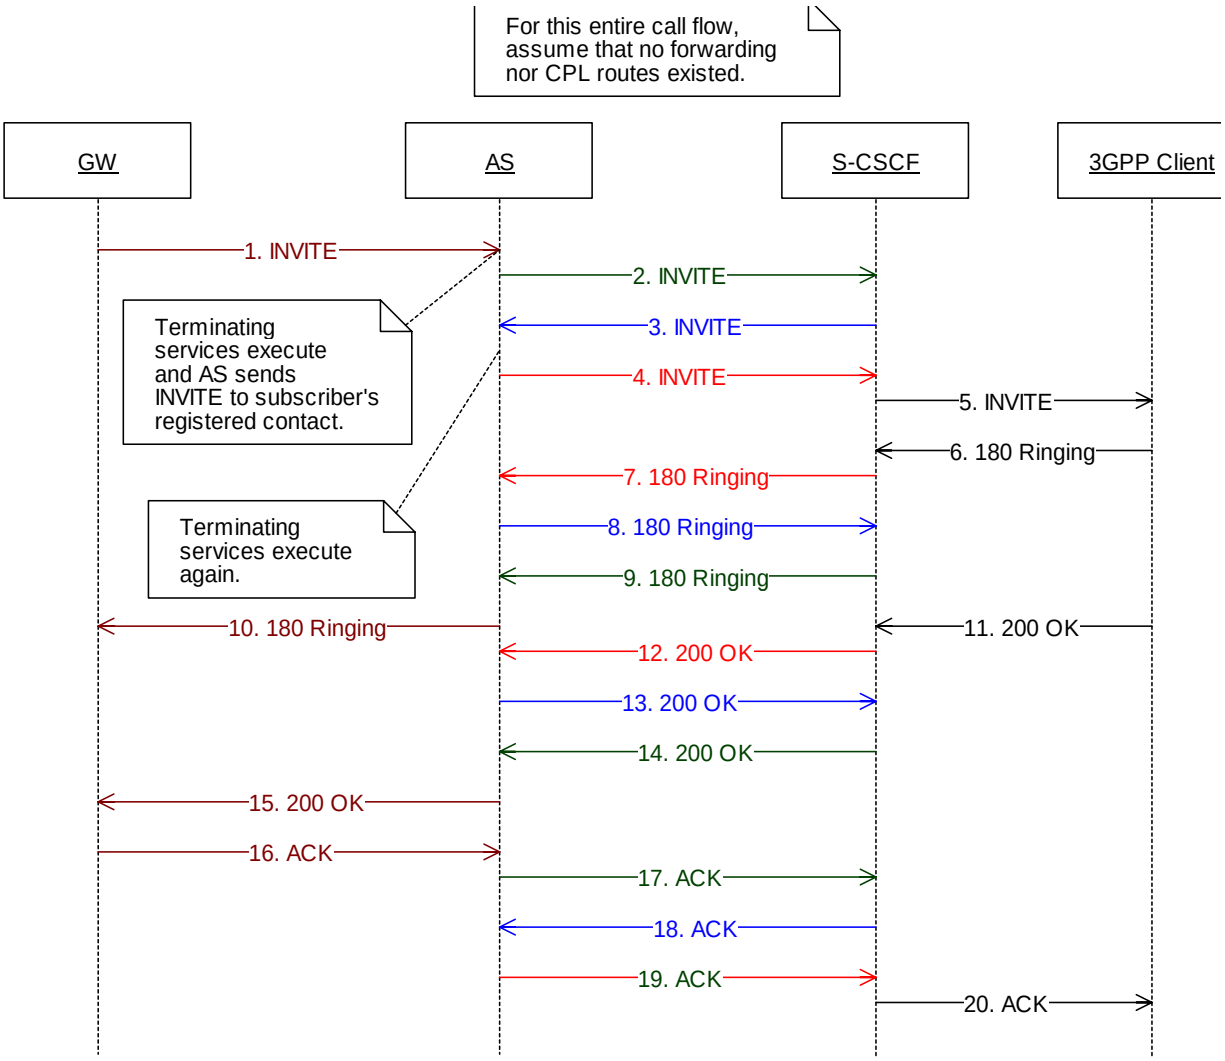
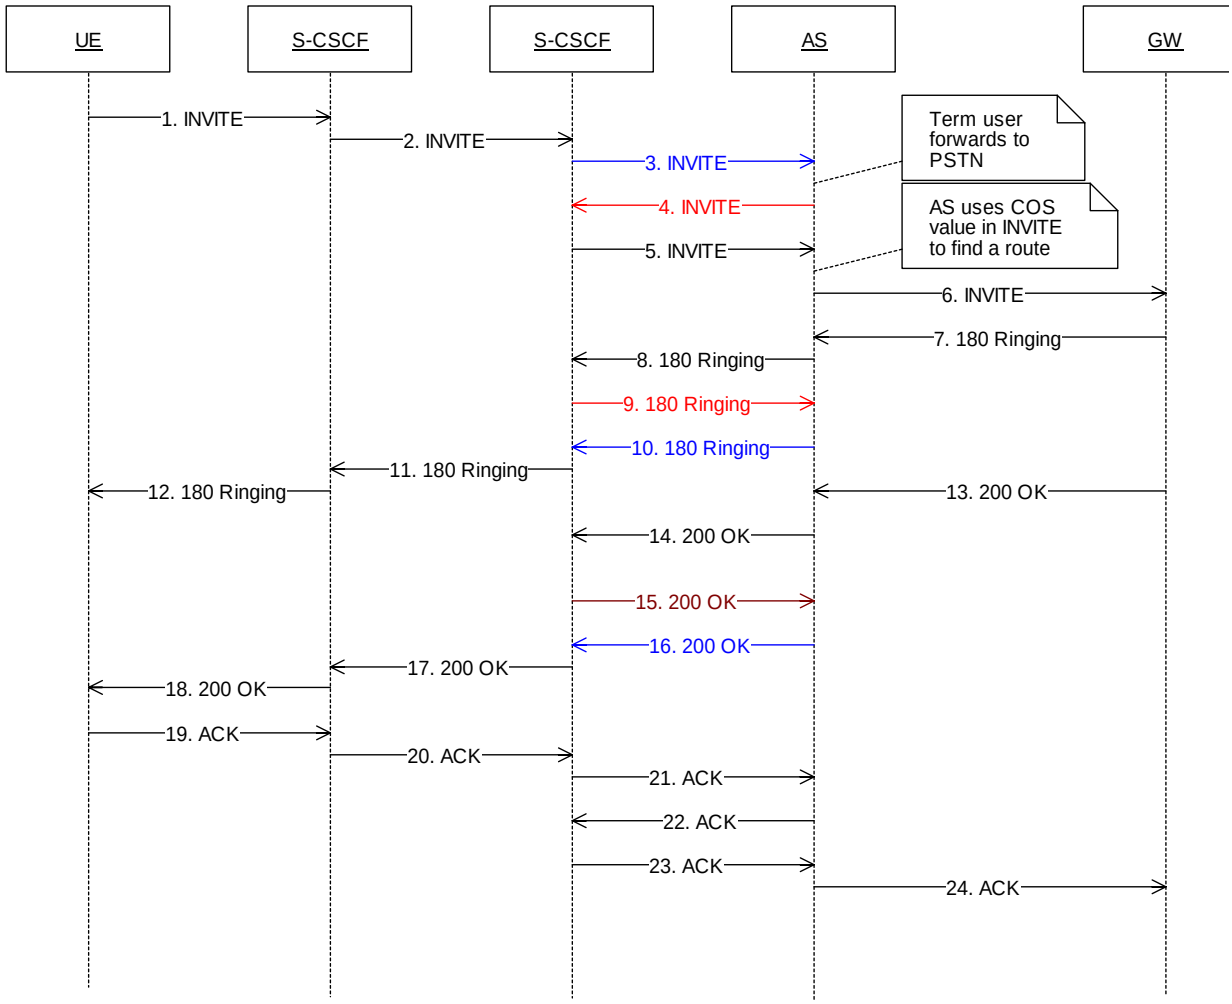
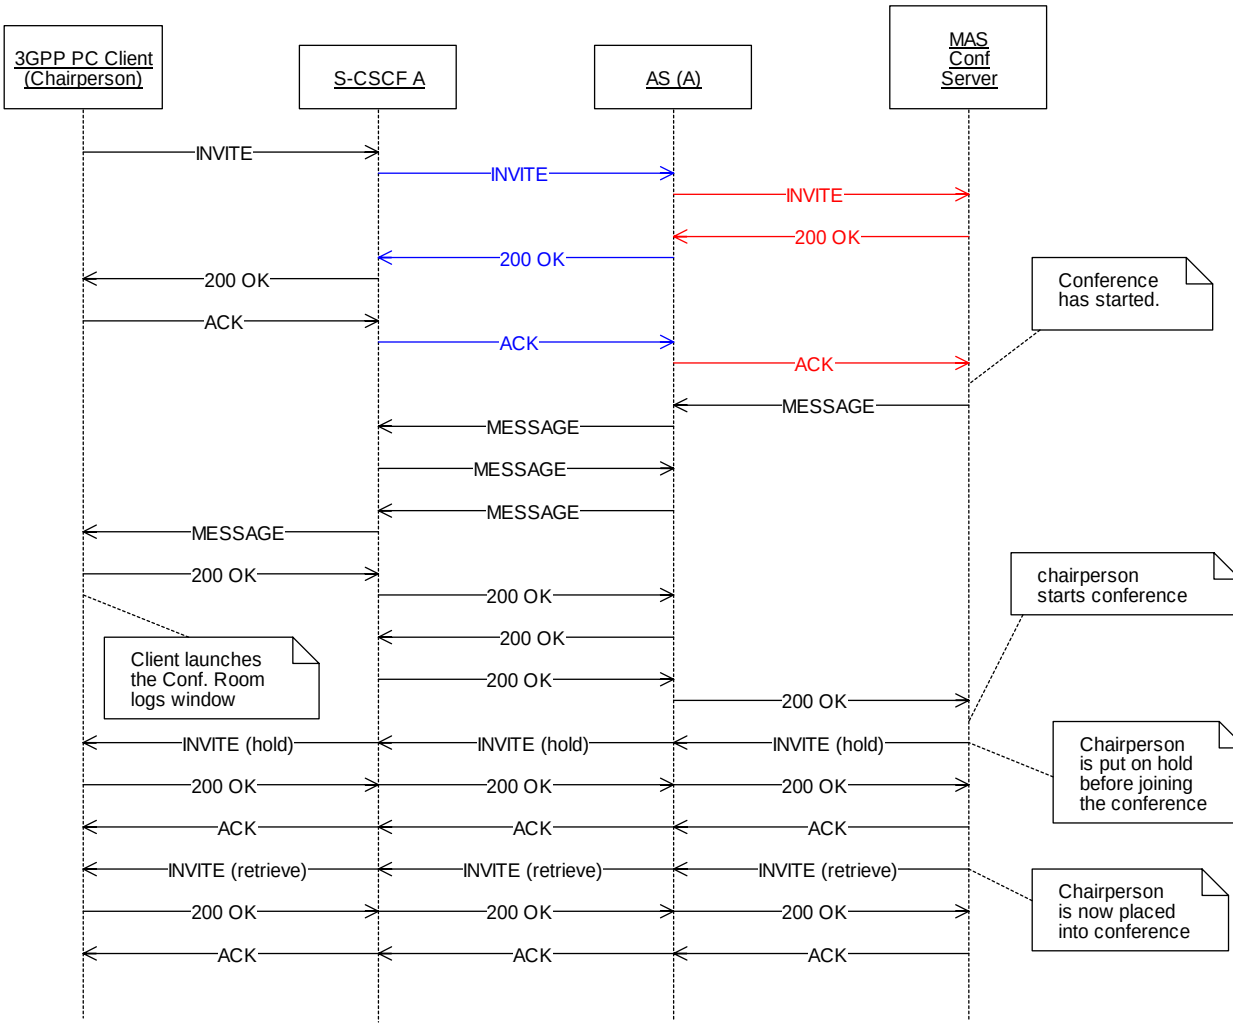
74.8 PSTN Originations

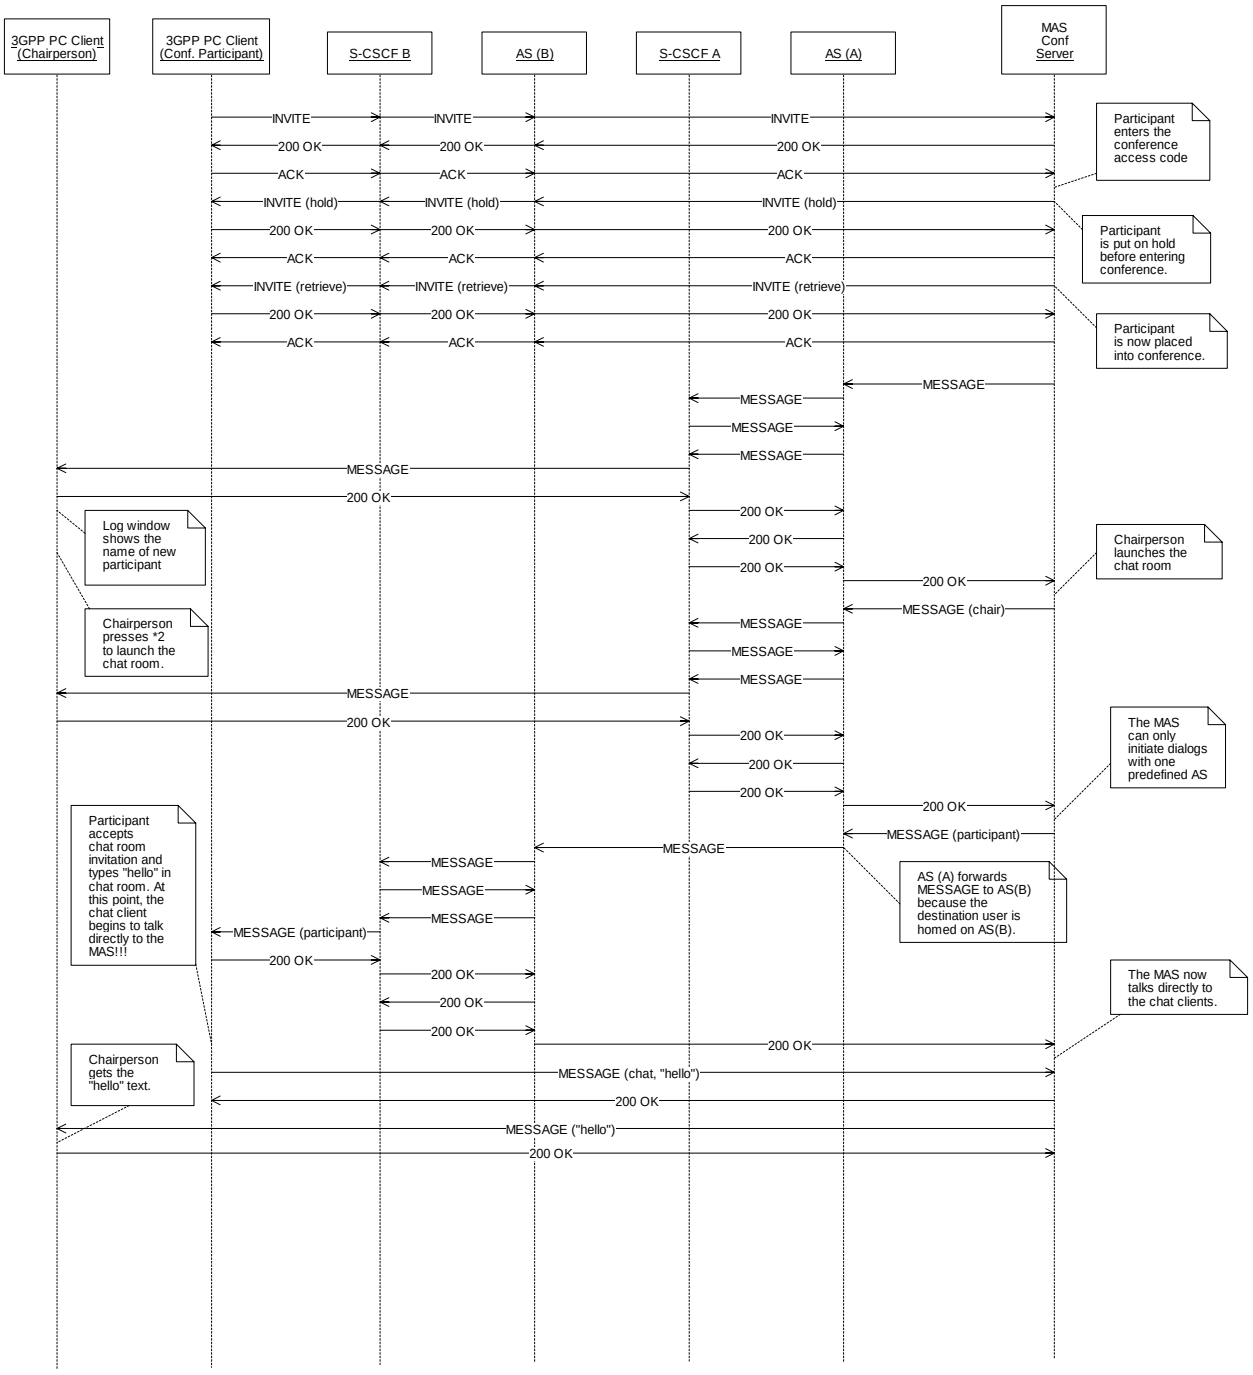


74.9 PSTN Terminations



74.10 MeetMe Conference



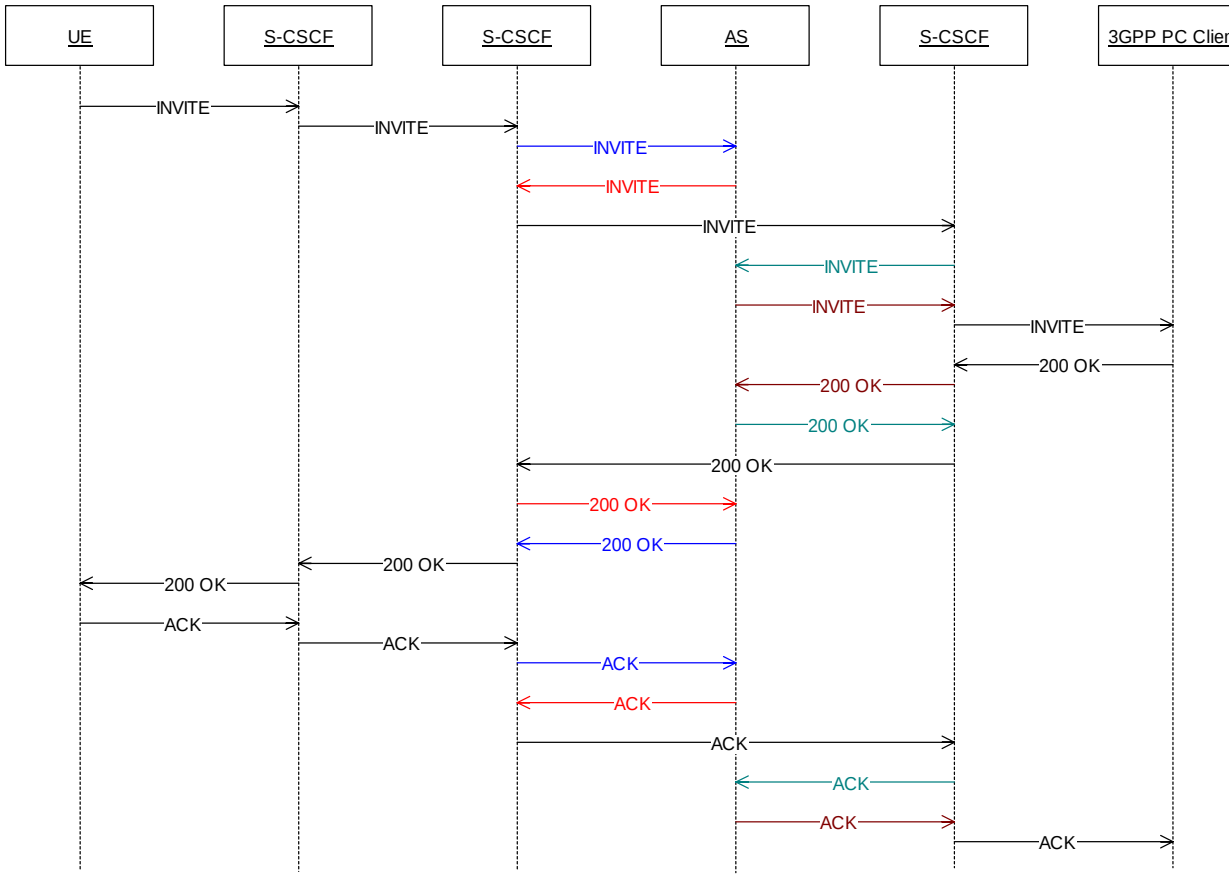


Call Scenario: An MCS subscriber calls the alias associated with the MeetMe service (eg. the user dials 4456200).

High level breakdown:

1. The S-CSCF receives the INVITE from the client and the S-CSCF has translations in place to realize that this is a call that needs to go to the MAS Conference Server.
2. The S-CSCF is not able to interact directly with the MAS (see S-CSCF documentation on the reasons why…), therefore it routes the call to the AS, and sends nt_info=term in the route header.
3. The “term” value in the nt_info route header parm causes the AS to skip originating subscriber based services. A lookup is attempted on the destination and a match is found in the pooled resource translations. Note: if a match is not found the AS will advance into telephony translations.
4. The AS sends an INVITE to the MAS Conference Server retrieved from pooled entity translations.
5. The MAS Conference server receives the INVITE, and it determines that the codecs in the SDP are supported and responds with a 200 OK. Note: will the MAS ignore the 3GPP headers?
6. The AS places the required 3GPP headers into the 200 OK and sends it to the S-CSCF, and the 200 OK propagates back to the originator.
7. The originator ACKS the 200 OK.

74.11 Call Forwarding



Call scenario: An IMS subscriber makes a call to an MCS subscriver (assume the IMS subscriber supports G.711 or G.729).

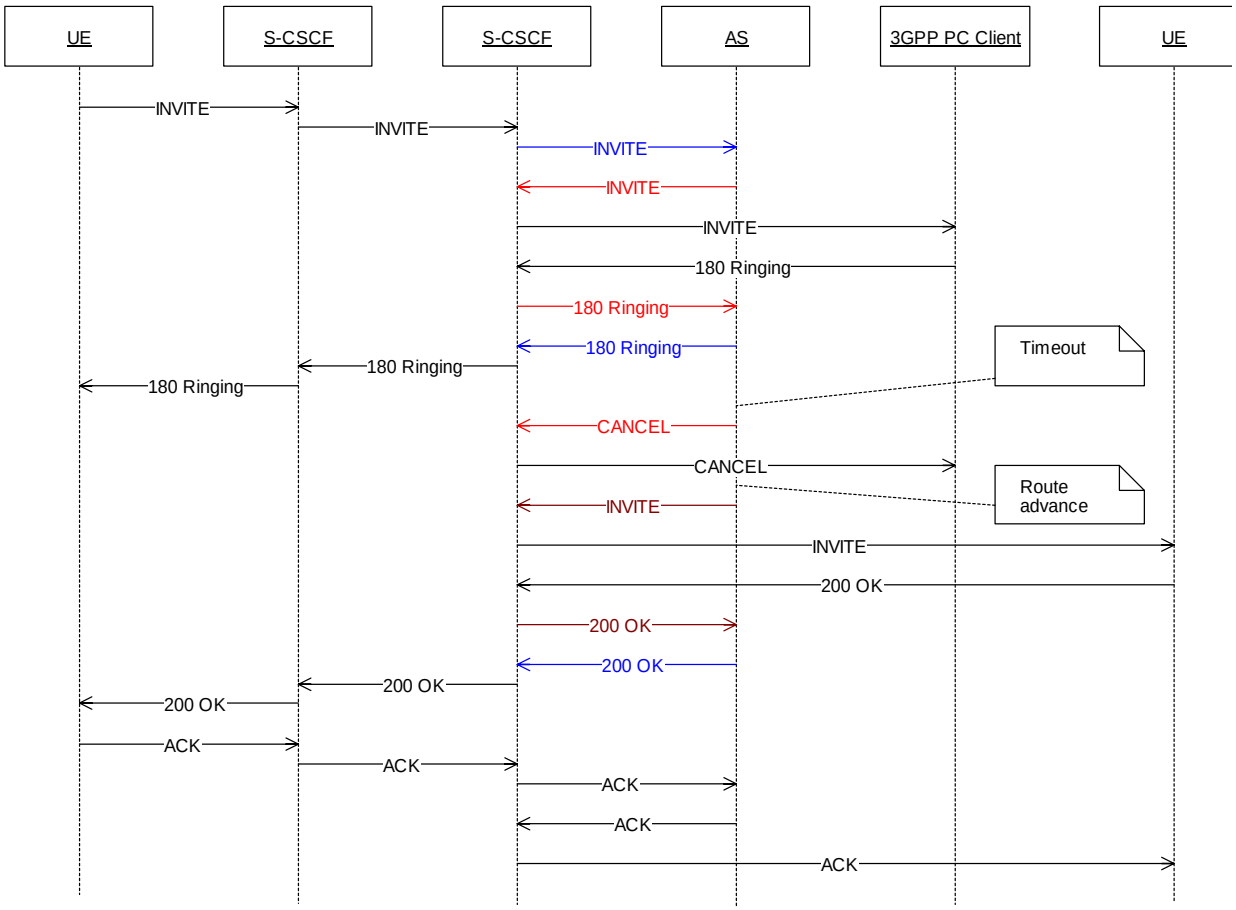
High level bereakdown:

1. The first S-CSCF receives the invite from the IMS client and determines (through an HSS) that this subscriber does not have originating services on an AS.
2. The S-CSCF determines (through an HSS) that the term subscriber is currently at another S-CSCF, and sends the INVITE to it.
3. The second S-CSCF receives the INVITE and determines (through an HSS) that the terminating subscriber has services on the AS, and sends an INVITE, with nt_info=term in the route header, to the AS.

4. The AS receives the INVITE and finds the nt_info parm. The value (“term”) of the parm causes the AS to not run any services for the originating subscriber. However, the AS does execute the terminating subscriber services.
5. While running through the term subscriber services, it determines that the subscriber has call forwarded his calls to another MCS subscriber (party C). The AS then sends an INVITE, with party C in the “to” header, to the S-CSCF which originally sent the INVITE being processed (the second S-CSCF). The Request URI is set to C’s contact address from registration. The P-Called-Party-Id header will contain the contents of the “to” header in the original INVITE (party B).
6. The S-CSCF receives the INVITE, queries the HSS and finds party C’s S-CSCF.
7. An INVITE is then sent from party B’s S-CSCF to party C’s S-CSCF.
8. Party C’s S-CSCF receives the INVITE and determines (through the HSS) that the AS should provide services for party C.
9. An INVITE is sent to the AS, and the call continues the same way it does in a basic call (see section 2.3.3.2).

74.12 Sequential Ringing

This is no longer supported due to the forking limitation found on the s-cscf. This content is left here for documentation purposes.



Call scenario: An IMS user calls an MCS subscriber who has the following rule in his personal agent CPL: ring self for 3 rings and, if no answer, route advance to ring UE3 for 3 rings.

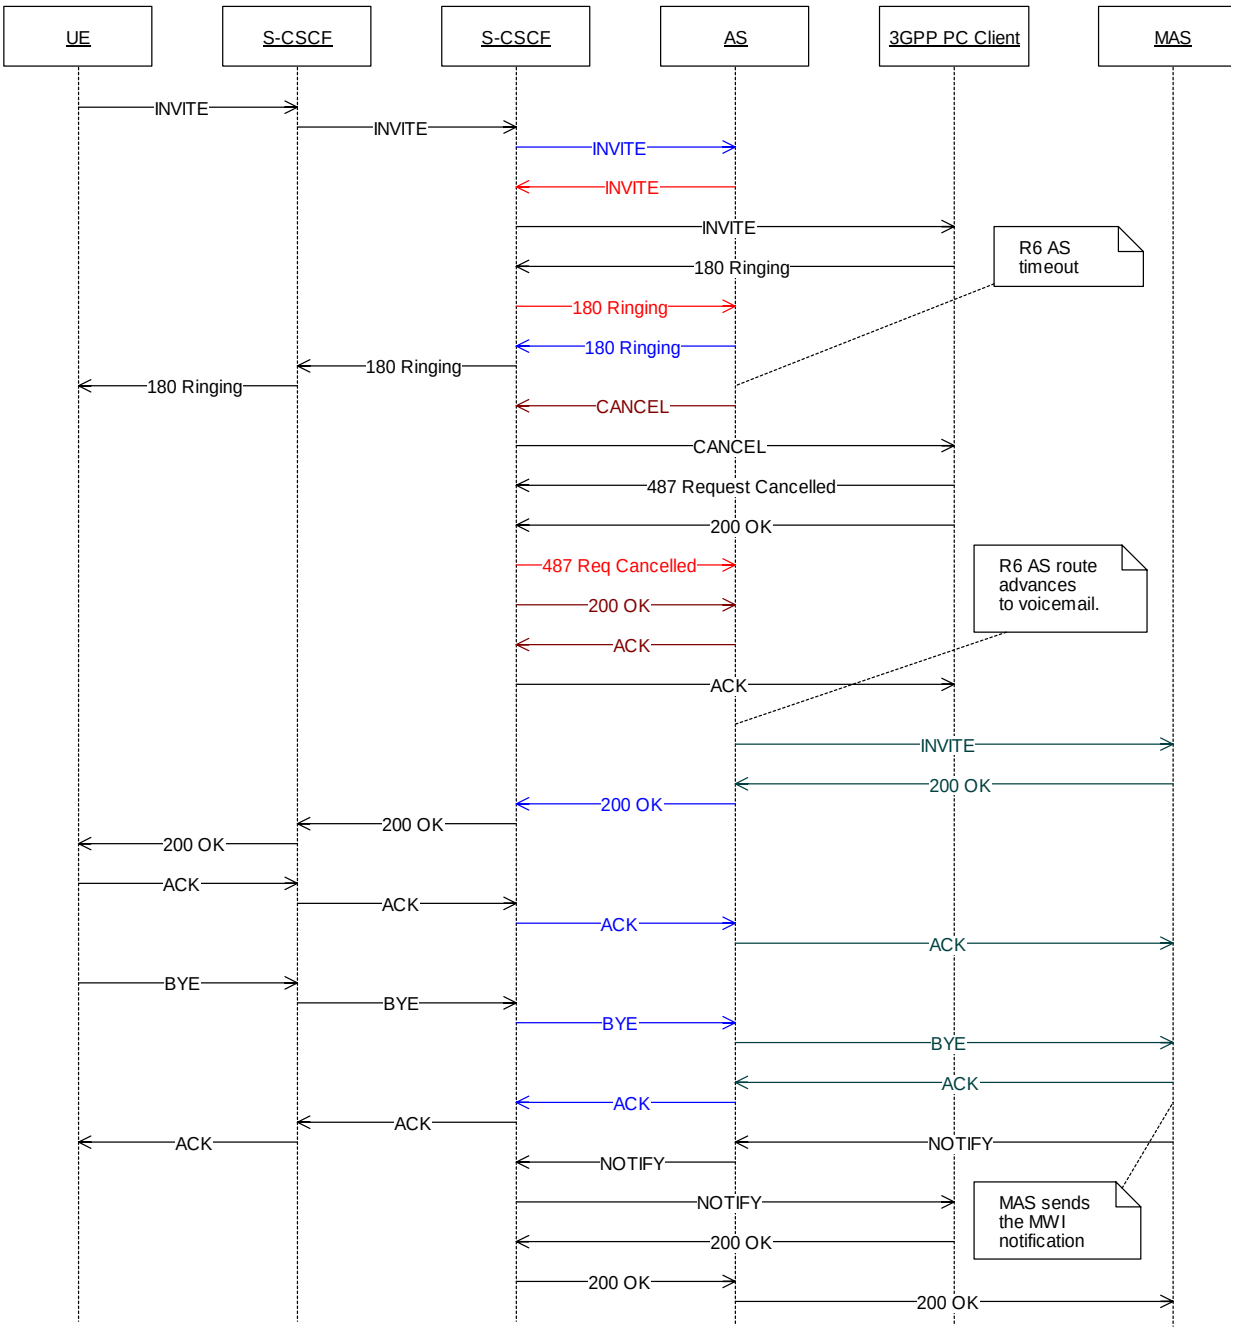
High level breakdown:

1. The first S-CSCF receives the invite from the IMS client and determines (through an HSS) that this subscriber does not have originating services on an AS.
2. The S-CSCF determines (through an HSS) that the term subscriber is currently at another S-CSCF, and sends the INVITE to it.
3. The second S-CSCF receives the INVITE and determines (through an HSS) that the terminating subscriber has services on the AS, and sends an INVITE, with nt_info=term in the route header, to the AS.

4. The AS receives the INVITE and finds the nt_info parm. The value (“term”) of the parm causes the AS to not run any services for the originating subscriber. However, the AS does execute the terminating subscriber services.
5. Upon executing the term subscriber services, the AS determines that the subscriber has sequential routes provisioned.
6. The AS sends an INVITE back to the S-CSCF which sent it the INVITE, but the INVITE has its request URI set to the contact address of the term subscriber.
7. Once the number of rings for the first route expire, the AS sends a CANCEL to the S-CSCF and route advances the same way it does in the Release 9.0 AS. The only noticeable difference is that the INVITE for the second termination is sent to the S-CSCF (the one who sent the INVITE to the AS), instead of directly to the client.

74.13 Unified Communications (Voicemail deposit)

This is no longer supported due to the forking limitation found on the s-cscf. This content is left here for documentation purposes.



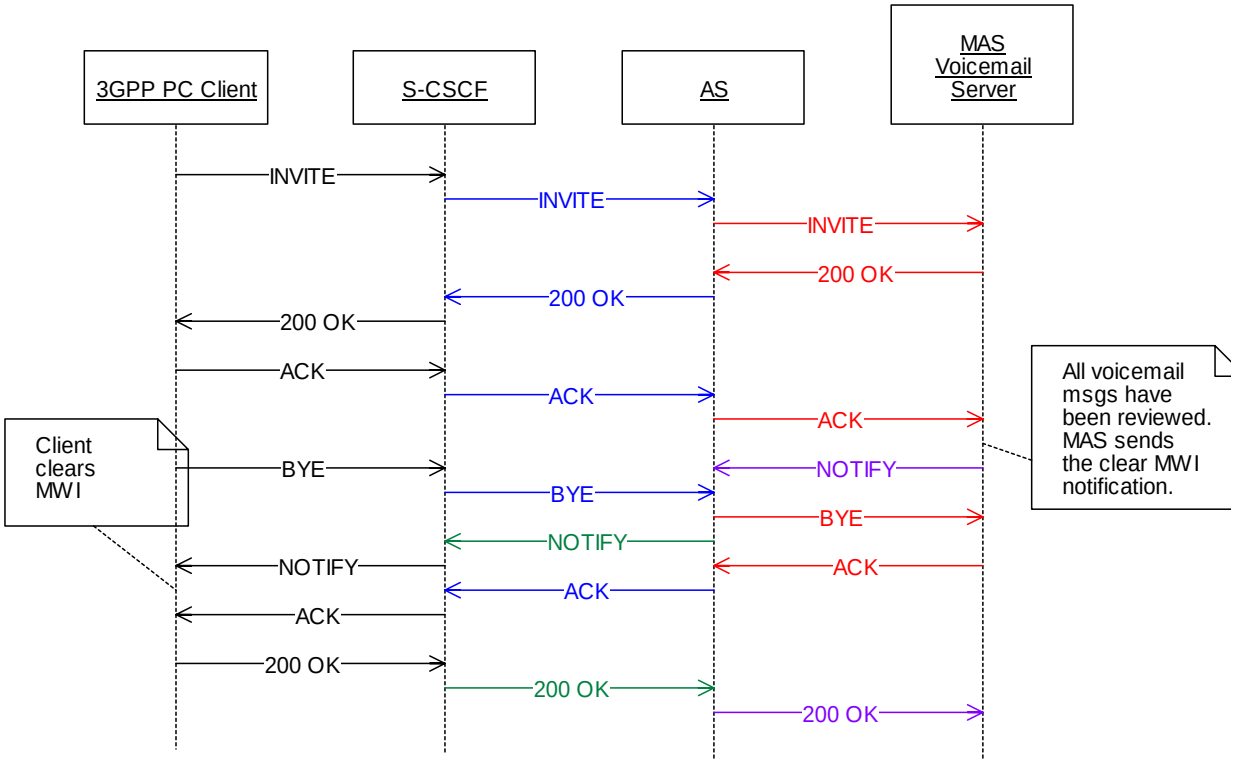
Call scenario: An IMS user calls an MCS subscriber who has the voicemail service and who does not answer the phone.

High level breakdown:

1. The first S-CSCF receives the invite from the IMS client and determines (through an HSS) that this subscriber does not have originating services on an AS.
2. The S-CSCF determines (through an HSS) that the term subscriber is currently at another S-CSCF, and sends the INVITE to it.
3. The second S-CSCF receives the INVITE and determines (through an HSS) that the terminating subscriber has services on the AS, and sends an INVITE, with nt_info=term in the route header, to the AS.
4. The AS receives the INVITE and finds the nt_info parm. The value ("term") of the parm causes the AS to not run any services for the originating subscriber. However, the AS does execute the terminating subscriber services.
5. An INVITE is sent to the S-CSCF with the client's contact address in the request URI.
6. The client fails to answer, and the AS sends a CANCEL.
7. The AS "route advances" to the MAS voicemail Server, and sends an INVITE to it.
8. The MAS Voicemail Server receives the INVITE and determines that the codecs in the SDP are supported, and replies with a 200 OK. From this point onward, the behaviour is the same as the one described (once the call is answerd) in section 2.3.3.2.
9. Once a new message is deposited into the subscriber's mailbox, the MAS will send a MWI NOTIFY message towards the subscriber. This will activate the MWI feature on the client.

74.14 Unified Communications (Voicemail retrieval)

Since VM deposit is not supported (see previous section), this is also not supported (there will never be any VM to retrieve!) This content is left here for documentation purposes.



Call scenario: An MCS subscriber calls his voicemail (eg. the user dials 445-6100) to listen to his messages.

High level breakdown: The call is identical to the call flow described for meetme conference in section 2.3.3.3. The only difference is in the NOTIFY message, sent by the MAS towards the client. This NOTIFY turns off the MWI on the client, and is only sent when all new voicemail messages have been reviewed.

Note: Add the incoming NOTIFY msg and the outgoing 200 OK (from AS point of view). Also, verify the contents of the messages already below.

AS outgoing NOTIFY:

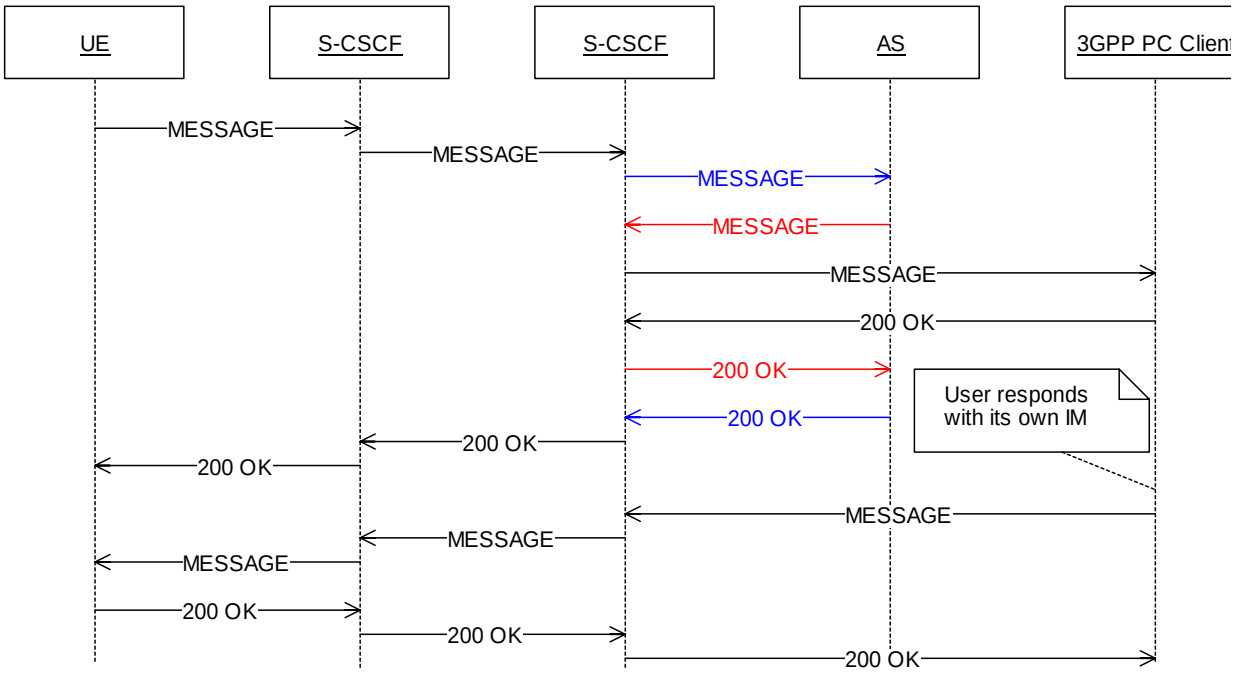
74.16 Instant Messaging



Call scenario: An MCS user receives an IM from an IMS user, and responds with his own instant message.

High level breakdown:

1. The first originators S-CSCF receives the MESSAGE and determines (through the HSS) that the destination party is currently located at another S-CSCF.
2. The MESSAGE is sent to the second S-CSCF. This S-CSCF determines (through the HSS), that the terminating subscriber has services in the AS.
3. The S-CSCF sends the MESSAGE to the AS, with nt_info=term in the route header.
4. The AS runs only through the term subscriber services, and sends a MESSAGE back to the S-CSCF request URI set to client contact address)
5. The S-CSCF sends the MESSAGE to the MCS client.
6. The MCS client displays the received instant message.
7. The MCS subscriber then types his own instant message and sends the MESSAGE back to the second S-CSCF (it was the one in the contact header?)

8. This S-CSCF determines (through the HSS) that no originating services are supported at the AS for this client, and it does not contact the AS.
9. The S-CSCF determines (through the HSS) that the terminating user is at another S-CSCF and forwards the MESSAGE to the other S-CSCF.
10. The first S-CSCF determines through the HSS that the destination subscriber is not an MCS user and therefore just sends the MESSAGE to the client.

74.17 Hardware Requirements or Dependencies

The R6 MCS Application server will only be supported in the same configuration as the 9.0 Standalone MCS. At this time, this translates to an eight N240 server configuration. However, because the R6 AS does not support interactions with IPCM and Gatekeeper, the number of N240 servers is reduced to 6.

Also, in this release, the R6 AS does not support interactions with a Media Portal. The target network for this release is not expected to require this node because there are no NATs or firewalls in the network.

74.18 Software Requirements or Dependencies

The R6 AS and its supporting MCS nodes shall use the same loads as their equivalent nodes in the 9.0 MCS Standalone configuration.

The only difference between the two deployments shall be the value assigned to a System Manager configuration parameter which converts the MCS SessionManager into the R6 AS.

74.19 Limitations and restrictions

Refer to the Feature Description section.

74.20 Interactions

None.

74.21 Glossary

Term	Description
New term	definition

75: Functional description (FN): A00009443

75.1 Feature name and Feature ID

T.38 Annex D for NGSS , activity A00009443.

75.2 Description

75.2.1 Overview

The main part of this activity provides support for H.248 T.38 Annex D interworking with SIP. This functionality is only available if both the remote MTA and SIP server support T.38 Annex D. A new provisioning flag **T.38 Annex D Supported** is added to the remote server option list to indicate that the remote server supports T.38 Annex D.

The call scenarios covered by this feature are described by ITU-T T.38 Annex D, specifically section D.2.2.4 - Voice and facsimile connection.

This activity intends to provide T.38 Annex D interworking support for SIP with H.248 PVG on the local side. For this feature to work, the Gateway controller must have T.38 enabled in the network codec profile provisioning, the H.248 GW PVG must support T.38, and the **T.38 Annex D Supported** flag must be enabled in the NGSS provisioning remote server option page. If so, then upon fax detection, a switch over is performed from G.729 (or G.711) to T.38 codec.

The switch-over is performed using an existing mechanism based on sending a re-Invite message with the new codec in the SDP. If the offer is accepted, the call switches to T.38 mode once the re-Invite sequence completes.

In case that a switch attempt is rejected by either end, an attempt will be made to preserve the call by switching to G.711 codec.

This feature is done in parallel with SN09 activity A00009294 which is responsible for the connection broker changes in the GWC.

The second part of this feature provides ability to prevent automatic upspeed from G729 to G711 by 248 PVG on fax detection as is the default PVG behavior. A new field **Re-Invite for Voice Band Data** is added to enable this functionality. If this field is enabled, the PVG will not auto upspeed to G711 but send a Re-Invite upon fax detection, to switch either to G711 codec or to

T.38 if **T.38 Annex D Supported** is provisioned. Note that if the original media for the call was set up using G711 codec, the new field has no effect, and the call behavior is dependent only on whether the **T.38 Annex D Supported** is enabled or not, as described above. If both **Re-Invite for Voice Band Data** and

75.2.2 Scenarios covered by this activity :

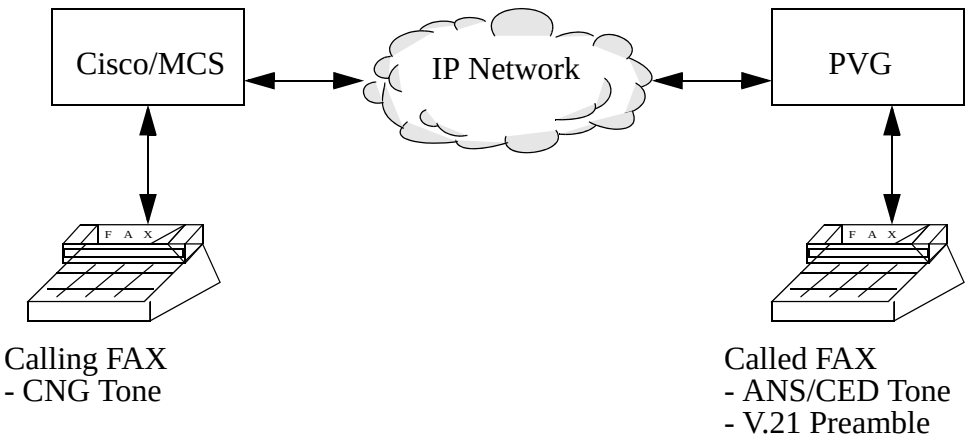
There are 2 basic T.38 scenarios covered by this feature, as illustrated in the following figures. Figure 1 shows a scenario in which PVG detects the T.38 tones and initiates the switch. Figure 2 shows a scenario in which T.38 tones are detected by the Cisco/MCS which initiates the switch to T.38.

Note that for the T.38 call scenarios covered by this feature it does not matter which side originated the original voice call, but which gateway sends the T.38 tones (emitting gateway) and which gateway (receiving gateway) detects the tones and initiates the switch. For this feature, it is always the receiving gateway that initiates the switch.

The call scenarios that use the field **Re-Invite for Voice Band Data** are very similar to the T.38 call scenarios discussed here. If the **Re-Invite for Voice Band Data** is provisioned, but **T.38 Annex D Supported** is not, then the call switches to G.711 codec upon fax detection exactly in the same fashion as described below for T.38. If both fields are provisioned, PVG end will attempt to switch first to T.38, and if the attempt is rejected by the far end which does not support T.38, PVG will send another Re-Invite to switch to G.711.

75.2.2.1 T.38 fax calls originating from SIP/NGSS and terminating at PVG.

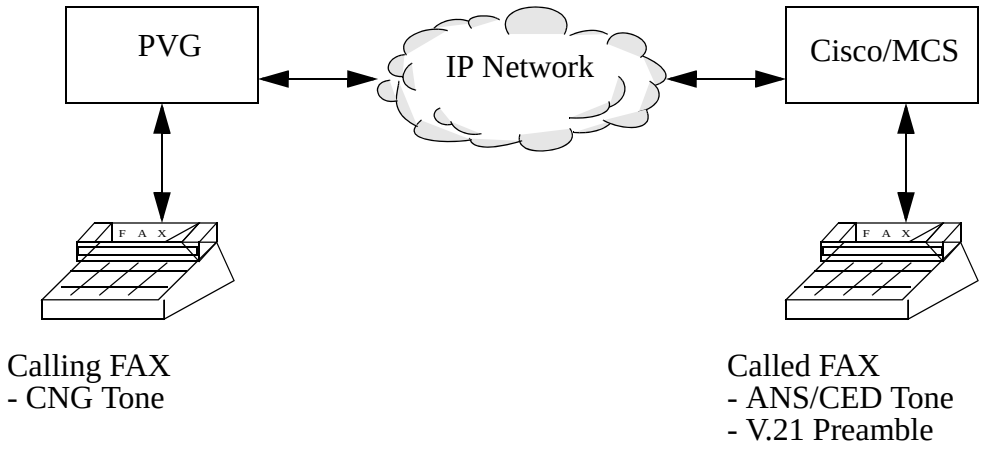
Figure 1



- A SIP Invite is sent to the CS2K by the CISCO/MCS requesting a voice connection.
- A voice connection is then established.
- Upon detection of fax tone the receiving gateway , PVG, it sends a V.21 notification to CS2K.
- CS2K then sends a SIP Re-Invite request to the emitting gateway (with the same Call-ID as the already existing voice connection) for a T.38 facsimile connection.
- Upon completion of the facsimile call establishment, the T.38 fax call proceeds with a T.38 V.21 flags indicator packet.

75.2.2.2 T.38 fax calls originating from PVG and terminating at SIP/ NGSS.

Figure 2



- For calls originating from the PVG end, a SIP Invite is sent to the CISCO/ MCS requesting for a voice connection.
- A voice connection is established.
- A V.21 notification is received by the CISCO/MCS.
- It sends a re-invite to the originating side PVG, and the switch-over to T.38 occurs.

75.2.3 New functionality provided by this feature

75.2.3.1 Provisioning

Two new provisioning fields are added by this feature.

A new boolean provisioning flag **T.38 Annex D Supported** is added to the NGSS option list on the remote server provisioning web page to indicate that the remote server supports T.38 Annex D. This flag has to be set to 'Y' to enable this functionality. It should be set to 'Y' only if the remote SIP server supports T.38 Annex D.

A new boolean provisioning flag **Re-Invite for Voice Band Data** is added to the NGSS option list on the remote server provisioning web page to prevent automatic upspeed from G729 to G711 by 248 PVG on fax detection as is the default PVG behavior. This flag has to be set to 'Y' to enable this functionality. It has no effect on non-PVG gateways.

75.2.3.2 Proprietary header for the SIP INFO message

A SIP info message is used to tandem the T.38 scan request to the other CS2K. It contains a new proprietary Nortel SIP header to indicate to the other CS2K that it should scan for T.38 tones.

The new header is defined as follows:

x-nt-action-req = "action" HCOLON action-value *(";" action-value)
action-value = "t38annexd" / "vbdannexd"

The following is an example of the SIP INFO message using this header:

INFO sip:9192461814@MGCA;user=phone SIP/2.0
Via:SIP/2.0/UDP MGCA;maddr=47.174.75.160
To:<sip:9192461814@MGCA;user=phone>
From:<sip:2461817@MGCA;user=phone>
Call-ID:0111.5119-22-19-49-11.68@MGCA
CSeq:1 INFO
X-nt-action-req: t38annexd
Content-Length:0

If a SIP info message containing the above header with action value of '38annexd' is received by an NGSS in any CS2K, it should have the same meaning as if the **T.38 Annex D Supported** was provisioned on the NGSS. The CS2K should start scanning for T.38 fax tones and initiate the switch to the T.38 codec if detected. In a similar fashion, a SIP info message containing

the above header with action value of ‘vbdannexd’ received by an NGSS in any CS2K should have the same meaning as if the **Re-Invite for Voice Band Data** was provisioned on the NGSS.

75.2.3.3 Call preservation in case of codec switch rejection.

In case that the remote SIP server rejects a re-Invite message initiating the switch to T.38 by sending a 488 Not Acceptable Here response, the CS2K will attempt to preserve the call by sending another re-Invite with G.711 codec offer. If this offer is accepted, the call will be preserved.

In case that the PVG rejects the attempt to switch to T.38 codec initiated by the remote server re-Invite, the CS2K will respond with 488 Not Acceptable Here message. It is up to the remote SIP server to initiate a switch back by sending another offer in the re-Invite.

75.2.4 Supported Call Flows

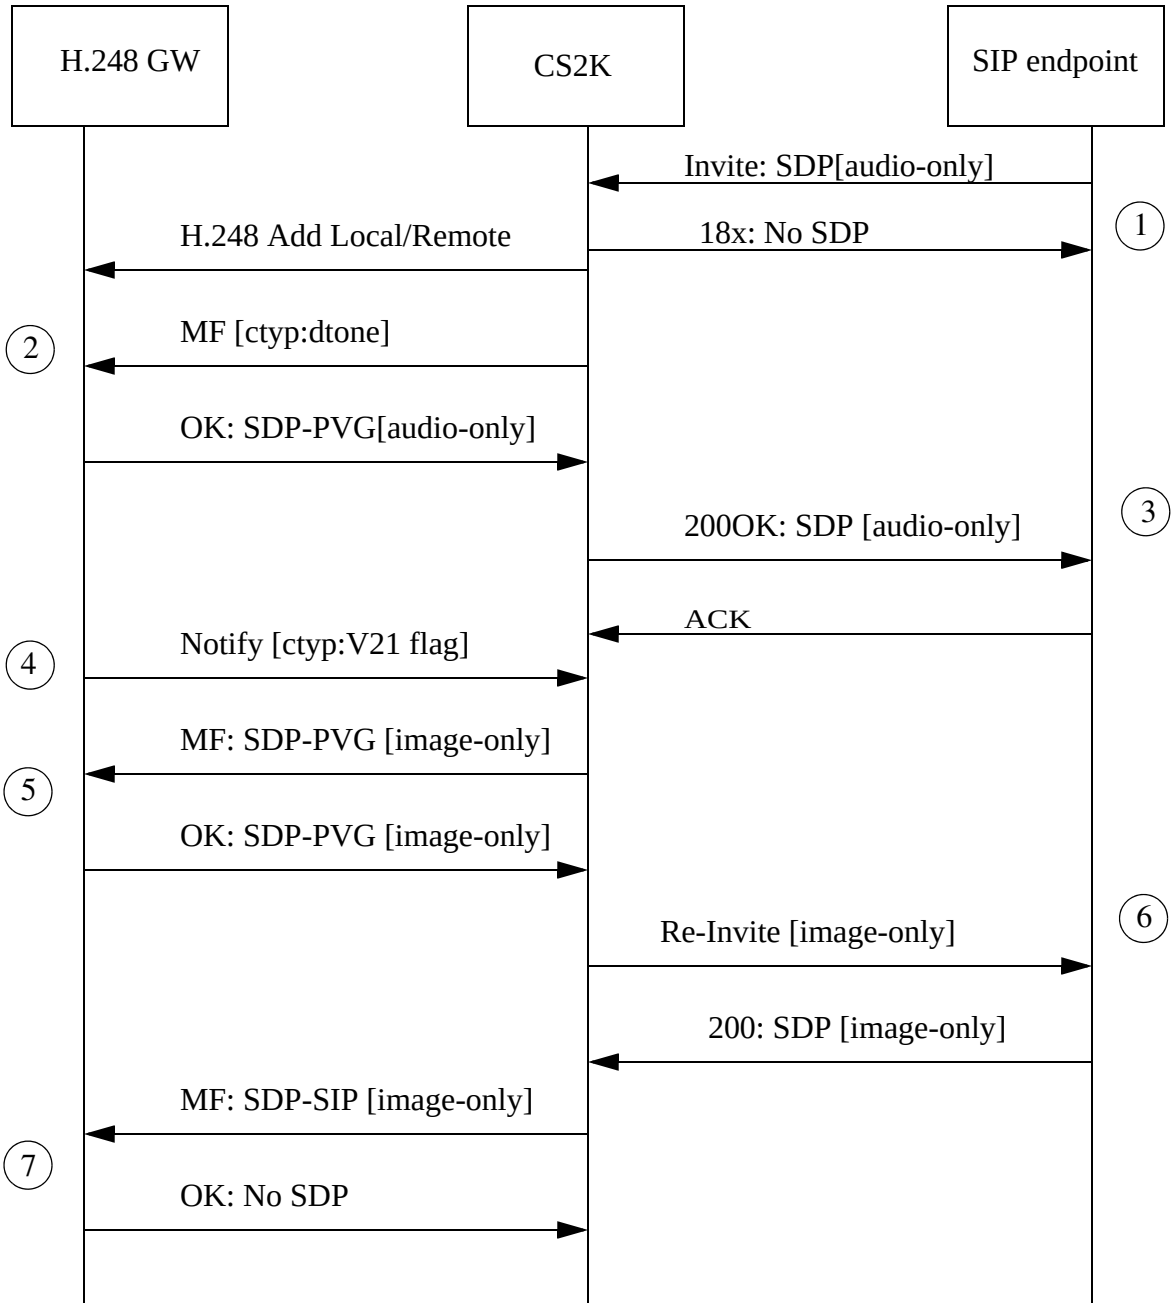
Description of T.38 Annex D functionality is provided via call flows provided in the following figures . The description of the first call flow is given in detail and may be applied to other subsequent call flows.

75.2.4.1 Basic Call Scenario: SIP to PVG interworking.

When the call is originated from the CISCO/MTS SIP endpoint:

In this scenario, the voice call is call originates from CISCO/MTS in the form of SIP INVITE sent to CS2K. Since the **T.38 Annex D Supported** is enabled in the NGSS for the remote server, during the voice call setup the PVG is asked to scan for fax tones. A voice call is established successfully, and then PVG detects a V.21 flag. V.21 Fax notify is sent from PVG which triggers an attempt to change the codec from G.711 or G.729 to T.38 communicated to the remote end via a re-Invite sequence.

Figure 3 T.38 Calls originating from CISCO/MTS and terminating at PVG on CS2K



Note 1: After receiving an INVITE from the SIP endpoint, a voice call is established. If in the Gateway controller configuration, T.38 is enabled in the network codec profile provisioning the ephemeral is added, and the PVG is asked to choose from m = audio $$$ m = image $ udptl t38.

Note 2: If the **T.38 Annex D Supported** flag is enabled on the remote server , the H248 GWC requests the PVG to scan for all events on the ctyp/ dtone package.

Note 3: The PVG replies with the intersection of the PVG capability and the offer from SIP Invite, which is sent to the remote SIP end point. At this point voice call is established.

Note 4: The PVG then reports any detected ctyp/dtone event to the GWC.

Note 5: Upon detection of a CNG or a V.21 flag the GWC will send a modify to the PVG with the local descriptor m=image $ udptl t38.

Note 6: CS2K sends this image only SDP to the remote SIP end point in Re-INVITE message.

Note 7: Upon receipt of SDP(T.38) from remote SIP end point, CS2K sends a modify indicating the offer has been accepted. At this point T.38 fax call is established.

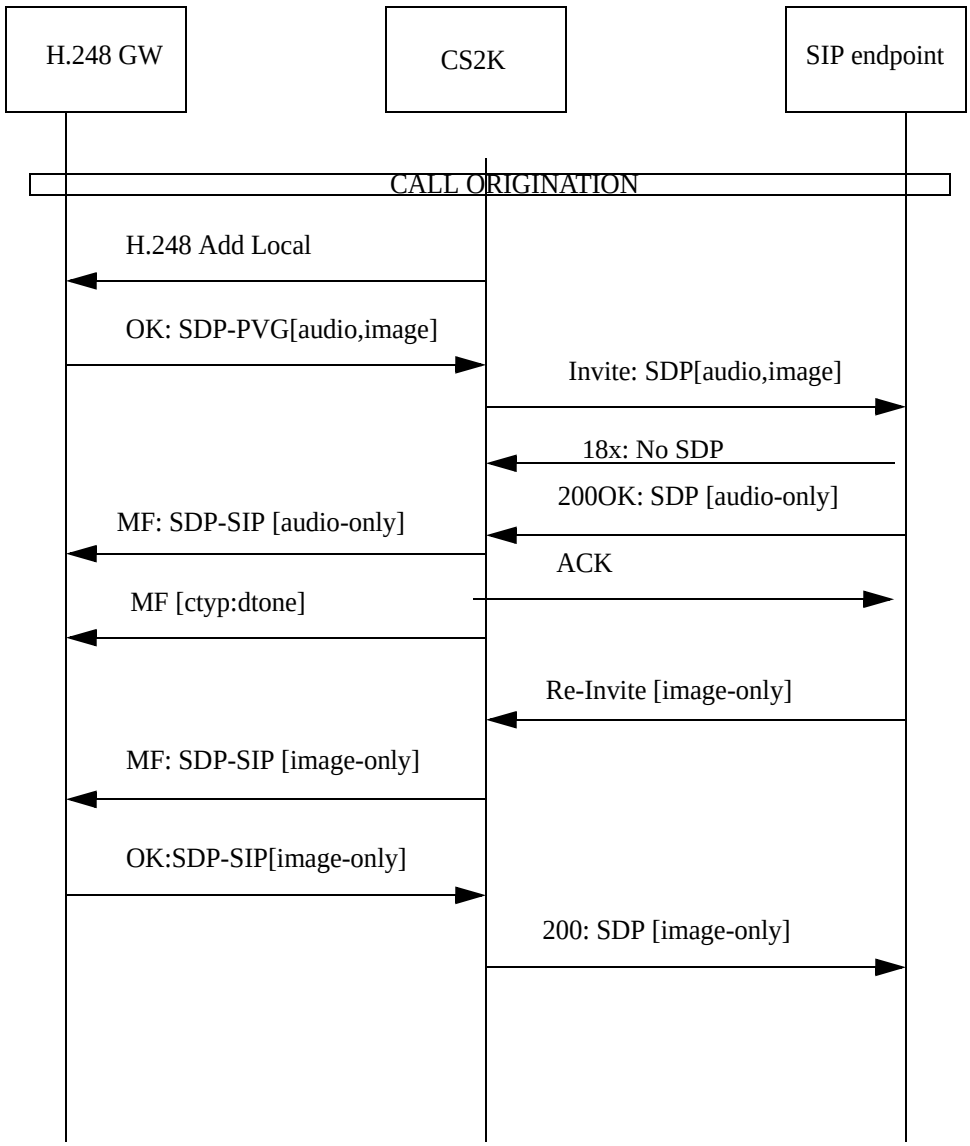
Note 8: The content of SDP uses following abbreviation:

- SDP(audio) for processing of audio media stream.
- SDP(t38) for processing of t38 media stream.
- SDP(audio, t38) for simultaneous processing of audio and t38 media streams.
- SDP(audio, t38-cap) for processing of audio media stream and for t38 capability indication.

75.2.4.2 Basic Call Scenario: PVG to SIP interworking.

When a call originates from PVG, a SIP INVITE is sent from CS2K to the SIP Endpoint which replies with its SDP. Since the **T.38 Annex D Supported** is enabled in the NGSS for the remote server, during the voice call setup the PVG is asked to scan for fax tones. After the voice call is established successfully the remote receiving gateway detects V.21 flag and starts the re-Invite sequence leading to change from G.711 or G.729 codec to T.38. Once the sequence completes, the T.38 fax call is established.

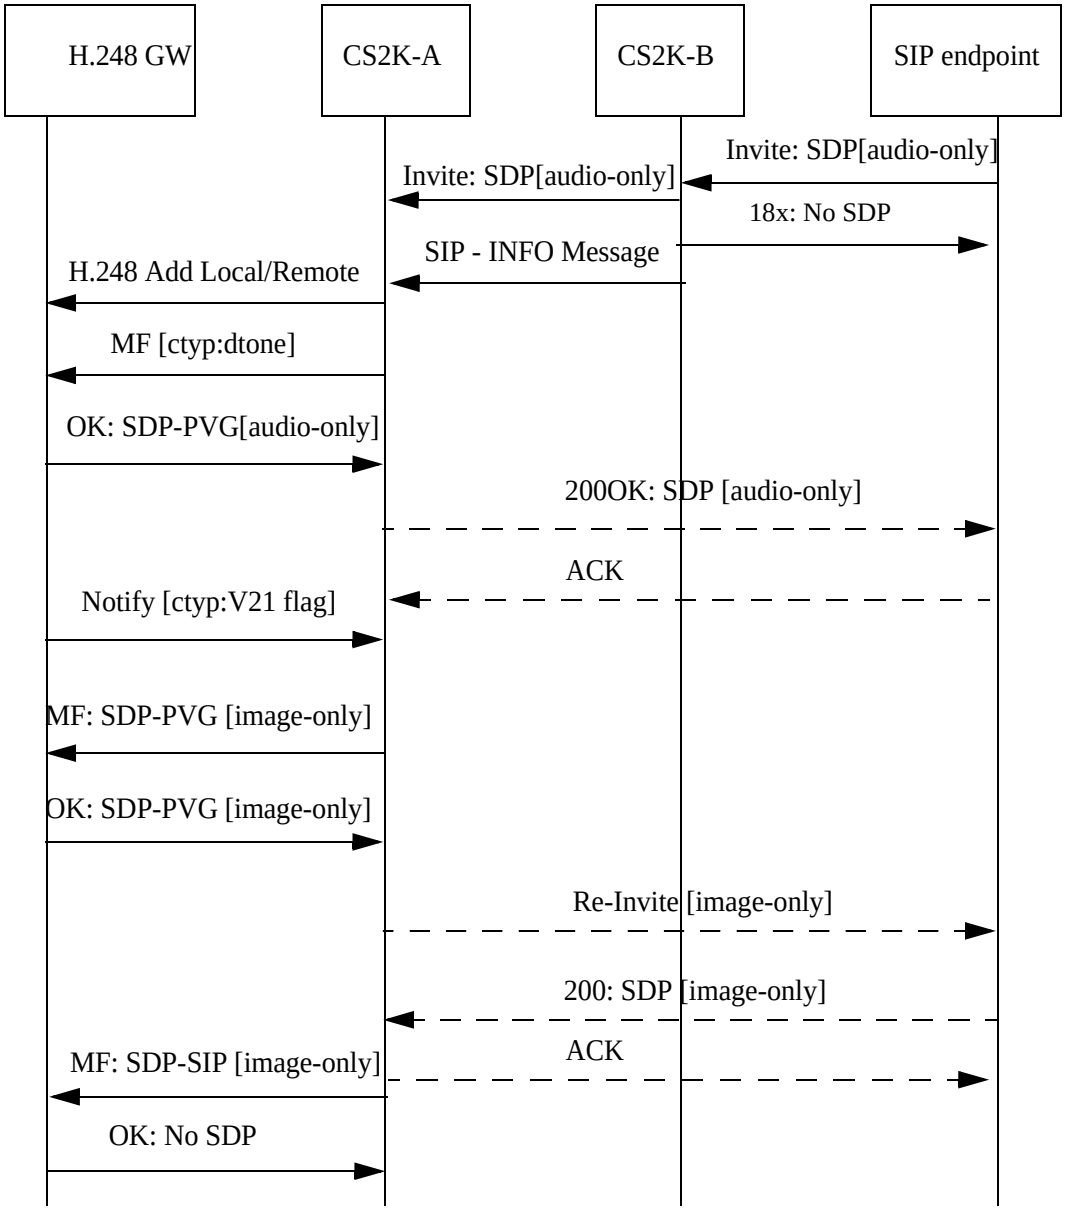
Figure 4 T.38 Calls originating from PVG on CS2K and terminating at CISCO/ MTS



75.2.4.3 Tandeming Support

In this scenario **T.38 Annex D Supported** is enabled in the CS2K-B NGSS, but the call is tandemed to CS2K-A which is not aware that the remote SIP server supports T.38. A SIP INFO message with a proprietary header is used to inform CS2K-A that T.38 support is required causing the CS2K-A to instruct the H.248 PVG to scan for fax tones during the voice call establishment. A voice call is established successfully, and then PVG detects a V.21 flag. V.21 Fax notify is sent from PVG which triggers an attempt to change the codec from G.711 or G.729 to T.38 communicated to the remote end via a re-Invite sequence.

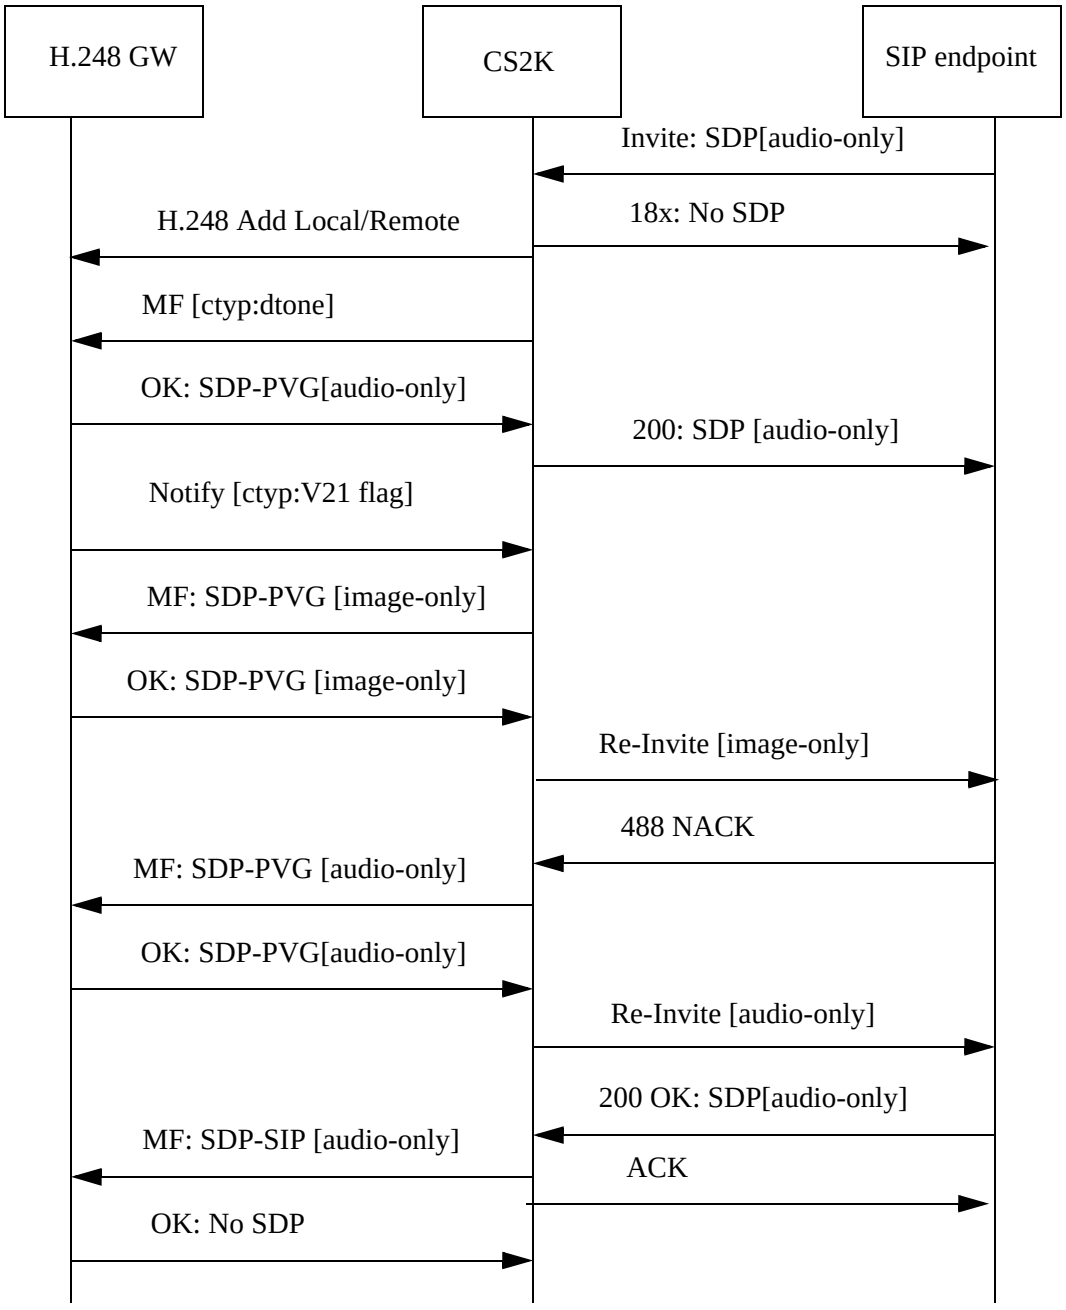
Figure 5 T.38 Fax calls spanning over more than one CS2K



75.2.4.4 Unsuccessful switch attempt, far end rejection.

This scenario describes an unsuccessful T.38 Fax call attempt, where the SIP Re-INVITE for the switch-over from voice to T.38 mode is rejected by a SIP 488 Not Acceptable Here response. In this case an attempt is made to preserve the call by switching back the codec to voice. This is done via another SIP Re-INVITE sequence with voice only codec to switch the call back to voice, as shown in Figure 6.

Figure 6 SIP endpoint rejects the Offer

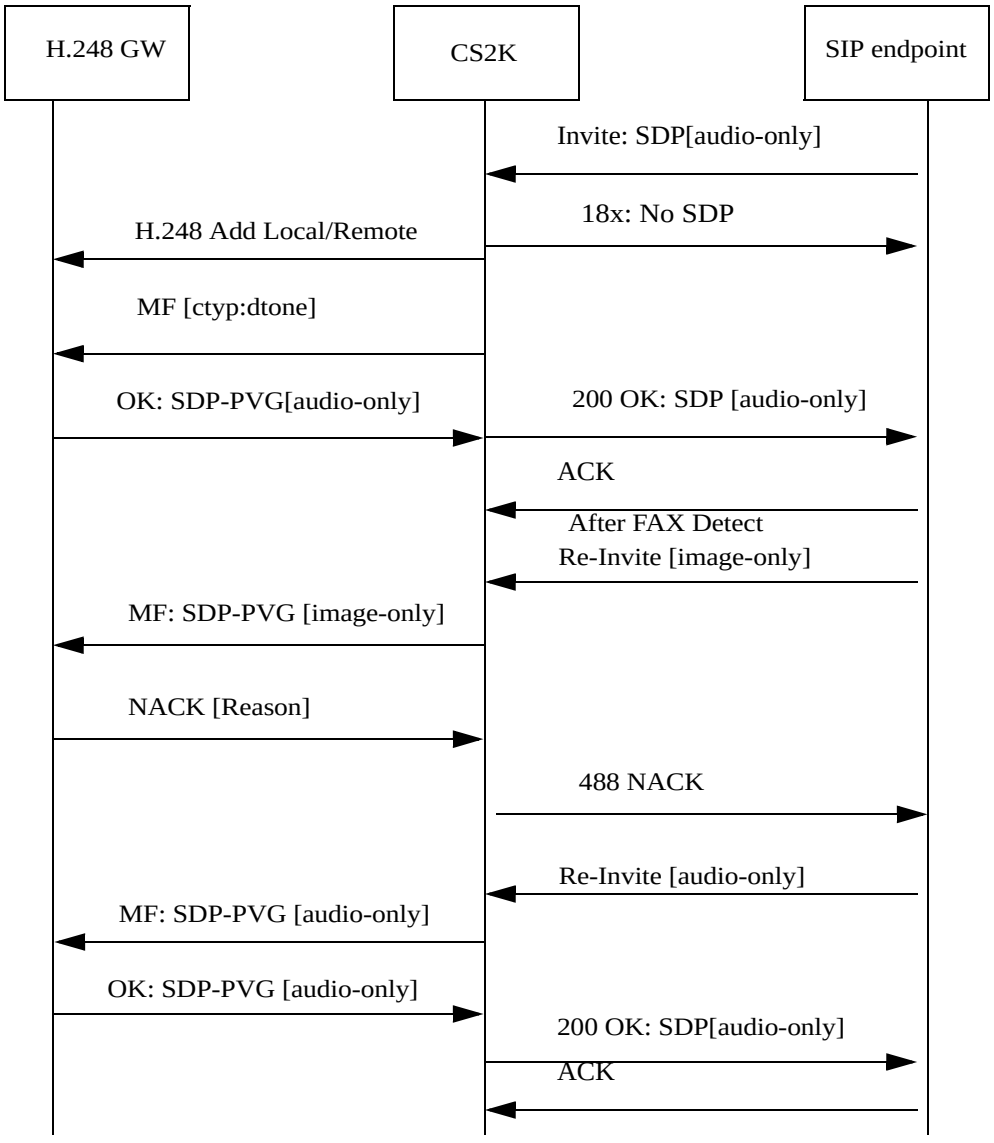


75.2.4.5 Unsuccessful switch attempt, local rejection

When the SIP Re-INVITE Fax offer for a switch to T.38 comes from the remote SIP side and the PVG NACKS it, the PVG sends the reason for the

rejection to the SIP side which in turn sends a SIP Re-INVITE to change the SDPs to audio-only mode.

Figure 7 PVG Rejects Offer



75.3 Hardware Requirements or Dependencies

No New hardware is required.

75.4 Software Requirements or Dependencies

CM/GWC/NGSS: SN09 load

H.248 GW: supporting H.248.1, H.248.2 ctyp package, T.38 mode.

T.38 should be provisioned on the H.248 GWC

T.38 Annex D Supported option should be provisioned on the NGSS Remote SIP Server provisioning page.

75.5 Limitations and restrictions

- This feature verifies T.38 Annex D interworking for H.248 PVG GW on one call leg and 3rd party SIP User Agent Server supporting T.38 Annex D functionality on the other call leg. It should not be enabled for remote SIP servers that don't support T.38 Annex D.
- **Re-Invite for Voice Band Data** field should be only used to prevent auto upspeed on fax detection from G.729 to G.711 by an H.248 PVG that is provisioned to support G.729.

75.6 Interactions

Not Identified.

75.7 Glossary

Term	Description
CED	Called terminal identification answer tone of Fax device (2100 +/- 15 Hz, continuous tone, duration 2.6-4.0 sec.) see T.30 chapter 4.1
CM	Call Manager, Computing Modules
CNG	Calling tone of Fax device (1100 +/- 38 Hz, 0.5 sec. on, 3.0 sec. off, duration 60-120 sec.) see T.30 chapter 4.2.
CS2K	Call Server 2000
G3FE	Group 3 Facsimile Equipment G3FE refers to any entity which presents a communication interface conforming to ITU- T Recommendation T. 30, T. 4, and optionally T. 6. A G3FE may be a traditional G3 facsimile machine, an application with a T. 30 protocol engine or any other possibility mention in the network model for IP Facsimile mentioned in Recommendation T. 38.

Term	Description
GW	Gateway (Signalling Gateway and Media Gateway)
GWC	Gateway Controller
MCS	Multimedia Communication Server
PSTN	Public Switched Telephone Network.
PVG	Passport Packet Voice Gateway
RFC	Request For Comments (IETF)
RTP	Real-time Transport Protocol (IETF 1889, 3550)
SDP	Session Description Protocol (IETF RFC 3266)
SIP	Session Initiation Protocol (IETF RFC 3261)
UDP	User Datagram Protocol (IETF RFC 768)
UDPTL	Facsimile UDP Transport Layer protocol (ITU T.38)
V.21 Preamble	Series of flag sequences 01111110 for 1 sec +/- 15%.

76: Functional description (FN): A00009446

76.1 Feature name and Feature ID

Feature ID: A00009446
Feature name: M2UA/SCTP Protocol for PVG SS7 backhaul support

76.2 Description

This feature implements the M2UA protocol thus providing the USP with the ability to backhaul MTP3 message, allowing the termination of MTP2 or SAAL on a remote node.

The USP always acts as the client with respect to SCTP associations and use SCTP port 2904. The USP implements the ASP portion of the M2UA while the PVG supports the SG portion.

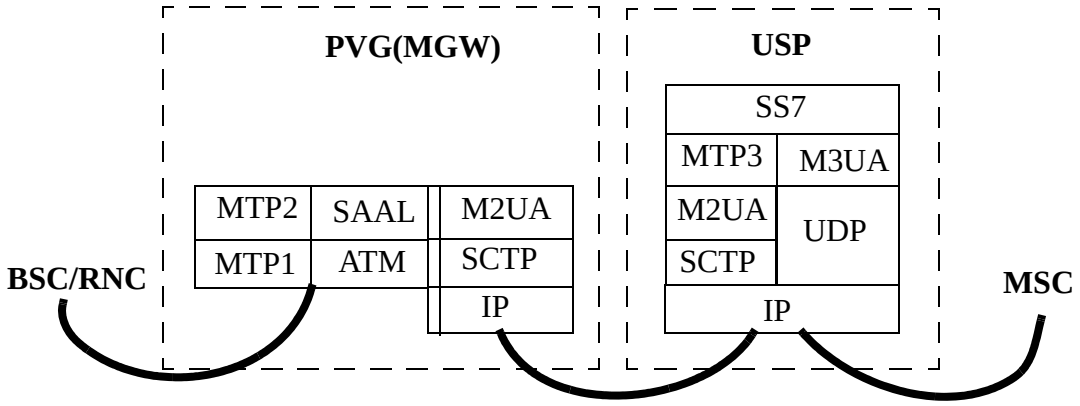
For the requirement, please refer to [2].

76.3 Support M2UA in USP

76.3.1 Functional overview

Broadband SS7 (MTP3b/SAAL/ATM) is the signaling transport used on the UMTS Iu interface, Iu-RANAP from the UTRAN is backhauled to the MSC over IP. The MGW provides the interworking function between bbSS7 and SIGTRAN over IP. The SG/USP accepts the SIGTRAN interface from the MGW and converts it to the proprietary interface required by the MSC.

In addition to the requirement for bbSS7 backhaul, narrowband SS7 (MTP3/MTP2/MTP1) backhaul over IP is also applicable. Narrowband SS7 is used for control signaling on the GSM A interface and ISUP signaling on the PSTN interfaces. Narrowband SS7 is carried over IP in much the same way as bbSS7. MTP2 is terminated on the MGW and transported over M2UA/SCTP/IP to MSC. The enables the MTP2 physical interface to be geographically separated from the MTP3 layer running on the USP.



76.3.2 Function provided by the M2UA Adaptation Layer

76.3.2.1 Mapping

Interface Identifier (IID) is used to tie the SCTP association/stream with the SS7 physical link in the SGP (PVG/MGW). When an ASP (USP) sends an ASP Active message for a particular IID, the SGP will try to provide the Signalling Link Terminal service to an SS7 link tied by the IID.

76.3.2.2 Support for the management of SCTP associations

The M2UA layer may be instructed by local management (LM) to establish an SCTP association to a peer M2UA node. This can be achieved using the MSCTP_ESTABLISH primitive to request, indicate and confirm the etablishment of an SCTP association with a peer M2UA node.

The M2UA layer MAY also need to inform local management of the status of the underlying SCTP associations using the M-SCTP_STATUS request and the indication primitive.

76.3.2.3 SCTP Stream Management

M2UA requires a stream for each ss7 link provisioned. The M2UA layer residing on a card can handle maximum 32 ss7 links. Each association (determined by far-endpoint ip address, local and remote port) can have up to 8 traffic streams and one more stream for management - stream '0' is reserved for ASP Management (ASPM) messages.

The SS7IPLink running M2UA can handle approx 1792 messages/sec at 80% capacity or 2300 messages/sec in overload regardless of message size. The bandwidth of 1792 messages/sec per card is shared among the M2UA links provisioned on that card.

76.3.3 M2UA Message Structure

76.3.3.1 Common Message Header

Table 1: Common Message Header for M2UA

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7

76.3.3.2 M2UA Message Header

For MAUP messages, there is a M2UA specific message header immediately follow the common message header. The format like the below.

Table 4 MAUP Specific Message Header

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7
Tag (0x01)		Length (=8)	
Interface Identifier			

76.3.3.3 Parameters

M2UA messages consist of a Common Header followed by zero or more variable-length parameters, as defined by the message type. The variable-length parameters contained in a message are defined in a Tag-Length-Value format.

The common parameter tags (can be used by all User Adaptation layers) is supported as below.

Table 5: Common Parameters Tags

Value	Description	Notes
1	Interface Identifier (Integer)	
3	Interface Identifier (Text)	Not supported
4	Info String	Not supported
7	Diagnostic Information	Not supported
8	Interface Identifier (Integer Range)	Not supported
9	Heartbeat Data	
11	Traffic Mode Type	
12	Error Code	
13	Status Type/Information	
17	ASP Identifier	
19	Correlation Id	Not supported

Besides the common parameters, there are M2UA specific parameters.

Table 6: M2UA Specific Parameters Tags

Value	Description	Notes

0x2	ACTION_RTRV_MSGS	

76.3.5.7 MAUP - Retrieval Confirm

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7
Tag (0x306)		Length (=8)	
Action (Mandatory)			
Tag (0x308)		Length (=8)	
Result (Mandatory)			
Tag (0x307)		Length (=8)	
Sequence Number (Optional)			

The valid values for Result are shown below.

Value	Define	Note
0x1	RESULT_SUCCESS	
0x2	RESULT_FAILURE	

76.3.5.8 MAUP - Retrieve Indication

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7
Tag (0x300)		Length (=8)	
Protocol Data			

The Retrieval Indication message is sent by the Signalling Gateway with a PDU from the transmit or retransmit queue. The Retrieval Indication message does not contain the Action or Sequence Number fields, just a MTP3 Protocol Data Unit (PDU) from the transmit or retransmit queue.

76.3.5.9 MAUP - Retrieve Complete Indication

The MTP2 Retrieval Complete Indication message is exactly the same as the MTP2 Retrieval Indication message except that it also indicates that retrieval is complete. In addition, it MAY contain a PDU (which MUST be the last PDU) from the transmit or retransmit queue.

76.3.5.10 MAUP - Congestion Indication

The Congestion Indication message can be sent from a Signalling Gateway Process to an ASP to indicate the congestion status and discard status of a SS7 link.

0	1	2	3

0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7
Tag (0x304)		Length (=8)	
Congestion Status (Mandatory)			
Tag (0x308)		Length (=8)	
Discard Status (Optional)			

For the Congestion Status, there are the following values can be selected.

Value	Define	Note
0x0	LEVEL_NONE	
0x1	LEVEL_1	Not supported
0x2	LEVEL_2	Not supported
0x3	LEVEL_3	

76.3.5.11 ASPM - ASP UP

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7
Tag (0x11)		Length (=8)	
ASP Idenfifier (optional)			
Tag (0x4)		Length (=8)	
Info String (optional)			

The optional ASP Identifier parameter would contain a unique value that is locally significant among the ASPs that support an AS. The SGP should save the ASP Identifier to be used, if necessary, with the Notify message.

76.3.5.12 ASPM - ASP UP Ack

0	1	2	3
0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7	0 1 2 3 4 5 6 7

76.6 Provisioning

76.6.1 Provisioning - CLI interface

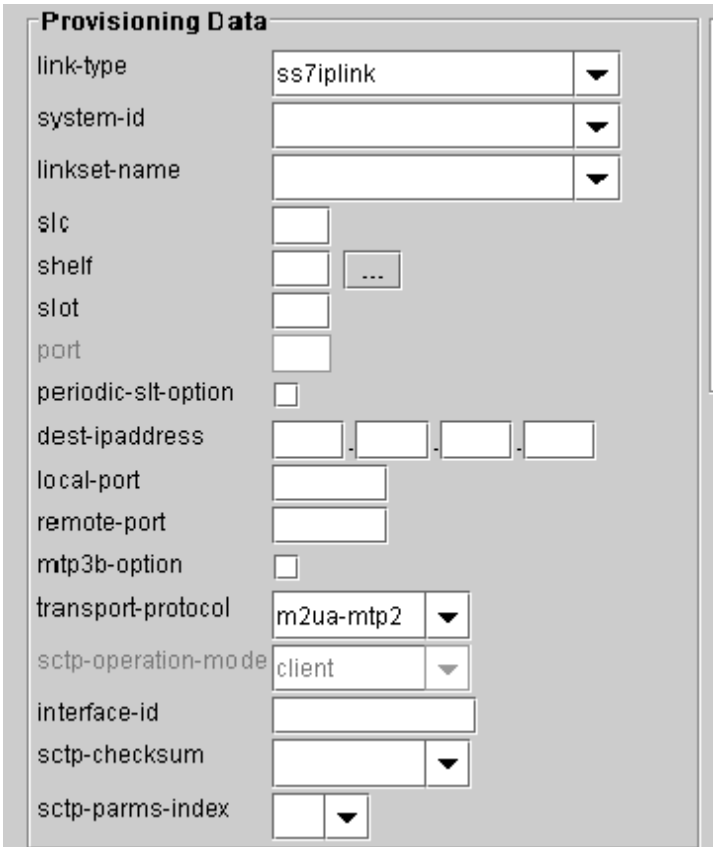
CMD: mtp link add <linkset-name> <slc> ss7iplink <shelf> <slot> <periodic-slt-option> <dest-ipaddr> <local-port> <remote-port> { m2ua client <sctp-checksum> <sctp-parm-index> | m2ua <interface-id> <sctp-checksum> <sctp-parm-index> }

CMD: mtp link mod <linkset-name> <slc> ss7iplink interface-id <interface-id>

CMD: mtp link mod <linkset-name> <slc> ss7iplink transport-protocol { m2ua client <sctp-checksum> | m2ua <interface-id> <sctp-checksum> }

CMD: mtp link show <linkset-name> <slc>

76.6.2 GUI



Some fileds are needed to be noticed when protocol M2UA is selected.

Field Name	Value	Description
transport-protocol	m2ua-mtp2/ m2ua-saal	select different value depending on the far-end l2 type in the PVG/MGC
local-port	2904	2904 is dedicated for M2UA
remote-port	2904	2904 is dedicated for M2UA

76.7 Hardware Requirements or Dependencies

N/A

76.8 Software Requirements or Dependencies

N/A

76.9 Limitations and restrictions

1. USP can only be configured as SCTP Client

2. The M2UA layer supports a n+k redundancy model(active-standby, load sharing, broadcast) where n is the minimum number of redundant ASPs required to handle traffic and k ASPs are available to take over for a failed or unavailable ASP. A simplex 1+0 model is also supported as a subset, with no ASP redundancy is supported by the feature. (ASP identifier <-> number of ASP, link(set) <-> ASP), (send it PVG team)

3. Registration procedure is not supported by the feature.

76.10 Interactions

N/A

76.11 Glossary

SCTP	Stream Control Transmission Protocol
SG	Signaling Gateway

76.12 Reference

1. RFC3331 Signaling System 7 (SS7) Message Transfer Part 2 (MTP2) - User Adaptation Layer

77: Functional description (FN): A00009463

77.1 Feature name and Feature ID

Core and Billing Manager (CBM) to support the Centralized user Authentication, Authorization, and Administration, with Integrated Element Management System (IEMS) - A00009463.

77.2 Description

This feature provides the CBM capability to support Centralized Authentication, Authorization, Administration (AAA) with the Integrated Element Management System (IEMS). This feature activates PAM, RADIUS, PAM-MKHOMEDIR, NSS-SAML and SAML modules to enable integration of CBM with the IEMS and SAML, in order to allow the use of Centralized AAA.

This feature is the equivalent of the SN08 A00007489 which provided similar capability on the SDM product, with the exception of the following points:

- There is neither the support nor the introduction of any new user group on the CBM as part of this feature (not included in SN09 features).
- There is no new security or audit log generated by this feature.
- In addition to the SSH, there are other applications (e.g. login, su, etc.) that are supported on the CBM. The ProFTP and SFT (for CM->CBM Secure FTP) are however not supported.

Note: The details of the above-mentioned equivalent SDM feature is found in PLS fmdoc library under A00007489.aa14 design documents.

With respect to AAA functionality, there are two possible configurations supported by the CBM, which are described in this document, and captured in the following figures:

Figure 1 CBM with central security server configuration & components

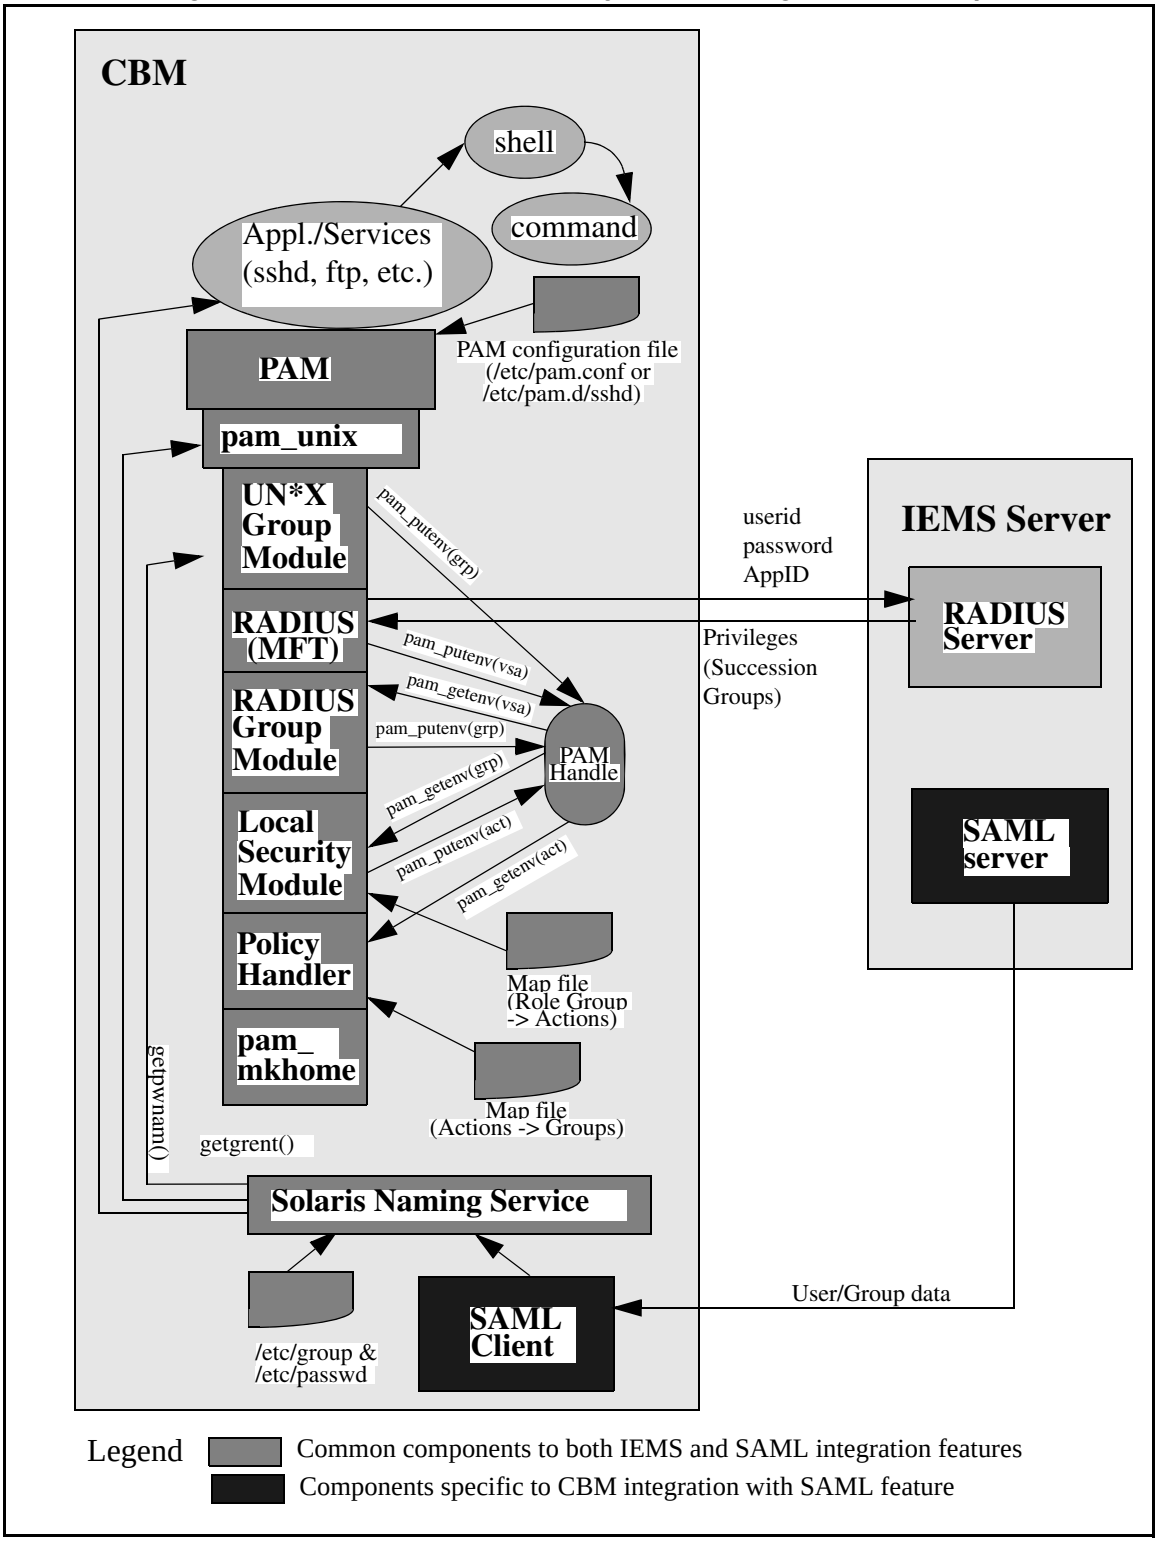

Figure 2 CBM Standalone (i.e. without central security server) config. & components

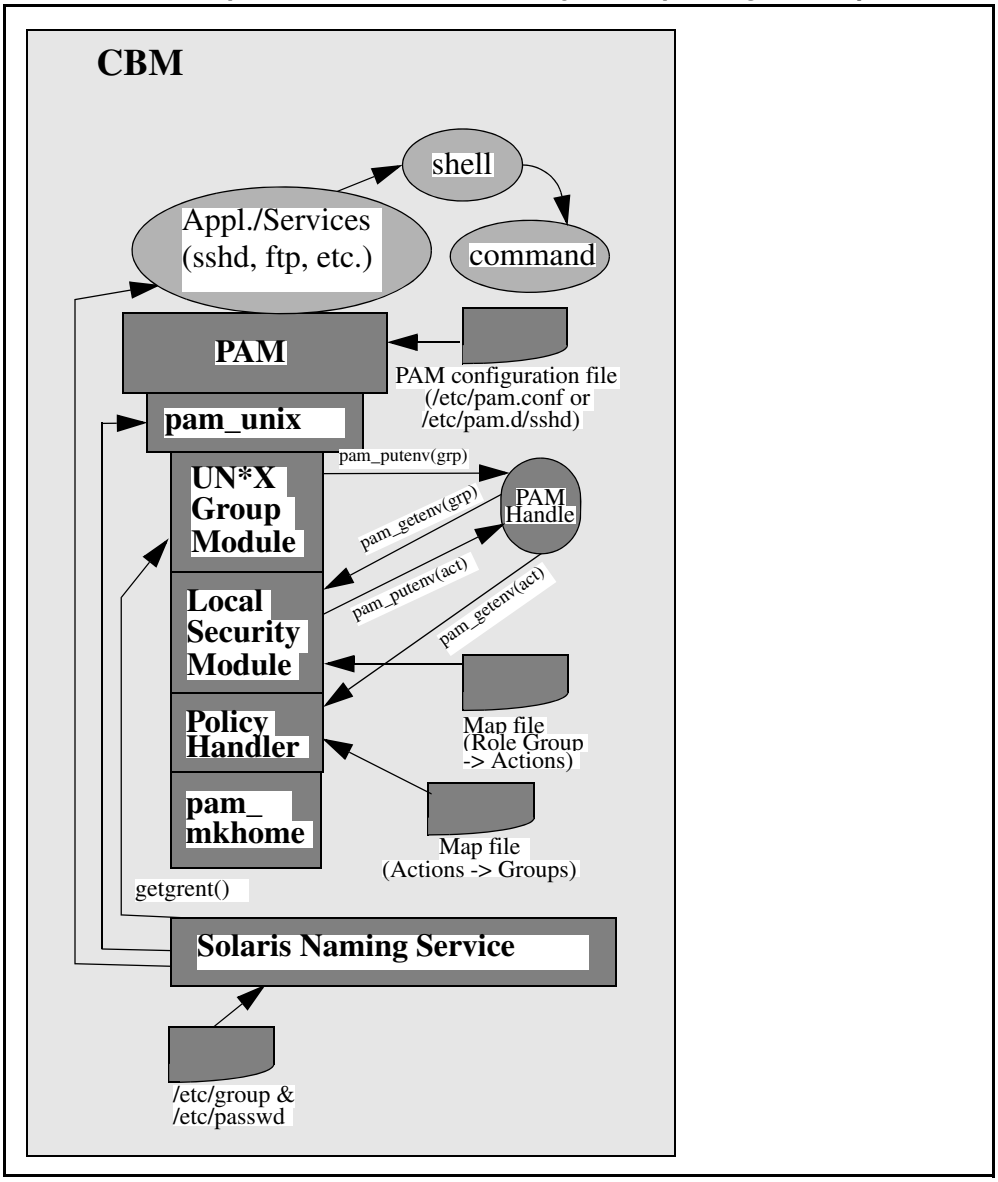
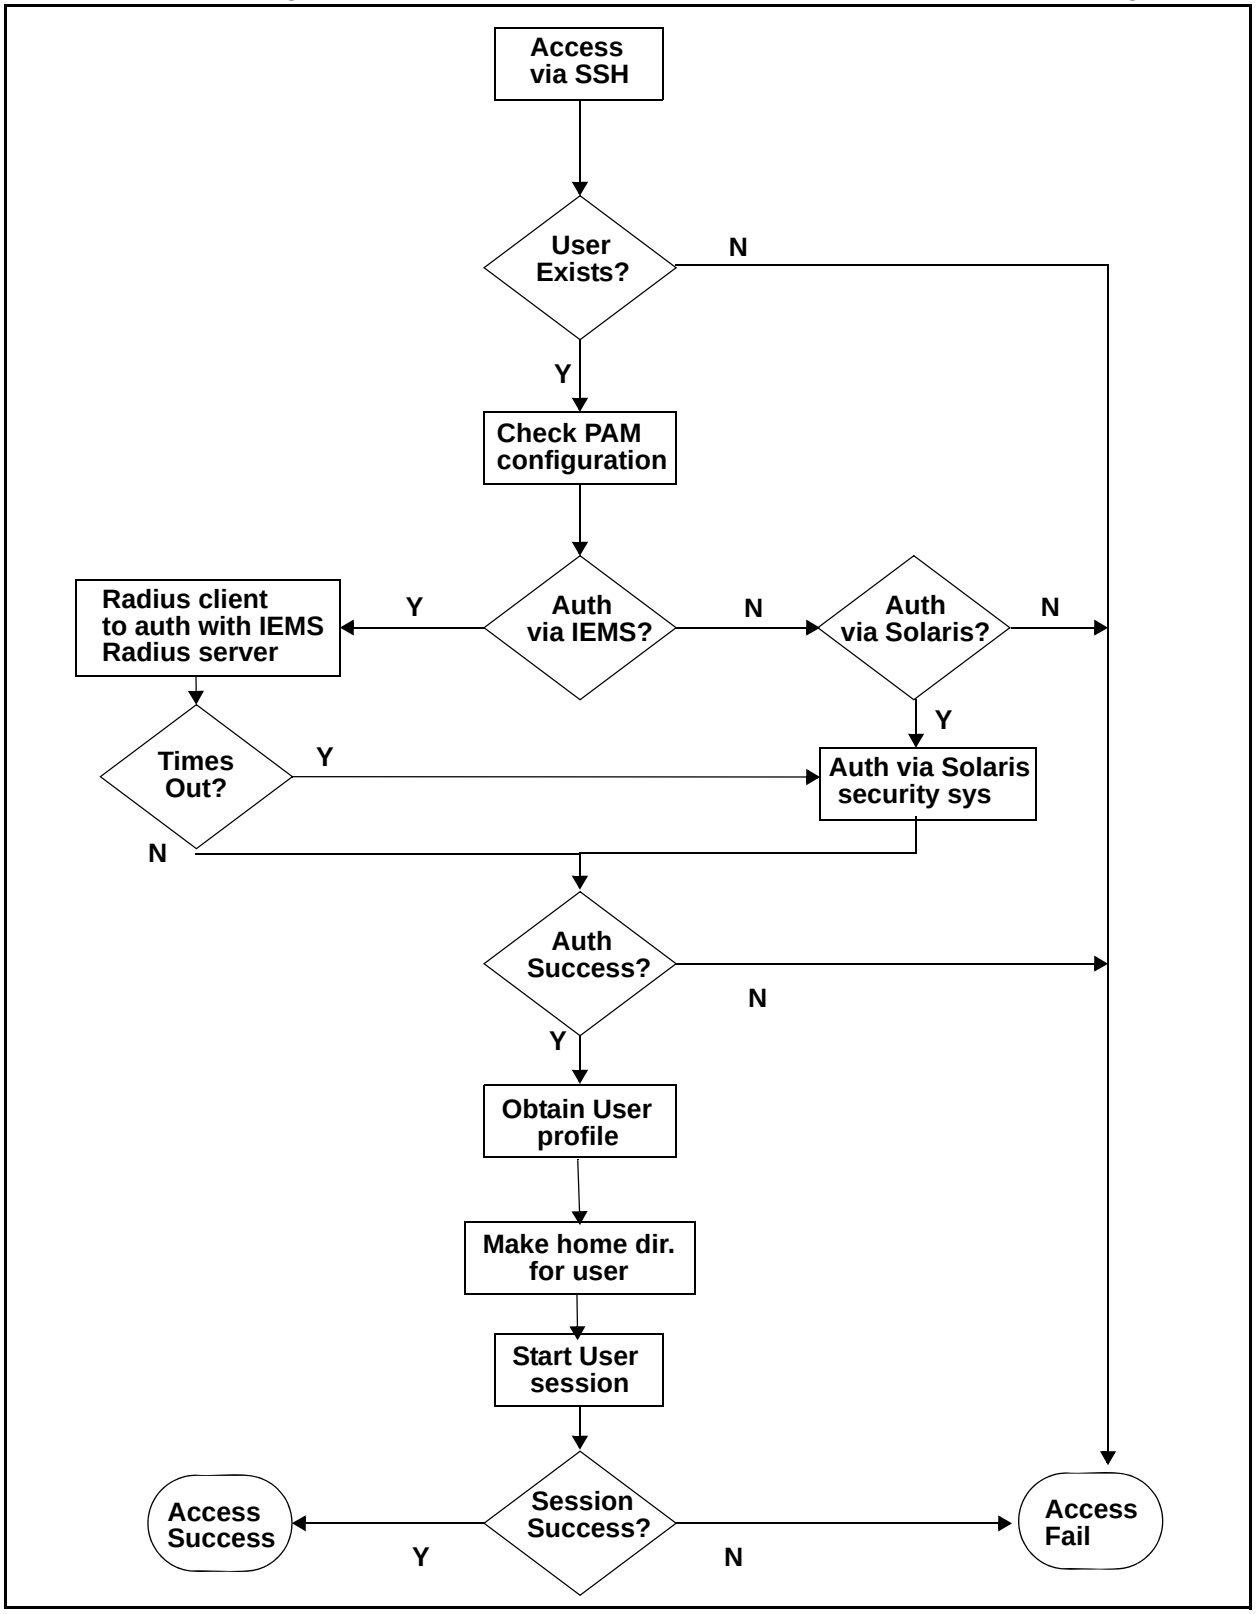


The following is a flow chart for user authentication and authorization through SSH.

Figure 3 Flow chart for user authentication and authorization through SSH



77.3 Hardware Requirements or Dependencies

No new hardware dependency is introduced in this feature for the Standalone CBM deployment (i.e. without centralized security server). For the CBM deployment with IEMS centralized security server, the IEMS and its hardware dependencies are required by this feature.

77.4 Software Requirements or Dependencies

The PAM, RADIUS and SAML software are required on the CBM. Also, for the CBM deployment with IEMS centralized security server, IEMS and its software dependencies are needed by this feature.

77.5 Limitations and restrictions

TBD

77.6 Interactions

Changes to Network Connectivity Applications

The following table shows the impact of this feature to network connectivity applications.

Table 1 Network Connectivity Applications

Application	Current Release	SN09	Configurable - i.e. Turn On/Off (Y/N)	Support IEMS central security server (Y/N)
SSH (with password)	Enable	Enable	N	Y
SFTP (with password)	Enable	Enable	N	Y
SSH (with key)	Enable	Enable	N	N
SFTP (with key)	Enable	Enable	N	N
Telnet	Enable	Enable	N	Y
FTP	Enable	Enable	N	Y
Console access	Enable	Enable	N	Y
su	Enable	Enable	N	Y
ProFTP	Disable	Disable	N	N
SFT (FTP Proxy)	Enable	Enable	N	N

Note: It is recommended that Telnet and FTP applications should not be used since SSH and SFTP are more secure tools.

When an application/service is not integrated to work with a central security server, the service can only permit access to users who have accounts locally on the CBM.

77.7 Glossary

Term	Description
AAA	Authentication, Authorization, Accounting
CBM	Core and Billing Manager
CUA	Centralized User Administration
IEMS	Integrated Element Manager System
PAM	Pluggable Authentication Module
SAML	Security Assertion Markup Language
SDM	SuperNode Data Manager
VSA	Vendor Specific Attributes

78: Functional description (FN): A00009470

78.1 Feature name and Feature ID

SuperNode Data Manager (SDM) to support Security Assertion Markup Language (SAML) NSSwitch client - A00009470.

78.2 Description

This feature will add SAML NSSwitch client function on SDM to integrate with centralized IEMS's (SS 1.1) SAML server.

This SN09 feature is to enhance the existing SDM security functionality which were developed in SN08. It will improve SDM centralized AAA function through IEMS by removing the need to update user accounts on SDMs whenever an SDM user is added/deleted/modified on IEMS.

> ***Note:*** Please refer to SN08 IEMS Integration feature document in PLS FMDOC (a00007489) for detail information on SN08 functionality.

In SN08, SDM only provides access to the user attributes (identification) information in local /etc files. It does not support other naming/identification information sources for the user attributes. As a result, when an SDM user account is created on IEMS, the user account also needs to be added on each SDM via an SDM script (enableIEMSUser). When an SDM user account is deleted on IEMS, the user account also needs to be removed on each SDM via an SDM script (disableIEMSUser).

This SN09 feature will address this limitation by providing SAML (Security Assertion Markup Language) client on SDM for user information retrieval. This will allow IEMS centralized security server to be one of the naming/identification information sources for the user attributes. There will be no need to maintain the local /etc files with enableIEMSUser and disableIEMSUser scripts whenever an SDM user is /added/modified/deleted on an IEMS server.

78.3 Hardware Requirements or Dependencies

No new hardware dependency is introduced in this feature for Standalone SDM deployment without centralized security server.

For SDM deployment with IEMS centralized security server, IEMS and its hardware dependencies are needed by this feature.

78.4 Software Requirements or Dependencies

For SDM deployment with IEMS centralized security server, IEMS and its software dependencies are needed by this feature.

This feature has included the following dependency software for SAML client:

- curl
- log4cpp
- Xerces-c
- xml_security_c
- OpenSAML

Please refer to 1.11 “License” in DID section for detail on third party software and their copyright notices.

78.5 Limitations and restrictions

- Authentication: This feature doesn’t change the existing authentication method for IEMS users. The users on the IEMS server will remain being authenticated by SDM through PAM, which in turn uses RADIUS protocol to authenticate IEMS users.
- SDMMTC User level can only be used to change user/group attributes when an SDM is configured to use local security server. When IEMS central security server is configured for the SDM, IEMS Security Administration GUI must be used to update the user/group information.
- Password update: This feature doesn’t provide IEMS users to change password from an SDM. The IEMS Security Administration GUI is still the tool for this purpose.
- Account and password status: An IEMS user will not get expiration warning when she/he logs into SDM. However, since the authentication is done through RADIUS, an IEMS user with an expired account and/or password will not be allowed to log into SDM because the RADIUS server will fail the login attempt.

78.6 Interactions

No new interaction is introduced by this feature,

79: Functional description (FN): A00009508

79.1 Feature name and Feature ID

A00009508: Automatic Message Accounting Session Initiation Protocol (SIP) Line Identification

79.2 Description

Feature A00009508 introduces the new AMA billing Module 260 which captures originating and terminating agent component and protocol information for packet network agents. Module 260 contains two fields: Table 620 captures the connection side and component type. Table 622 captures the protocol type used. Module 620 is outlined below with current table values:

Module Code 260 - IP/Packet Party Identification (Vendor Specific)

Module Code	88	2	0
Component Type	620	4	1
IP Service Protocol	622	4	3
		Total	5

Table 620, Component Role (NDGR)
Chars Meaning
1: Connection Side (default = 0)
1 = Originating
2 = Terminating
2-3: Component Type
01 = Customer Premise Equipment
02 = Network Edge Component
03 = Gateway System
99 = Unspecified
4: SIGN (hex-C)

Table 622 - IP Service Protocol (Vendor Specific)
Chars Meaning
1: Reserved (default = 0)
2-3: Protocol Type
00 = unspecified
01 = SIP
02 = SIP-T
03 = SIP-I
04 = H.323 v1
05 = H323.v2
06 = H.248/MEGACO
07 = MGCP
4: SIGN (hex-C)

Feature A00009508 provides the framework to capture all variants; however, only the capturing of SIP lines client information is provided by this feature. This feature complements the OAM&P core development done under A00008556 by providing identification of SIP lines for billable calls. The following are sample records illustrating SIP line party information capture:

```
*HEX ID:AA  STRUCTURE CODE:40625C  CALL CODE:110C  SENSOR TYPE:036C

IP SERVICE PROTOCOL:001C  MODULE CODE:000C
```

For the above examples, the Call Code 110 originating Equal Access AMA record contains a Module 260 which shows that a SIP client at the customer's premise originated the call. Component Role value of 101 can be broken into (1) originating and (01) customer premise equipment. IP Service Protocol shows SIP (01) being used. The Call Code 119 terminating Equal Access AMA record contains a Module 260 that shows the call terminated to a SIP client. Component Role value 201 can be broken into (2) terminating and (01) customer premise equipment.

Feature A00009508 uses a new tuple in table AMAOPTS to activate and deactivate Module 260 inclusion. The new OPTION is called RECORD_MC260, and the SCHEDULE will be either ON or OFF. The default setting is OFF. The new option activates recording of packet client involvement for both originating and terminating agents. This option does not force billing; it collects the additional information for existing billable scenarios.

The following CI session shows how feature functionality is activated. Deactivation is achieved by setting schedule back to OFF.

```
>table amaopts
JOURNAL FILE UNAVAILABLE - DMOS NOT ALLOWED
TABLE: AMAOPTS
>pos RECORD_MC260
        RECORD_MC260                    OFF
>lis
           OPTION                   SCHEDULE
-----------------------------------------------------------
        RECORD_MC260                    OFF
>cha
```

```
JOURNAL FILE UNAVAILABLE - DMOS NOT ALLOWED
ENTER Y TO CONTINUE PROCESSING OR N TO QUIT
>y
AMASEL: OFF
>on
TUPLE TO BE CHANGED:
        RECORD_MC260                    ON
ENTER Y TO CONFIRM, N TO REJECT OR E TO EDIT.
>y
TUPLE CHANGED
JOURNAL FILE INACTIVE
```

On the SDM/CBM Side:

This feature A00009508 introduces the new AMA Module Code 260 with two new fileds COMPONENT ROLE and IP SERVICE PROTOCOL to the BAF database on SDM/CBM.

The new Module 260 with the two new fileds and its definitions are added to baf.db file (BAF database) to be supported by AMADUMP tool on SDM/ CBM.

Definition of the two new fields added in baf.db are:

```
COMPONENT_ROLE 16 4 bcd 0 COMPONENT_ROLE
COMPONENT ROLE

IP_SERVICE_PROTOCOL 16 4 bcd  1 IP_SERVICE_PROTOCOL
IP SERVICE PROTOCOL
```

And the following is the complete module code defined in baf.db:

```
[Subrecord]
260
MODULE_CODE_ID
COMPONENT_ROLE
IP_SERVICE_PROTOCOL
[^]
```

This functionality could be verified using AMADUMP tool by executing the following steps:

Login to SDM or CBM as root user or maint user

Execute the listfile command for AMA stream to get the filename(s)

billmtc; filesys; listfile ama

Execute amadump command to display the billing file with module code 260

billmtc; tools; amadump ama

AMADUMP>> dump details sum fname <file- name>

Where <file-name> is from the output of listfile command.

The following is the AMADUMP output of a billing file with Module Code 260 on SDM/CBM:

```

79.3 Hardware Requirements or Dependencies

There are no hardware dependencies for this feature.

79.4 Software Requirements or Dependencies

Since feature A00009508 changes AMA, display and downstream utilities need to be adjusted to handle the new information now present. This feature addresses all core required changes and SDM required changes to support this new module code; however, all downstream processing programs need to be updated as well.

79.5 Limitations and restrictions

There are no restrictions.

79.6 Interactions

Feature A00008556 introduces the DPL LGRP type and DPL line option. DPL is used to denote SIP lines' components in the core. This designation is also used by this feature in determining if an agent is a SIP line.

79.7 Glossary

Term	Description
AMA	Automatic Message Accounting
DPL	Dynamic Packet Line
EA	Equal Access
LGRP	Logical Group: Used to group Succession agents
SDM	Supernode Data Manager
SIP	Session Initiation Protocol
RECORD_MC260	New AMAOPTs OPTION which controls A00009508 functionality.
AMADUMP	AMADUMP is a tool, which displays the billing records from AMADNS or DIRP billing files stored on SDM.

80: Functional description (FN): A00009513

80.1 Feature name and Feature ID

A00009513 PMA for SIP Lines

80.2 Description

The PMA for SIP Lines feature extends support for the existing Packet Media Anchor (PMA) for Dynamic Packet Trunks (DPTs) to SIP Lines. SIP Lines use the PMA to access CS2k based features that require the collection of additional digits. These features include:

North America

- Call Forward Programming
- Call Screening Override
- AIN collect info
- Speed Dial Programming
- Subscriber Activated Call Blocking
- Direct Inward System Access
- Call Forward Remote Activation

International

- IBN Call Forward Programming
- Call Screening Override
- Speed Dial Programming
- Subscriber Activated Call Blocking
- Last Number Redial
- Anonymous Call Rejection
- IBN CFU/CFB/CFD intragroup / intergroup screening
- IBN Do Not Disturb

The PMA will be removed from the bearer path of SIP lines once it is no longer required by the feature which inserted it.

80.3 Hardware Requirements or Dependencies

This feature adds no new hardware dependencies to the system. The feature does have all the dependencies of the features it builds on. Please reference the feature documentation for A00007120 PMA dependencies and reference A00008234 for SIP Lines dependencies.

80.4 Software Requirements or Dependencies

This feature adds no new software dependencies to the system. The feature does have all the dependencies of the features it builds on. Please reference the feature documentation for A00007120 PMA dependencies and reference A00008234 for SIP Lines dependencies.

80.5 Limitations and restrictions

This feature adds no new limitations or restrictions to the system. The feature does have all the limitations and restrictions of the features it builds on. Please reference the feature documentation for A00007120 PMA dependencies and reference A00008234 for SIP Lines dependencies.

80.6 Interactions

The PMA for SIP Lines feature uses the existing Media Anchor (MA) pools to access the MA resources on the CS2k system. Since a connection through the MA can only be used by one SIP Line or DPT at a time the PktMA resource pool must be sized to support both functions in the system.

80.7 Glossary

Term	Description
DPT	Dynamic Packet Trunk
MA	Media Anchor
PktMA	Packet Media Anchor
PMA	Packet Media Anchor

81: Functional Description (FN): A00009514

81.1 Feature name and Feature ID

CS2K-MCS Interop for SN09

Feature ID: A00009514

81.2 Description

SIP on Succession Communication Server was first introduced in SN03 to enable Communication Server - Communication Server and Communication Server -MCS5200 communication. At the time of implementation, the IETF SIP/SIP-T standards were still at pre-RFC stage. Nortel being the pioneer has moved forward with its implementation and has gained vast experience in SIP-T interop in the past few years. In the meantime the IETF specifications have evolved and matured. Communication Server initial implementation was based on the GWC/VRDN architecture which has imposed few limitations on the overall application. In SN07, with the introduction of the Session Server, the SIP-T/SIP implementation on the Succession Communication Server has been revamped and evolved to an IETF compliant open interface. The Session Server is a high capacity carrier grade new platform consisting of hardware based on SAM-XTS and software consisting of base and share layers. The application introduced on this platform in SN07 was the SIP Gateway allowing interop between the Communication Server and 3rd party Call Servers and Application Servers. The Session Server enhances the capability of the Succession Communication Server which is critical in Nortel's strategic market positioning in VoIP solutions.

This feature provides support for SN09 NGSS interworking with MCS release 09 (a.k.a. MCS 4.1) and will also provide support for the backward compatibilty with MCS 3.0. SN09 NGSS interworking with MCS 4.0 will not be supported. This feature will address upgrade scenarios, new content integration, and regression testing. One of the new pieces of functionality is the support for private/public name delivery for Converged Desktop users, which includes the support for SIP phone-context tag fields.

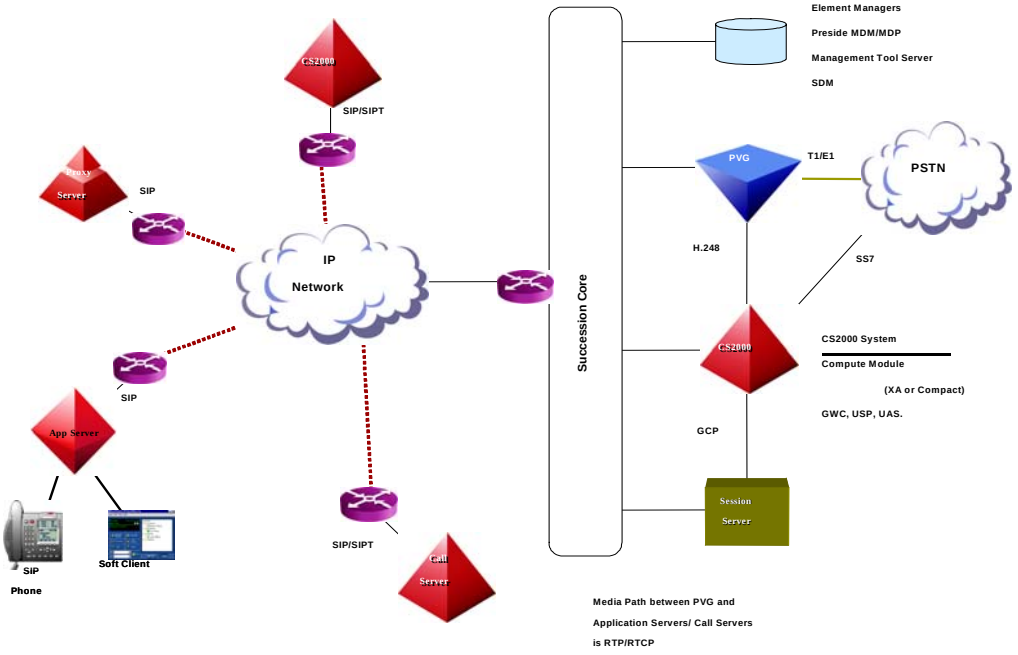

Figure-1 CS2K Network Configuration

81.2.1 Upgrade

The following table shows support for the interworking configuration of the CS2K and MCS releases.

Table 1: CS2K and MCS Releases Support

MCS	MCS 3.0	MCS 4.0	MCS 4.1
(I)SN07	Supported	Not Supported	Not Supported
(I)SN08	Supported	Supported	Supported
(I)SN09	**Supported ***	**Not Supported**	**Supported**

* Still under consideration

After any upgrade either on the CS2K side or on the MCS side the upgraded configuration must comply to the supported configuration. The following shows the CS2K configuration with the MCS.

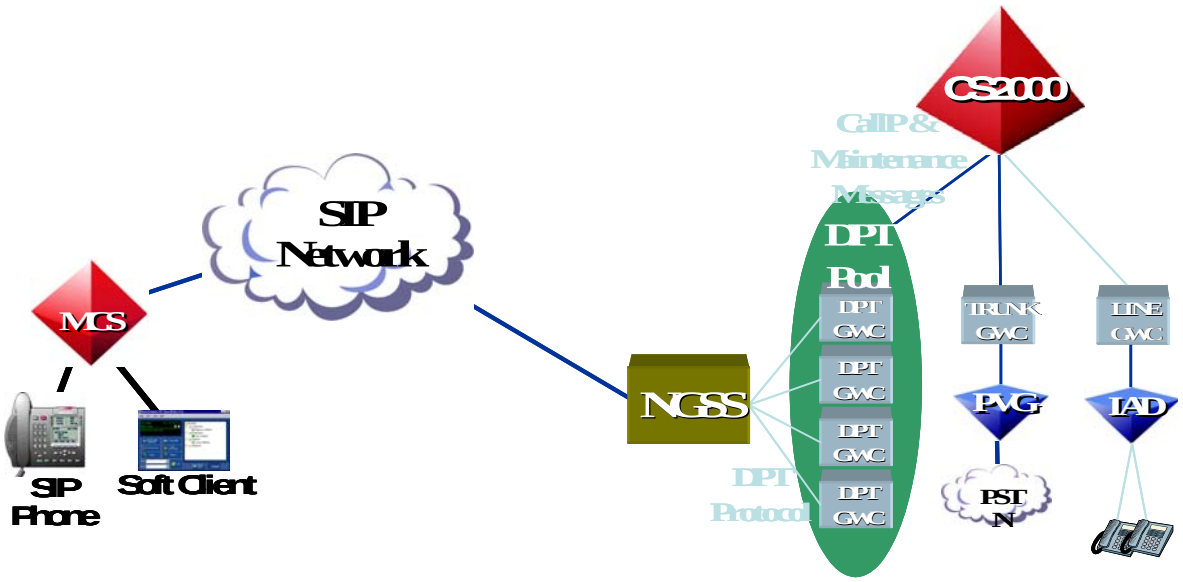

Figure-2 NGSS - MCS Interworking Configuration

The following walks through the different configuration scenarios and procedure which should be followed to upgrade the NGSS to the SN09 release.

81.2.1.1 SN07 or SN08 CS2K with VRDN Interworking with MCS 3.0

In this configuration the VRDN must be first migrated to the NGSS architecture prior to the CS2K upgrade. After the VRDN to NGSS migration CS2K components including NGSS should then upgraded to the SN09 software release. Depending on the customer requirement the MCS can either be left at MCS 3.0 or could be upgraded to MCS 4.1. MCS should not be, however, upgraded to MCS 4.0.

81.2.1.2 SN07 or SN08 CS2K with NGSS Interworking with MCS 3.0

In this configuration the CS2K components including NGSS could be directly upgraded to SN09 software release. Depending on the customer requirement the MCS can either be left at MCS 3.0 or could be upgraded to MCS 4.1. MCS should not be, however, upgraded to MCS 4.0.

81.2.1.3 SN07 CS2K with either VRDN or NGSS Interworking with MCS 4.0 or MCS 4.1 - This configuration is not supported

81.2.1.4 SN08 CS2K with VRDN Interworking with MCS 4.0

In this configuration the MCS must be first upgraded from MCS 4.0 to MCS 4.1 and the VRDN must be migrated to the NGSS architecture prior to the CS2K upgrade. When the MCS upgrade and the migration from the VRDN to NGSS has been completed then the CS2K components including NGSS could be upgraded to SN09 software release.

81.2.1.5 SN08 CS2K with NGSS Interworking with MCS 4.0

In this configuration the MCS must be first upgraded from MCS 4.0 to MCS 4.1 prior to the CS2K upgrade. When the MCS upgrade has been completed then the CS2K components including NGSS could be upgraded to SN09 software release.

81.2.1.6 SN08 CS2K with VRDN Interworking with MCS 4.1

In this configuration the VRDN must be first migrated to the NGSS architecture prior to the CS2K upgrade. When the migration from the VRDN to NGSS has been completed then the CS2K components including NGSS could be upgraded to SN09 software release.

81.2.1.7 SN08 CS2K with NGSS Interworking with MCS 4.1

In this configuration the CS2K components including NGSS could be directly upgraded to SN09 software release.

81.2.1.8 SN09 CS2K with VRDN - This configuartion is not supported because VRDN is not supported on SN09

81.2.1.9 SN09 CS2K with NGSS Interworking with MCS 3.0

Depending on the customer requirement the MCS can either be left at MCS 3.0 or could be upgraded to MCS 4.1. MCS should not be, however, upgraded to MCS 4.0.

81.2.2 GUI Support

This section describes how to access and data fill the Nature of Address/ Numbering Plan Indicator to Phone Context (NOA/NPI/PC) and Out of Band DTMF Payload portions of the Succession Communication Server 2000 Session Server Manager Graphic User Interface (GUI).

81.2.2.1 NOA/NPI/PC section access

Once logged in and accessed the Succession Communication Server 2000 Session Server Manager link, select Provisioning -> Application -> SIP Gateway to display the NOA/NPI/PC section menu option.

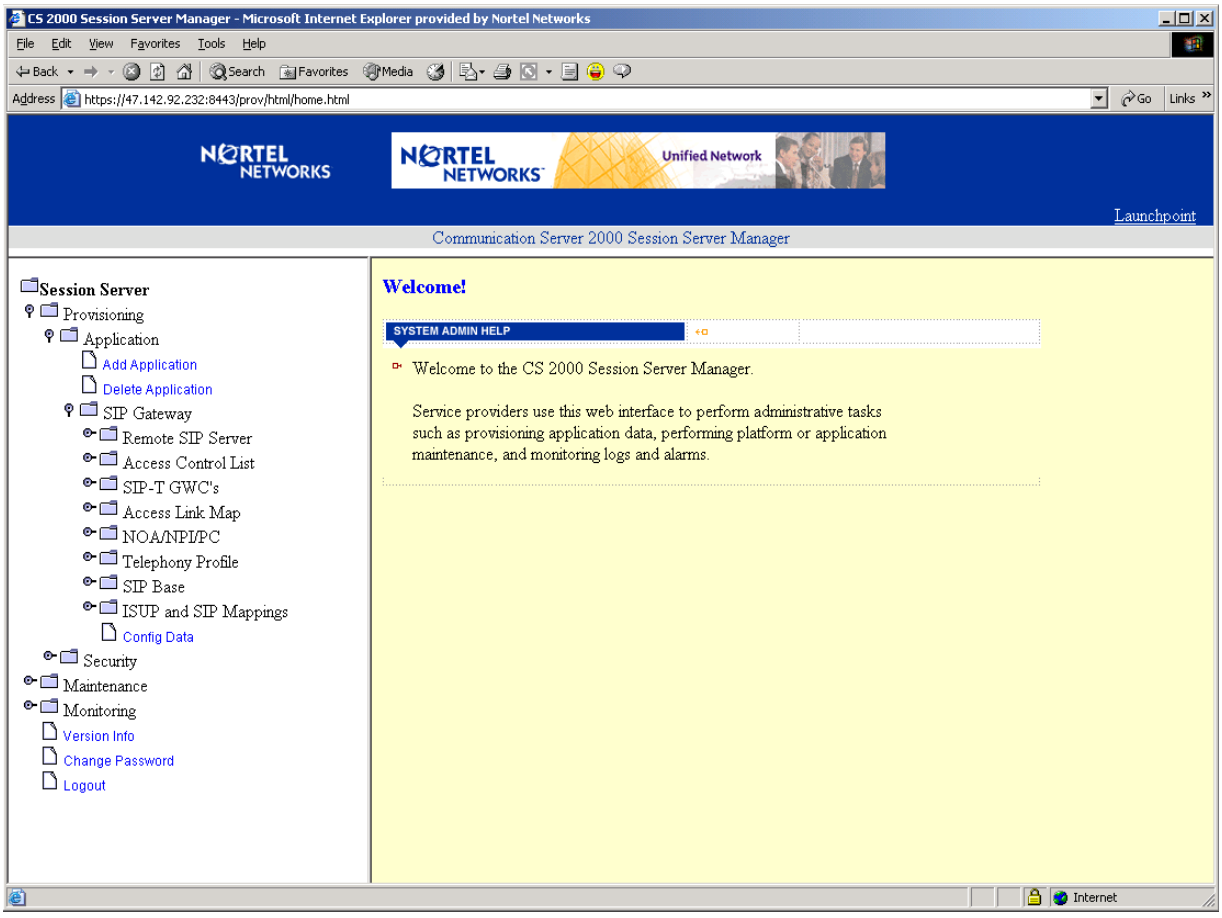

Figure 1 NOA/NPI/PC section access

81.2.2.2 Add/Listing NOA's

Select NOA/NPI/PC menu option to display the Add NOA, List NOA and NOA/NPI/PC Mapping menu options. Select List NOA menu option to view the default list of NOA's.

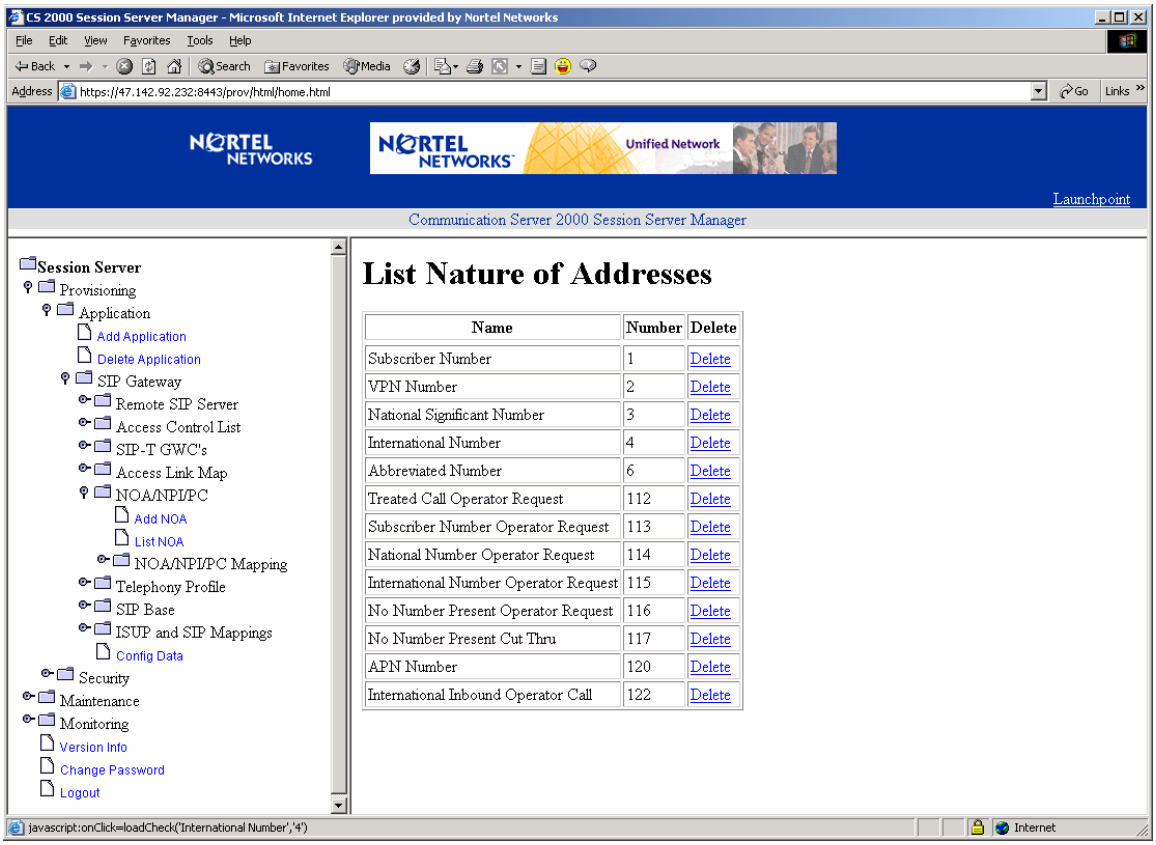

Figure 2 List Nature of Addresses

Select Add NOA menu option to add new NOA. Type in a NOA Name and NOA Number in the designated input areas and then click the Add button to complete the adding of the new NOA. If the addition of the NOA is successful, the new NOA entry will be displayed in the list of NOA's.

NOTE: Valid NOA numbers range from 1 to 150 inclusive.

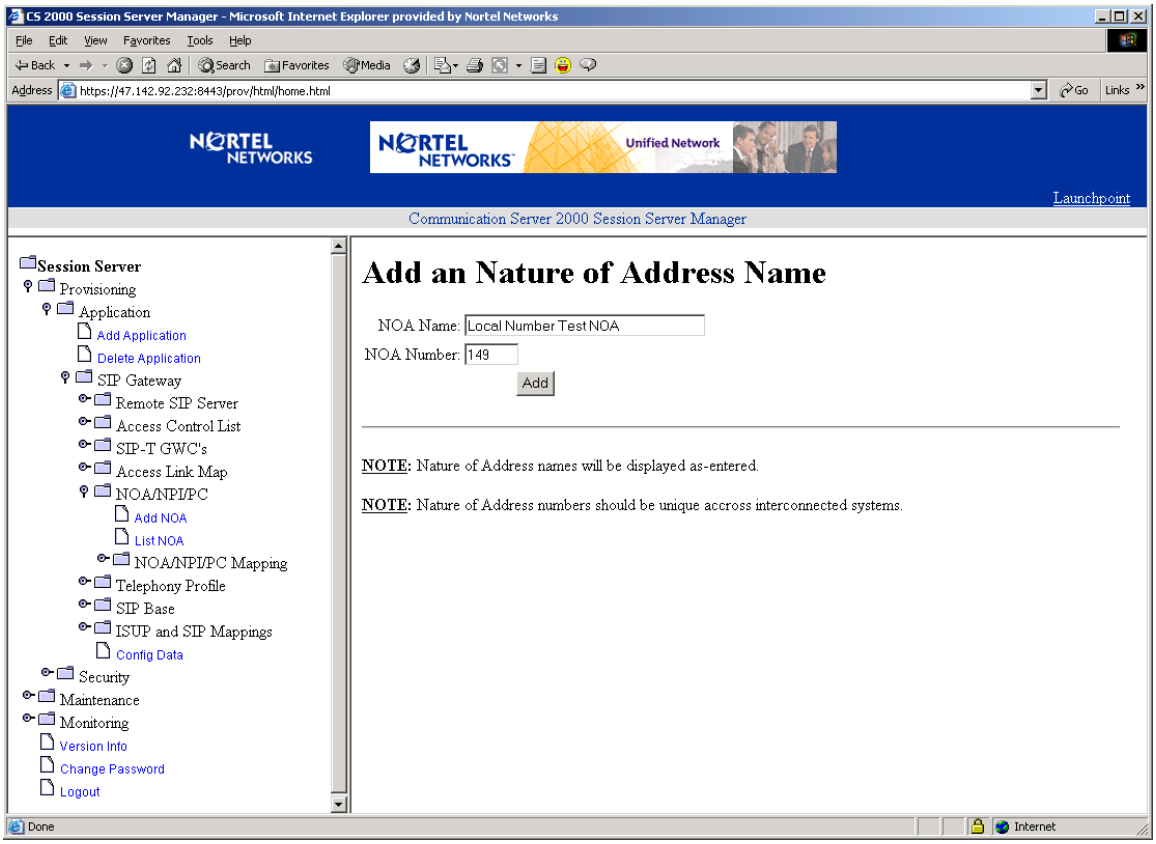

Figure 3 Add a Nature of Address Name

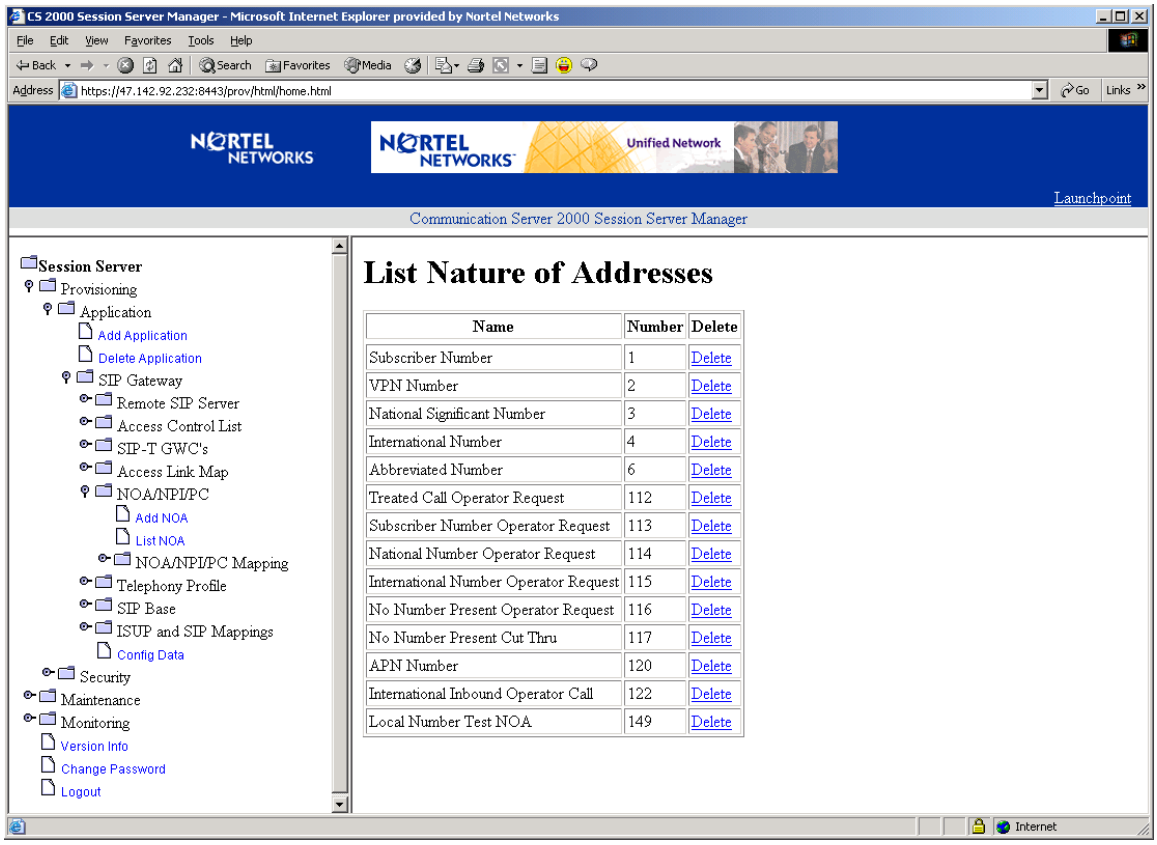

Figure 4 View of List NOA with New Entry

To delete a NOA entry, click Delete for the NOA entry to be removed and select OK in the validation pop-up window.

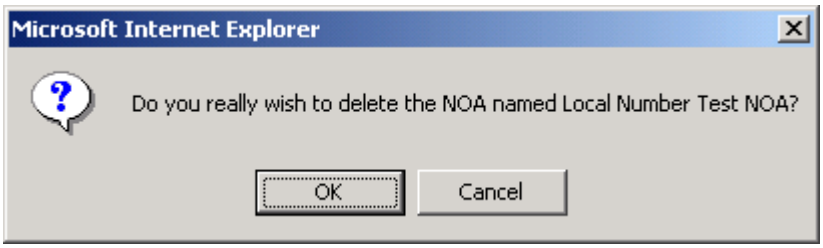

Figure 5 Delete NOA Validation Pop-up Window

The selected NOA entry is removed from the list of NOA's.

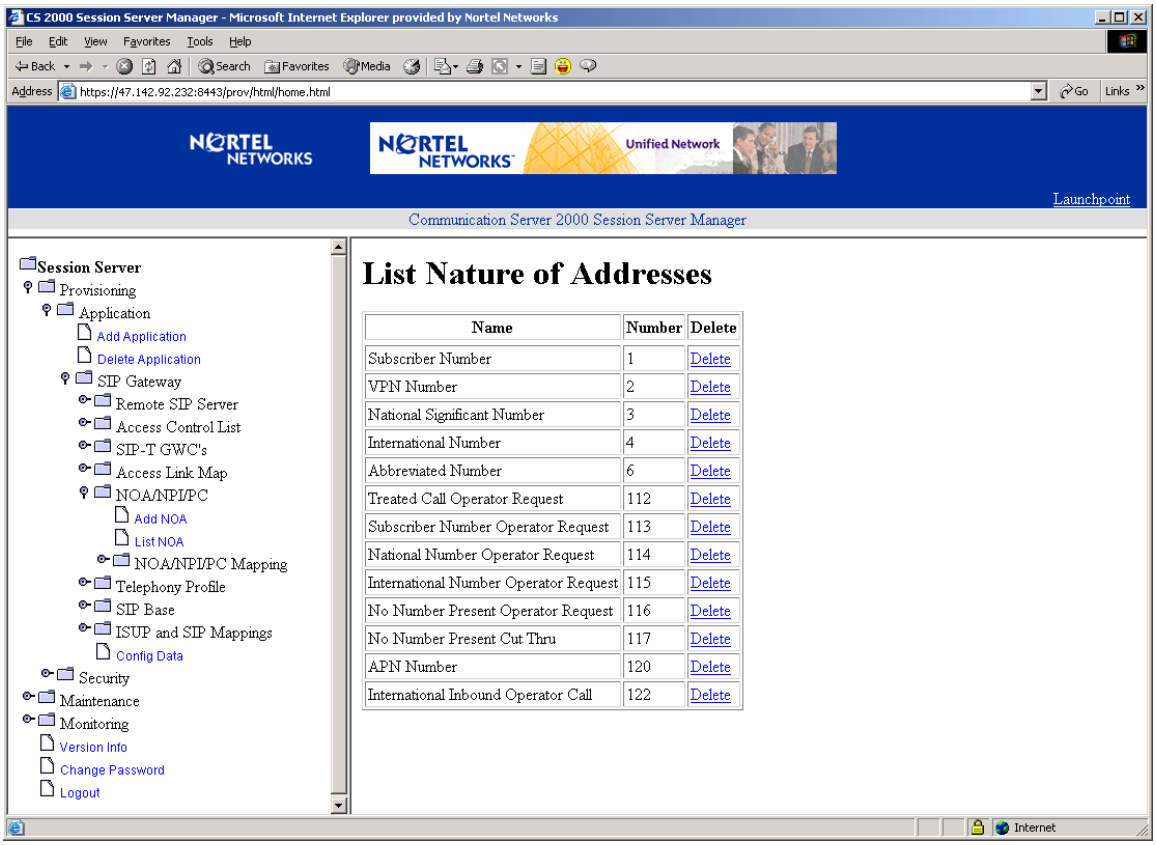

Figure 6 View of List NOA after Deletion of Entry

81.2.2.3 Addition, Deletion and Listing of Phone Context Mappings

Select the NOA/NPI/PC Mapping menu option to display Add Mapping, Delete Mapping and List Mappings menu options.

Select Add Mapping menu option to add a new NOA/NPI to Phone-Context mapping. Type in the New Mapping Name and select a Base Mapping Name from the pull down menu from the designed input areas and then click the Add button to complete the adding of the new mapping.

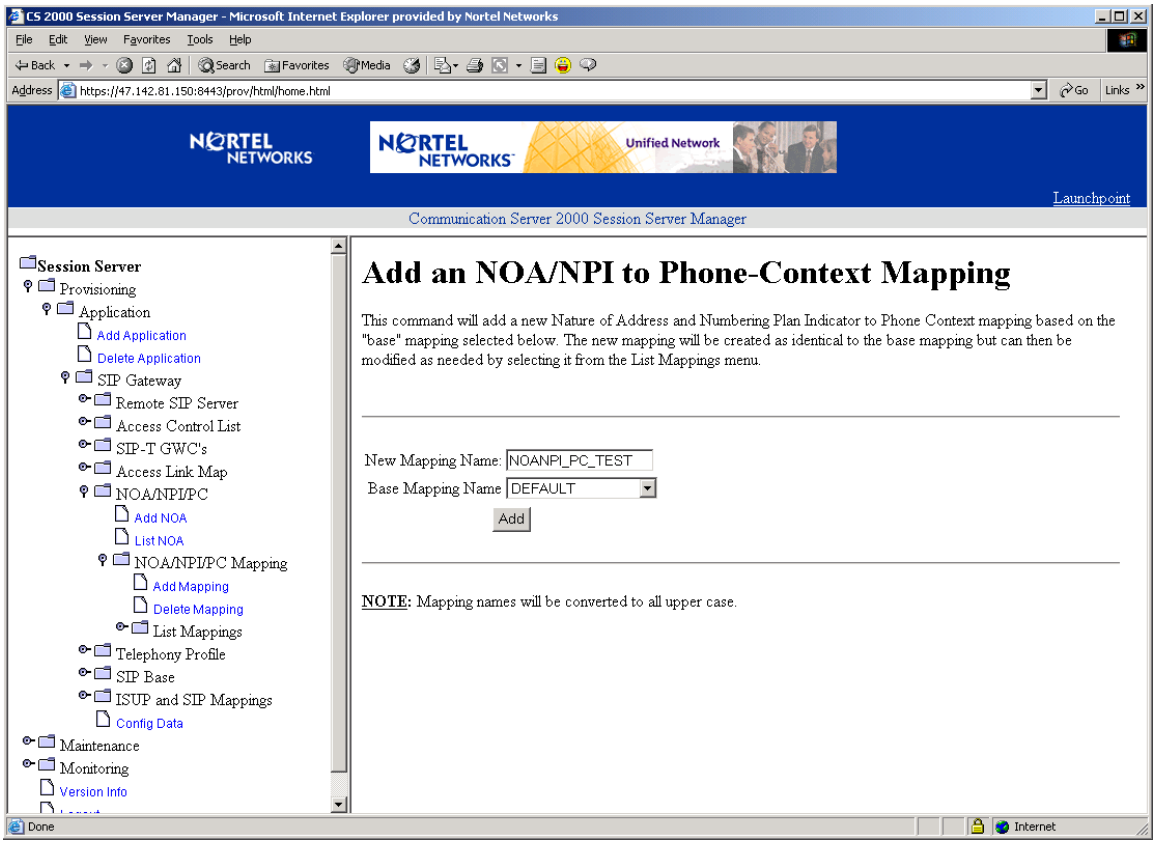

Figure 7 Add a NOA/NPI to Phone-Context Mapping

Click the Add button to add tuples to this new mapping.

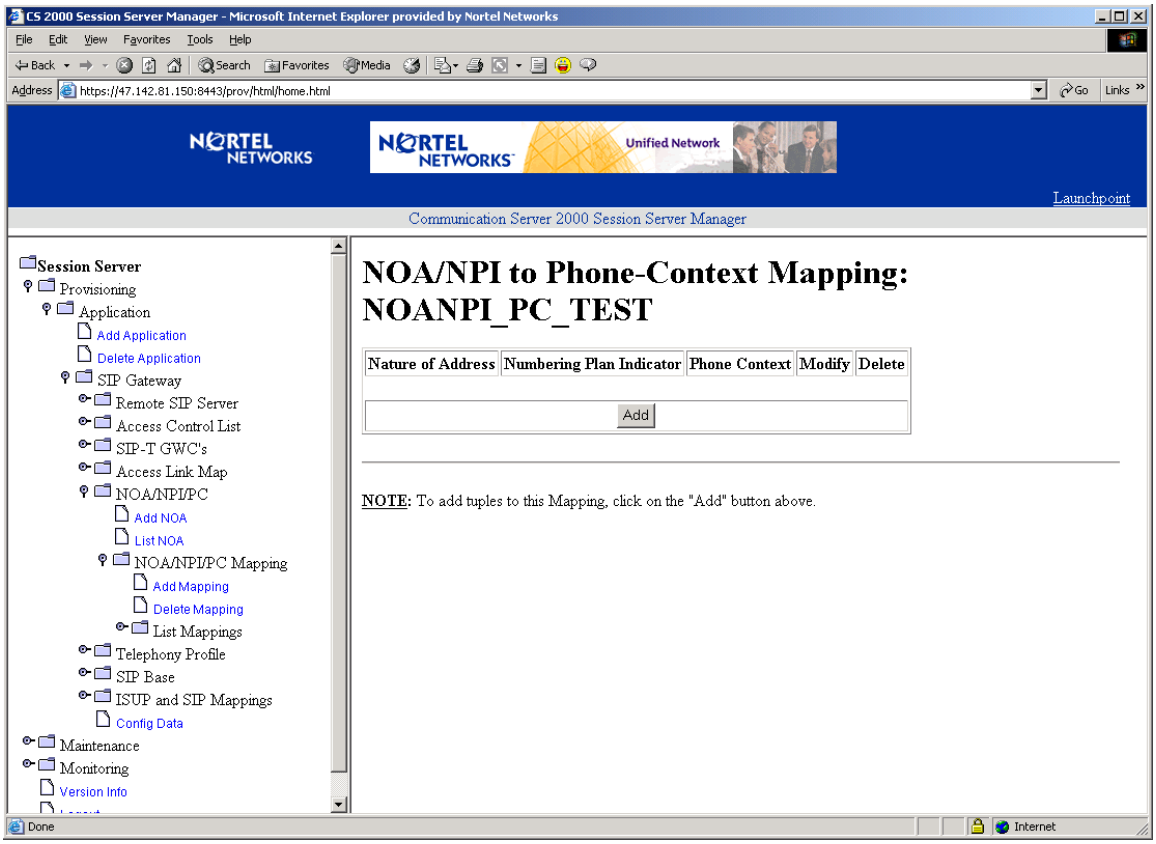

Figure 8 New Mapping NOANPI_PC_TEST View

Select Nature of Address and Numbering Plan Indicator from the pull down menus and type in the Phone Context name for this new tuple entry at the designated input areas. Click the Add button to add the new tuple.

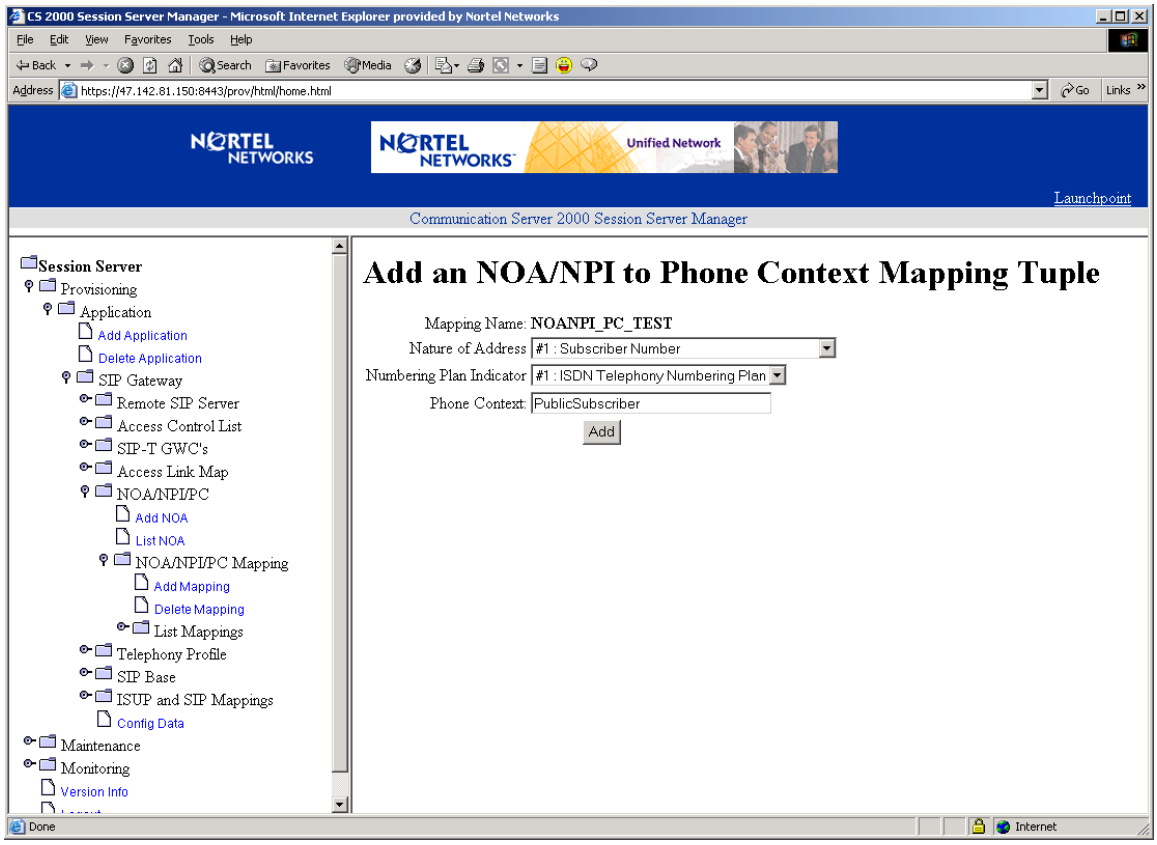

Figure 9 Add New Tuple to Mapping

If invalid selection is entered, a validation pop-up window will appear. Click OK to continue entering tuples for the mapping.

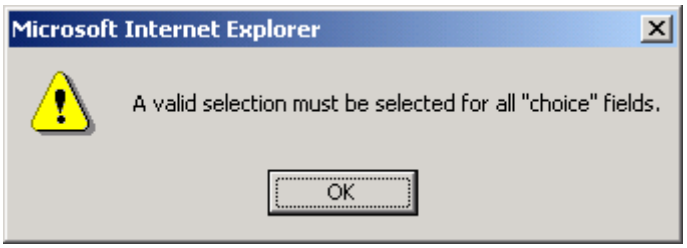

Figure 10 Invalid Selection Validation Pop-up Window

After each successful tuple addition for the mapping, the current list of tuples will be displayed.

To modify a tuple from the mapping, select Modify for the tuple.

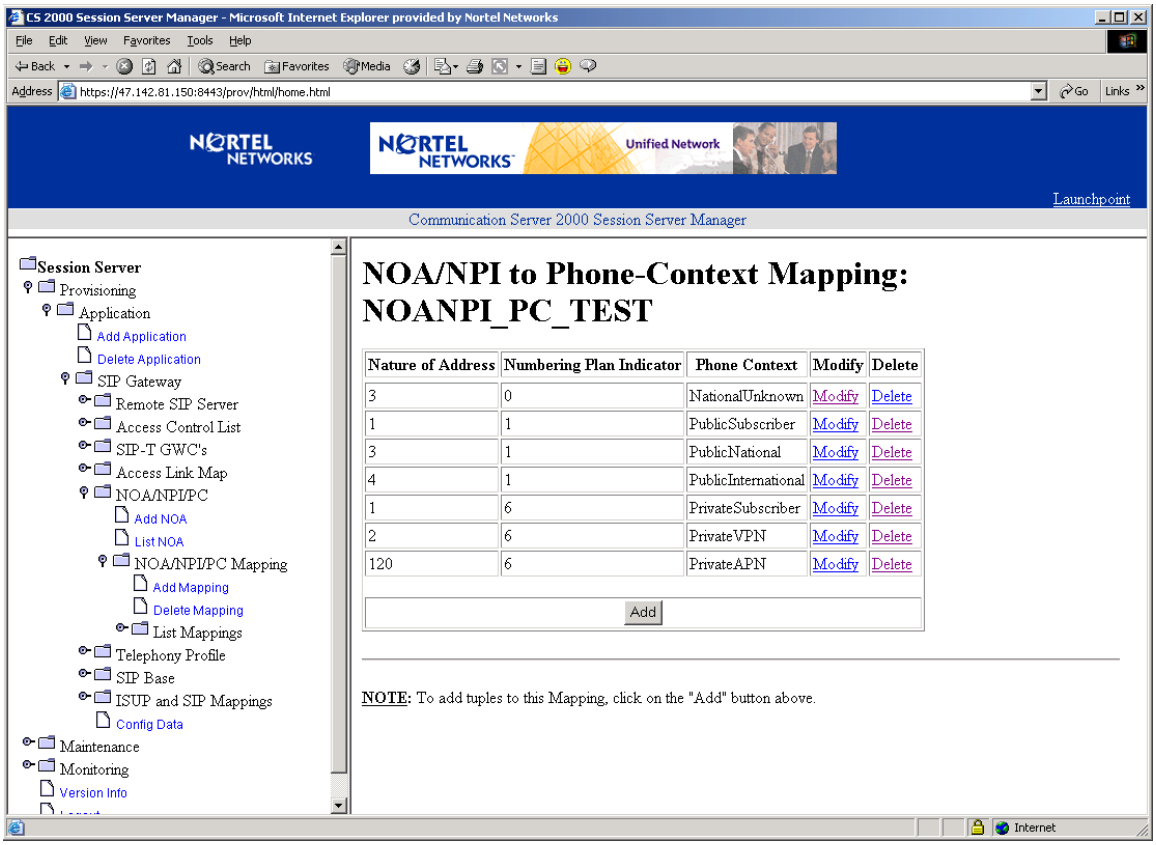

Figure 11 Tuple Listing for NOANPI_PC_TEST

The only tuple entity that can be modified is the Phone Context field.

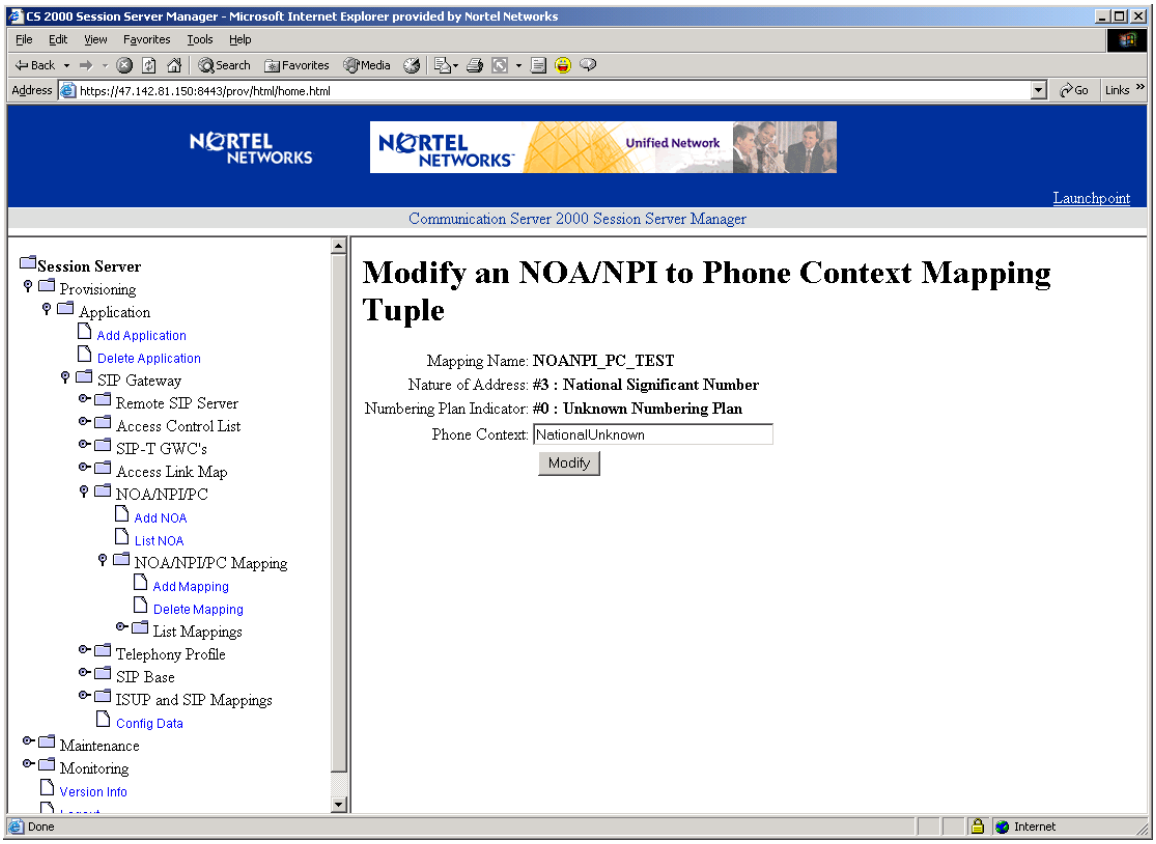

Figure 12 Modify a NOA/NPI to PC Mapping Tuple

Change the Phone Context field to the desired context then click the Modify button.

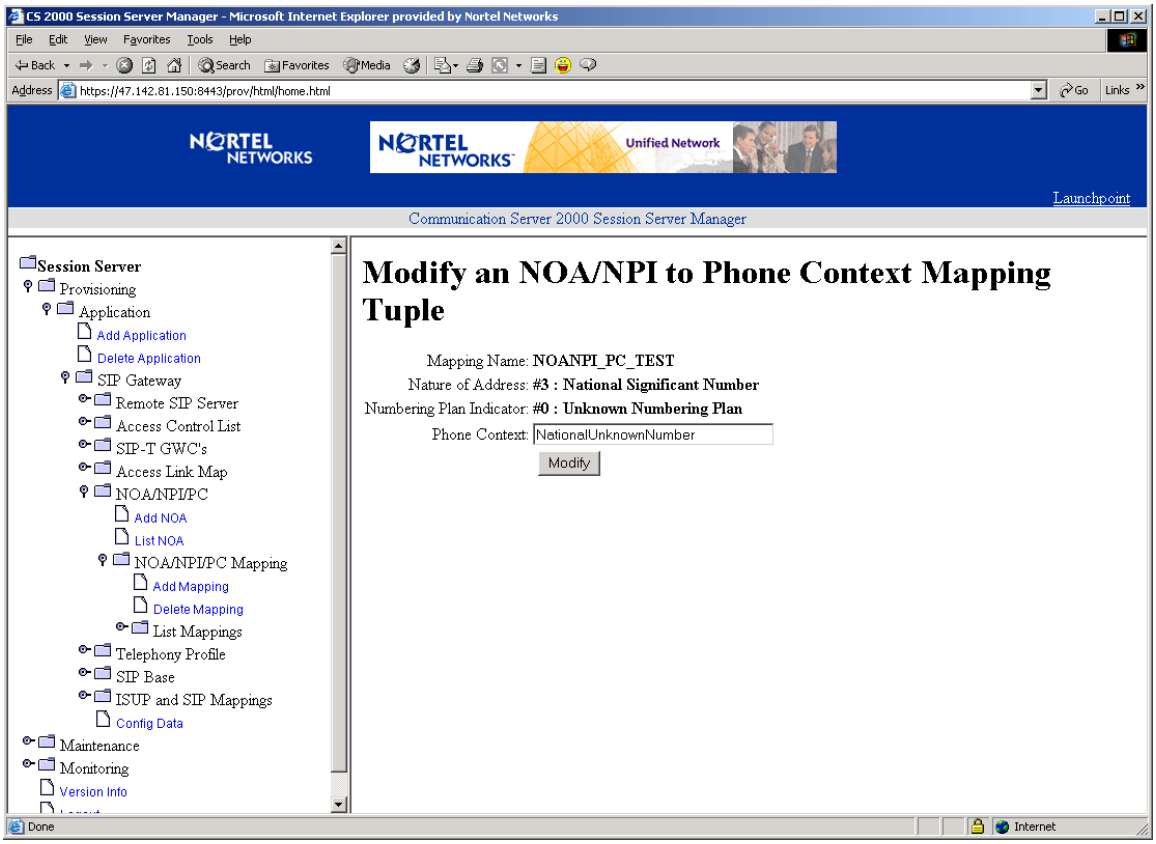

Figure 13 Modify Phone Context NationalUnknown

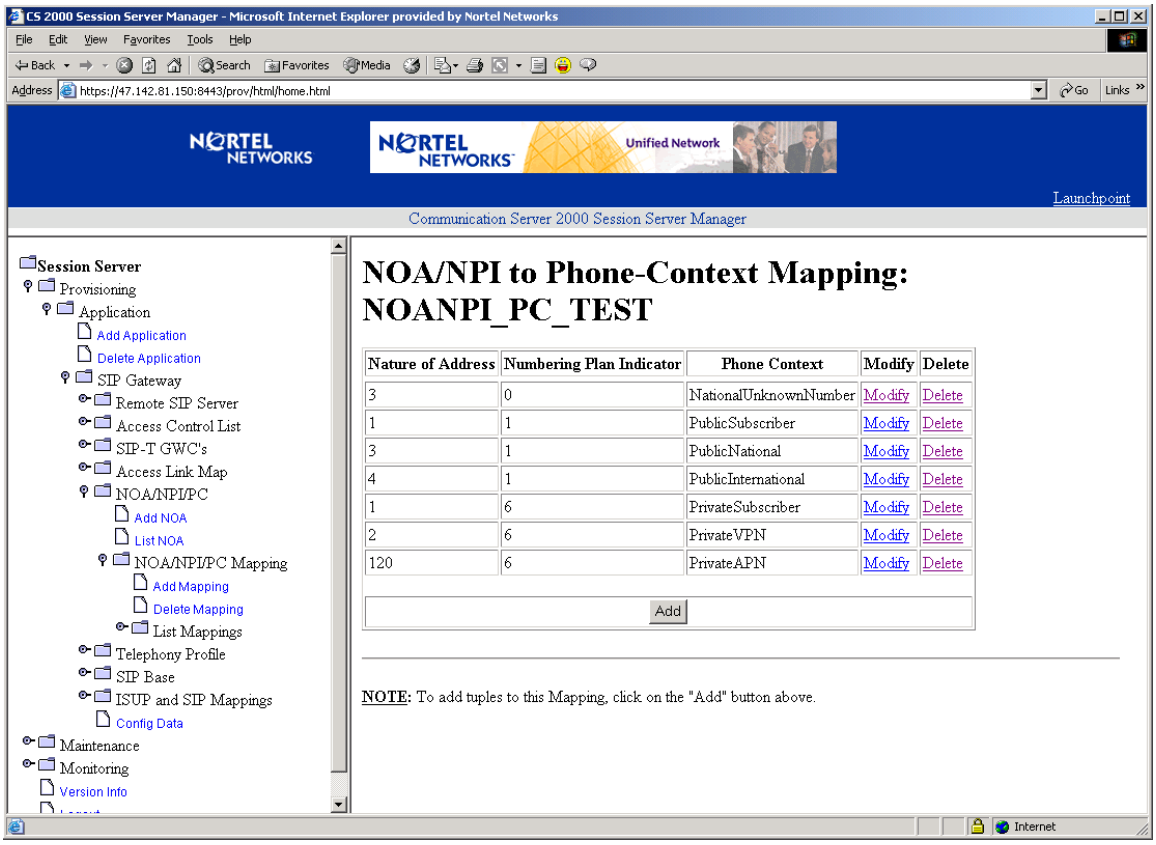

Figure 14 New Mapping Listing with Modified NationalUnknownNumber Tuple

To delete a tuple entry, click Delete for the tuple entry to be removed and select OK in the validation pop-up window.

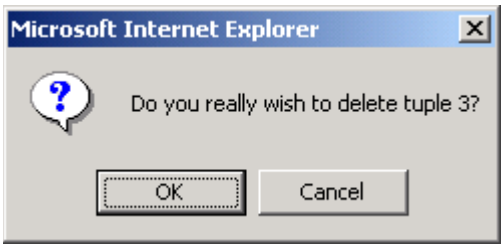

Figure 15 Delete Tuple Validation Pop-up Window

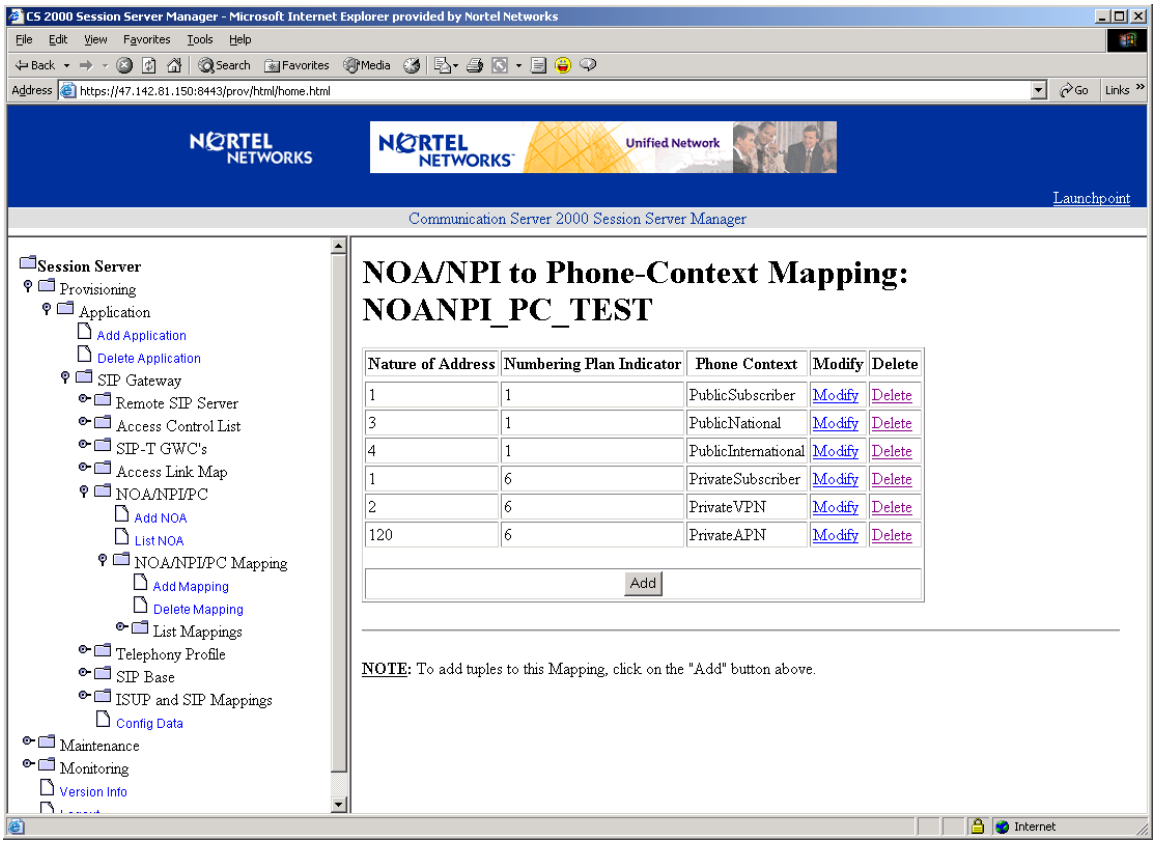

Figure 16 New Mapping Listing with NationalUnknownNumber Tuple Deleted

To view the list of phone-context mappings, select the List Mappings menu option.

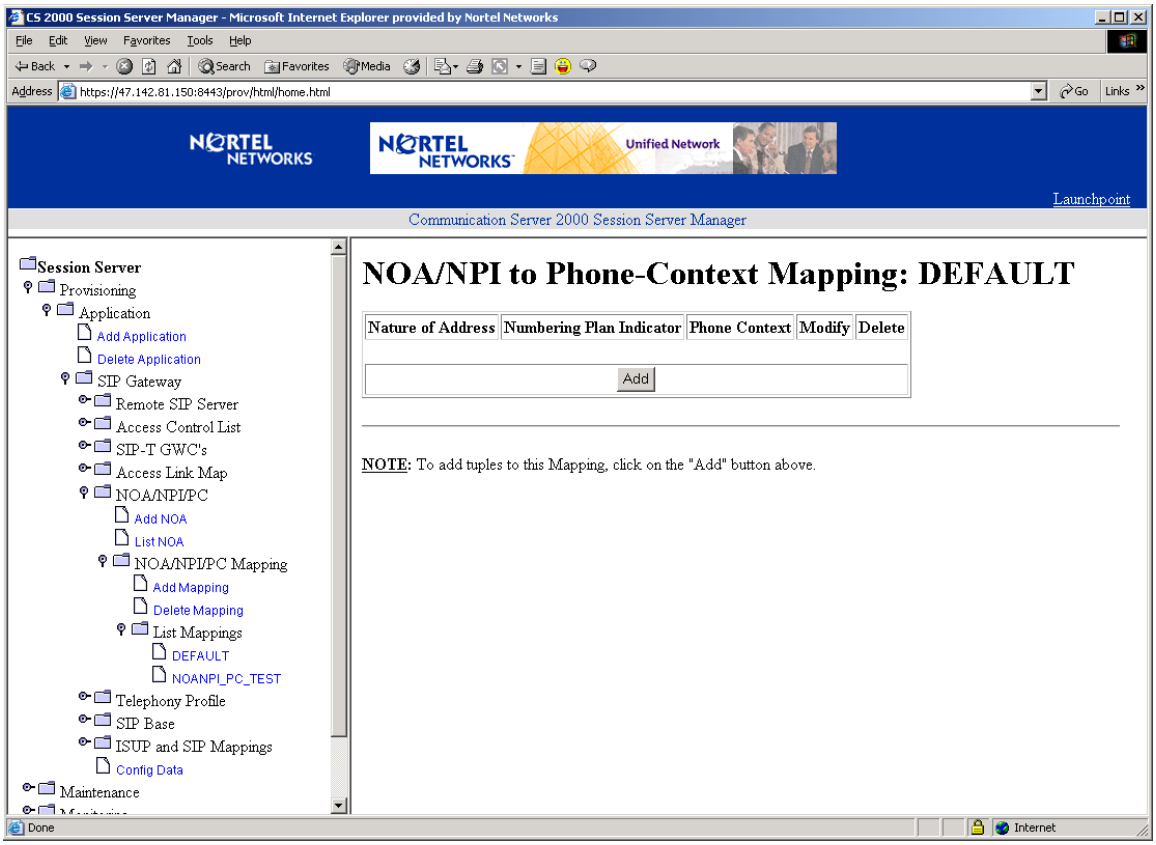

Figure 17 View of Phone-Context Mapping for DEFAULT

To view the tuples of a particular mapping, click on the mapping name under the List Mappings heading from the menu option section.

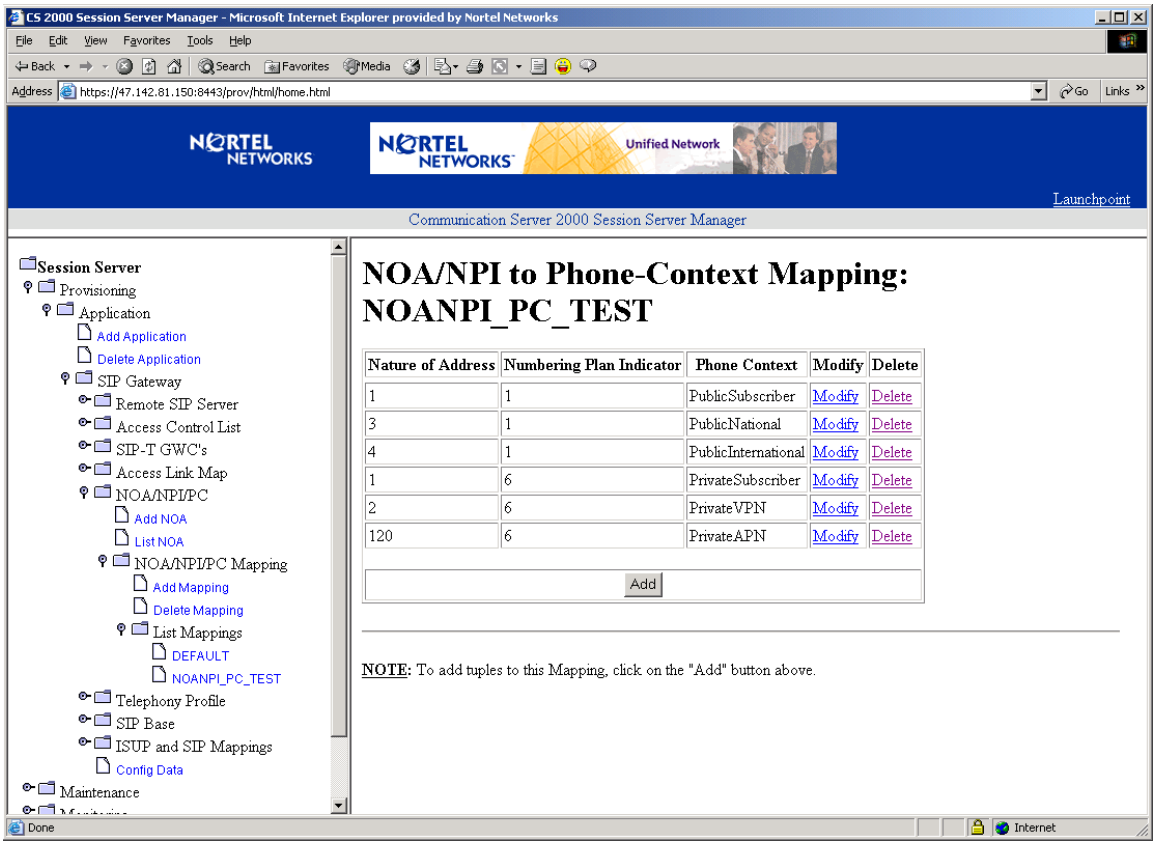

Figure 18 View of Phone-Context Mapping for NOANPI_PC_TEST

To access the section to delete a NOA/NPI to PC mapping, select the Delete Mapping menu option.

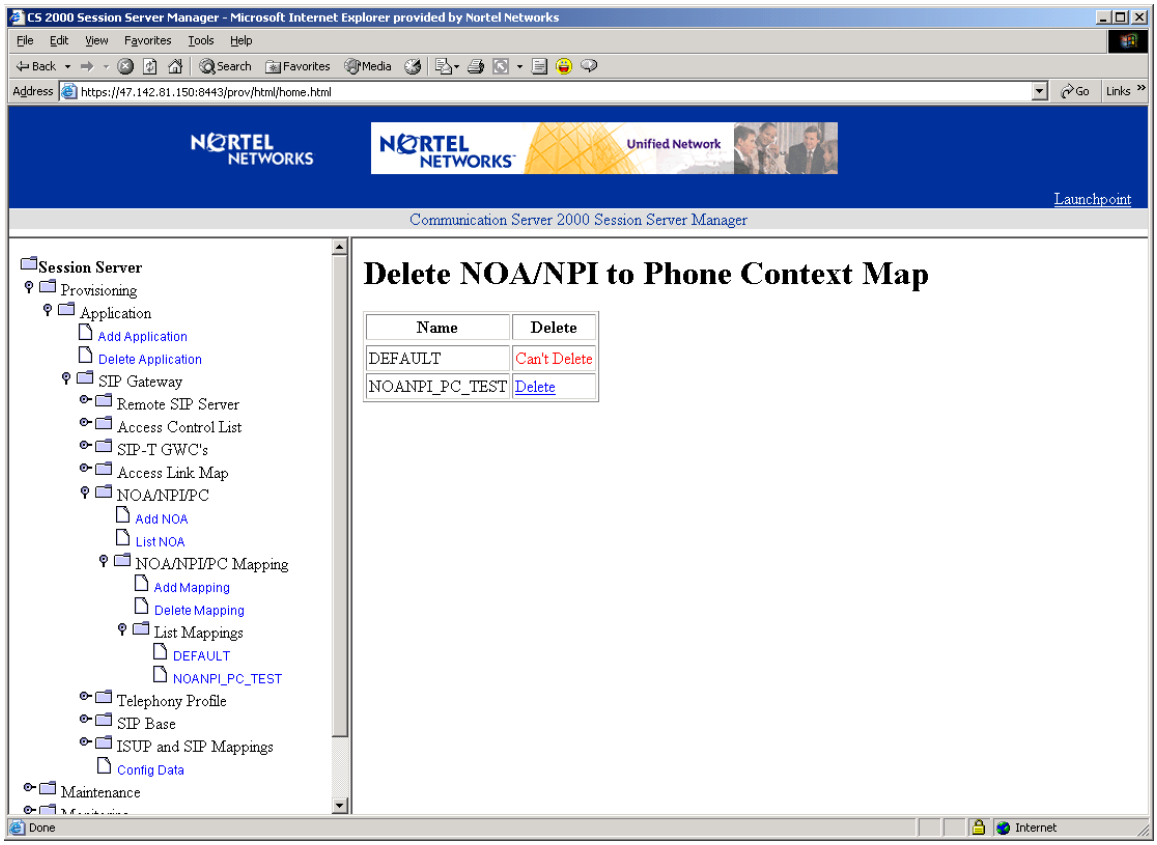

Figure 19 Delete NOA/NPI to Phone Context Map

To delete a phone context map, click Delete for the map entry to be removed and select OK in the validation pop-up window.

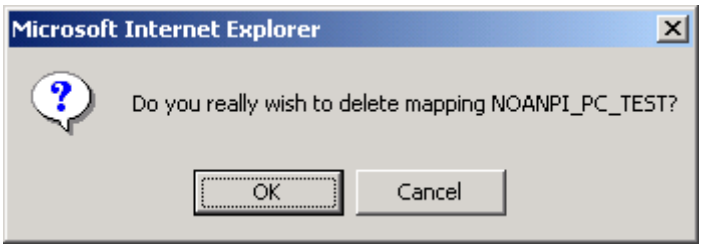

Figure 20 Delete Mapping Validation Pop-up Window

The phone context map has been removed.

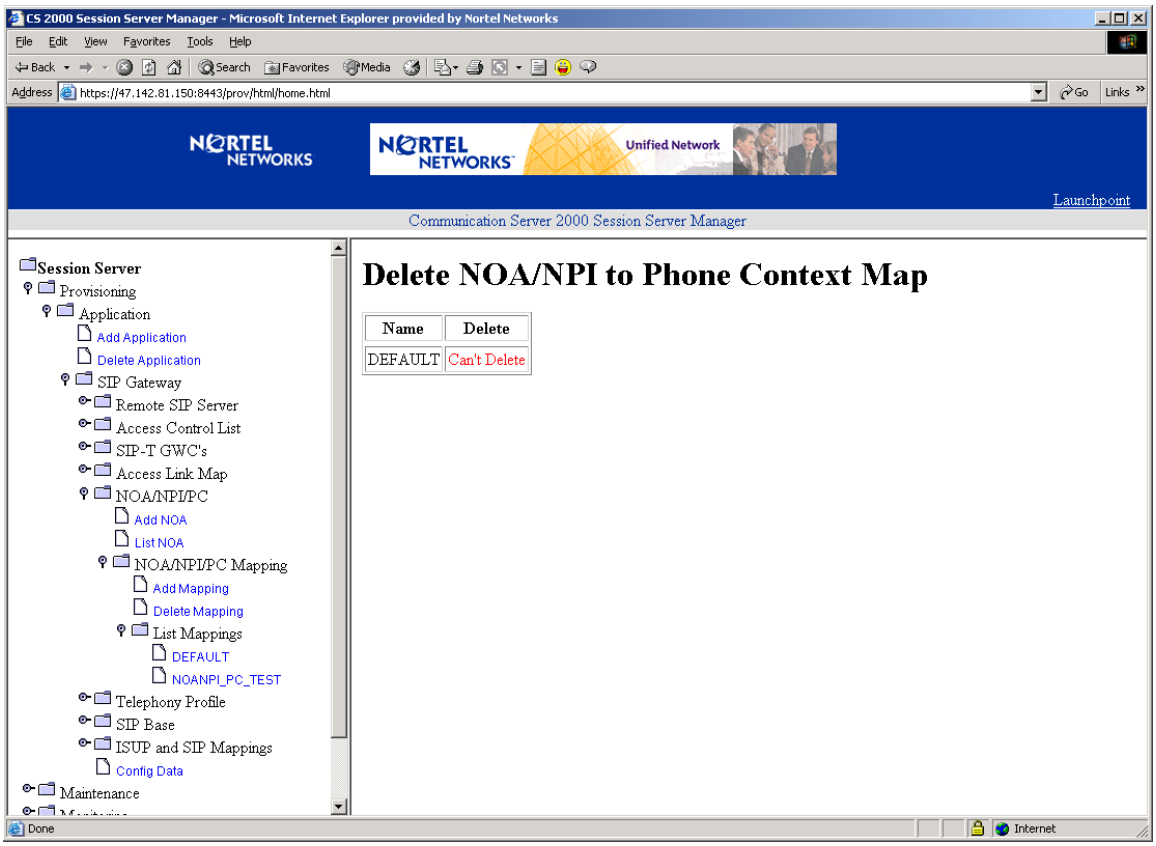

Figure 21 Delete NOA/NPI to Phone Context Map without NOANPI_PC_TEST Map

To refresh the map entries in the menu options column, select List Mappings menu option to hide mappings.

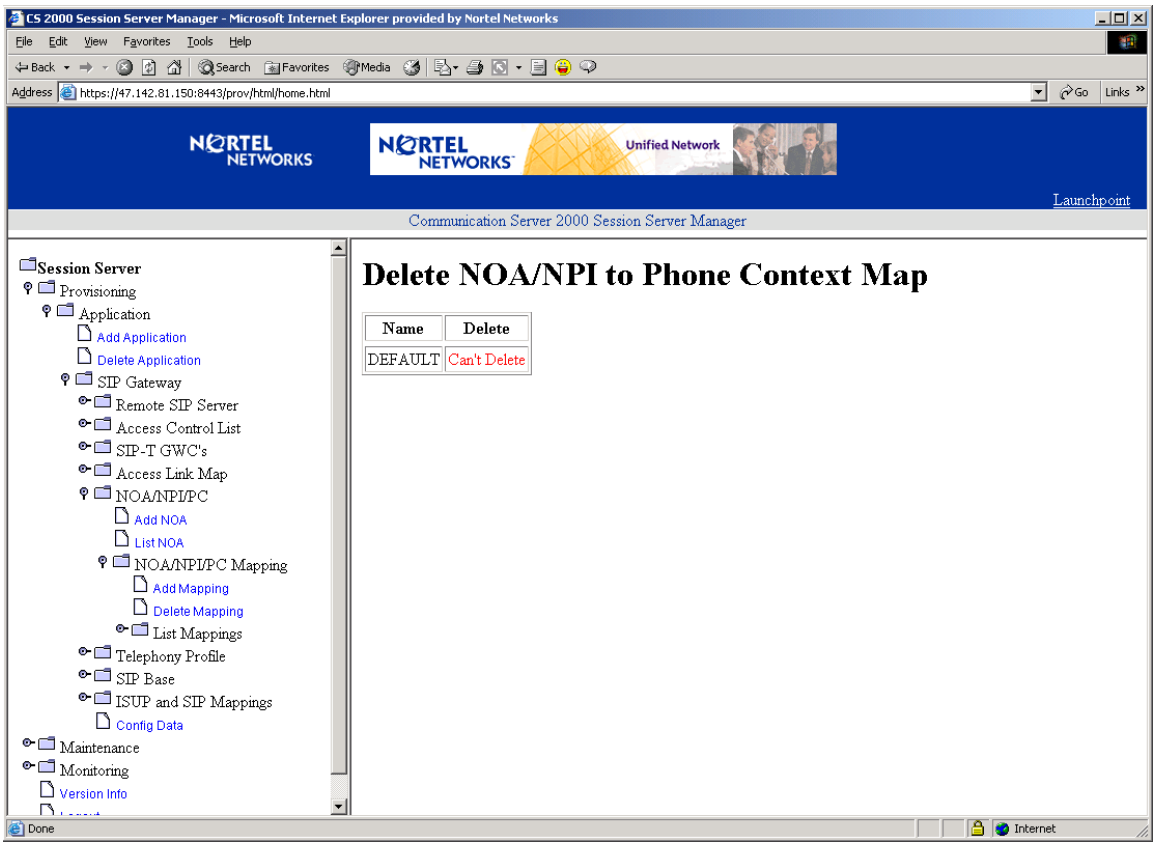

Figure 22 Hide List Mappings

To redisplay the new mappings, select List Mappings again.

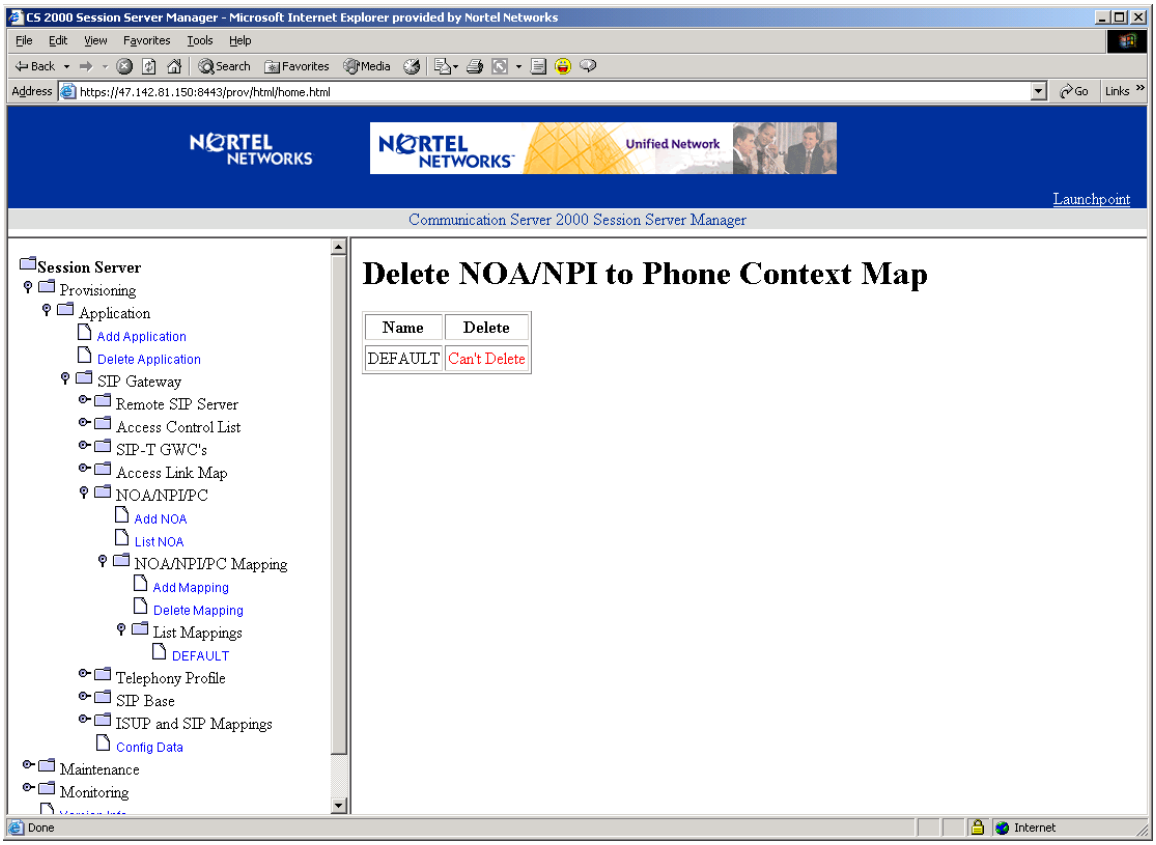

Figure 23 Display List Mappings

81.2.2.4 OOB DTMF Payload section access

Once logged in and accessed the Succession Communication Server 2000 Session Server Manager link, select Provisioning -> Application -> SIP Gateway to display the Remote SIP Server section menu option.

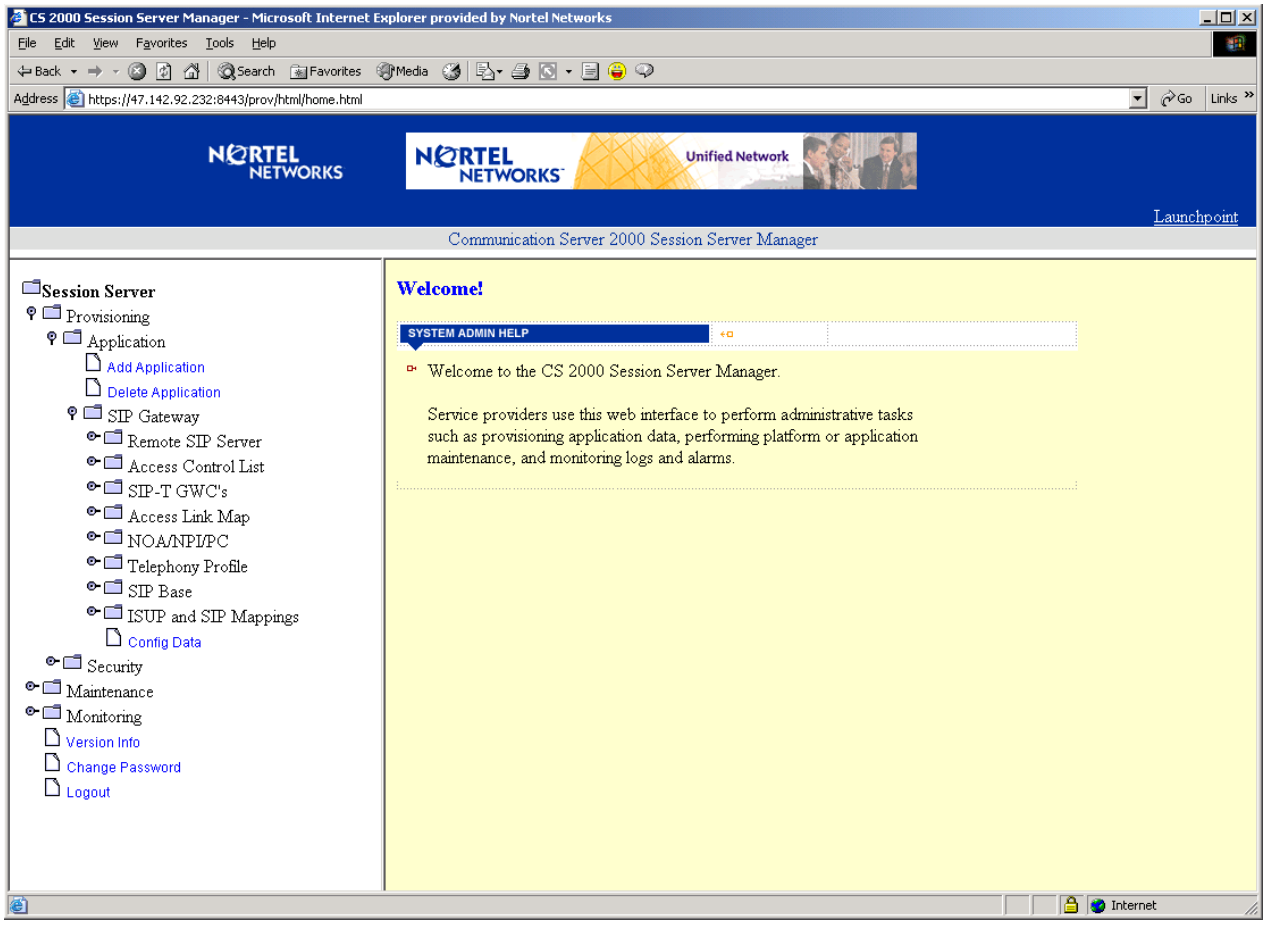

Figure 24 Remote SIP Server section access

Select Remote SIP Server menu option to display the Add Server and List Servers menu options.

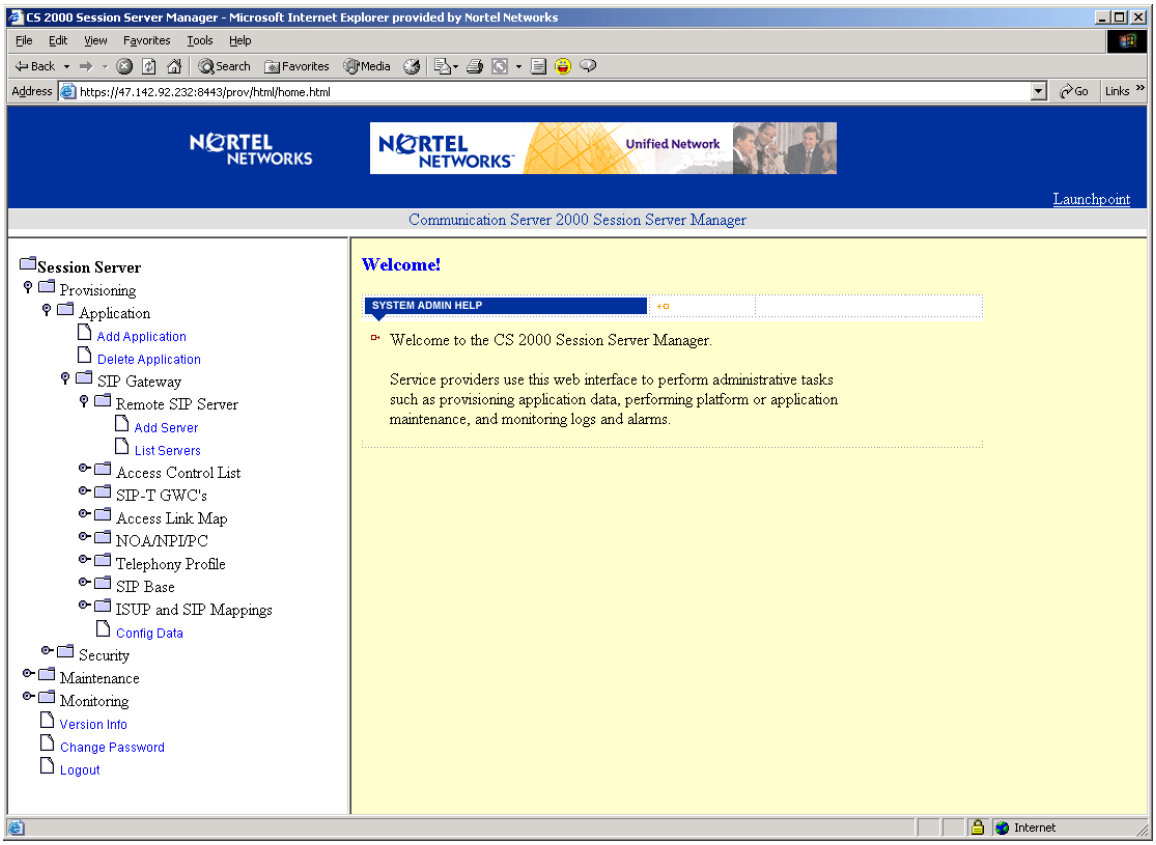

Figure 25 Remote SIP Server

Select List Servers menu option to view the current list of SIP servers.

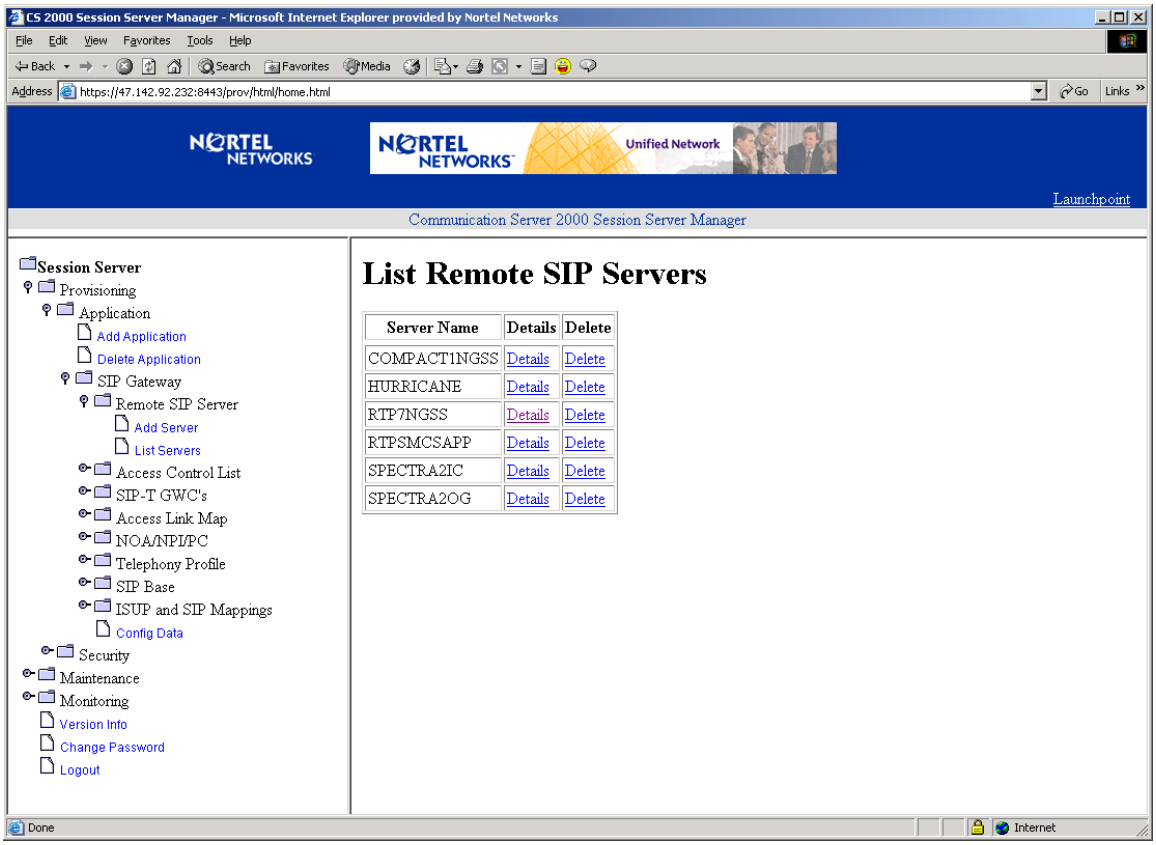

Figure 26 List Remote SIP Servers

To view the details of a particular SIP server, click Details of the Server Name to be viewed.

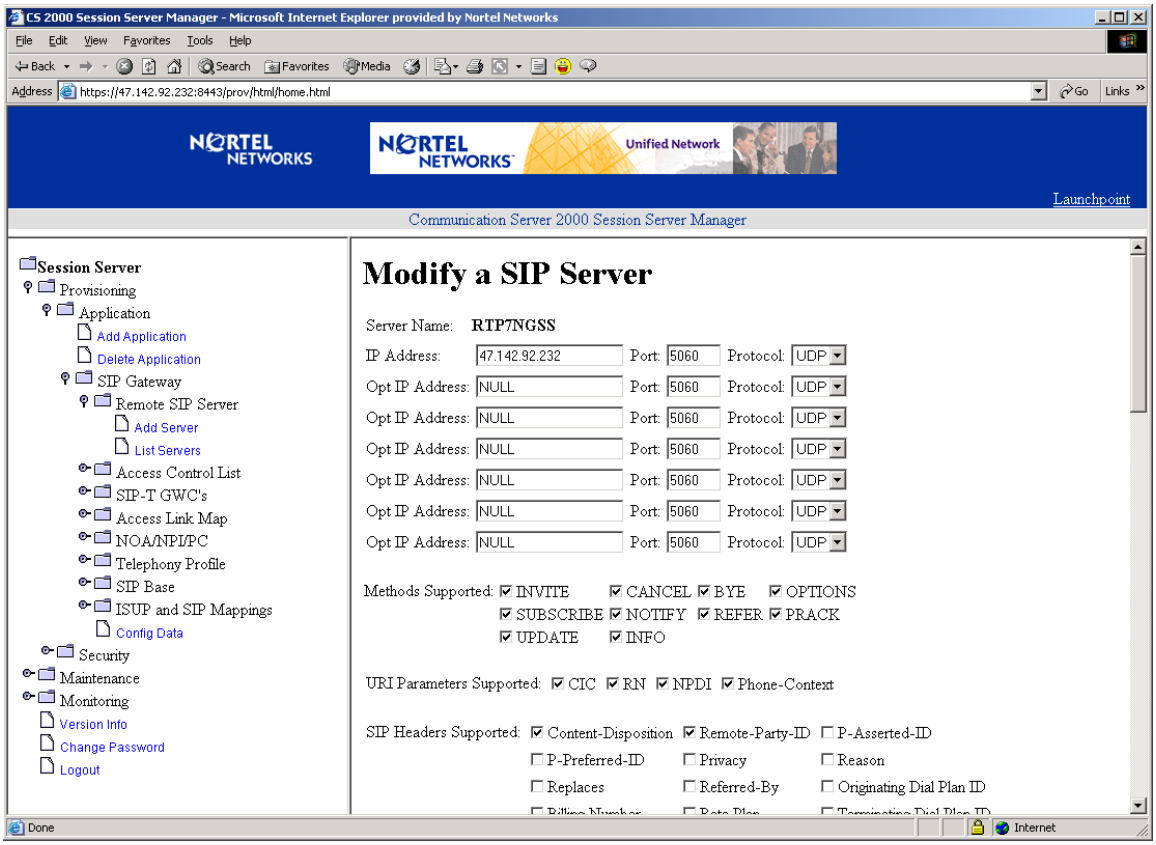

Figure 27 Modify a SIP Server

Scroll down to the Out of Band DTMF Payload option. Select application/ vnd.nortelnetworks.digits from the pull down menu for the designated input area.

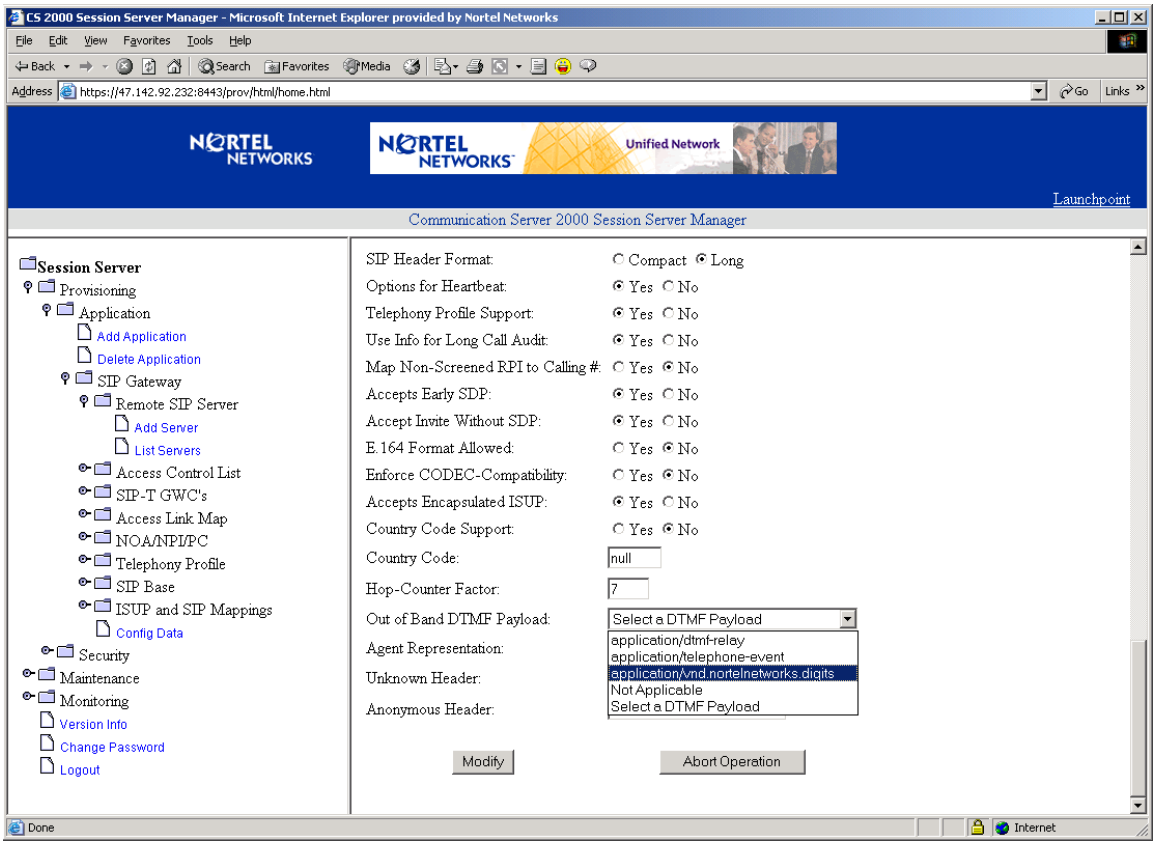

Figure 28 Out of Band DTMF Payload

To discontinue the change, click on the Abort Operation button and select OK in the abort the modification pop-up window.

Figure 29 Abort Modification Validation Pop-up Window

To accept change, click the Modify button and click OK in the modify validation pop-up window.

Figure 30 Modify SIP Server Validation Pop-up Window

To view the SIP server change, select Details of the SIP server that was changed.

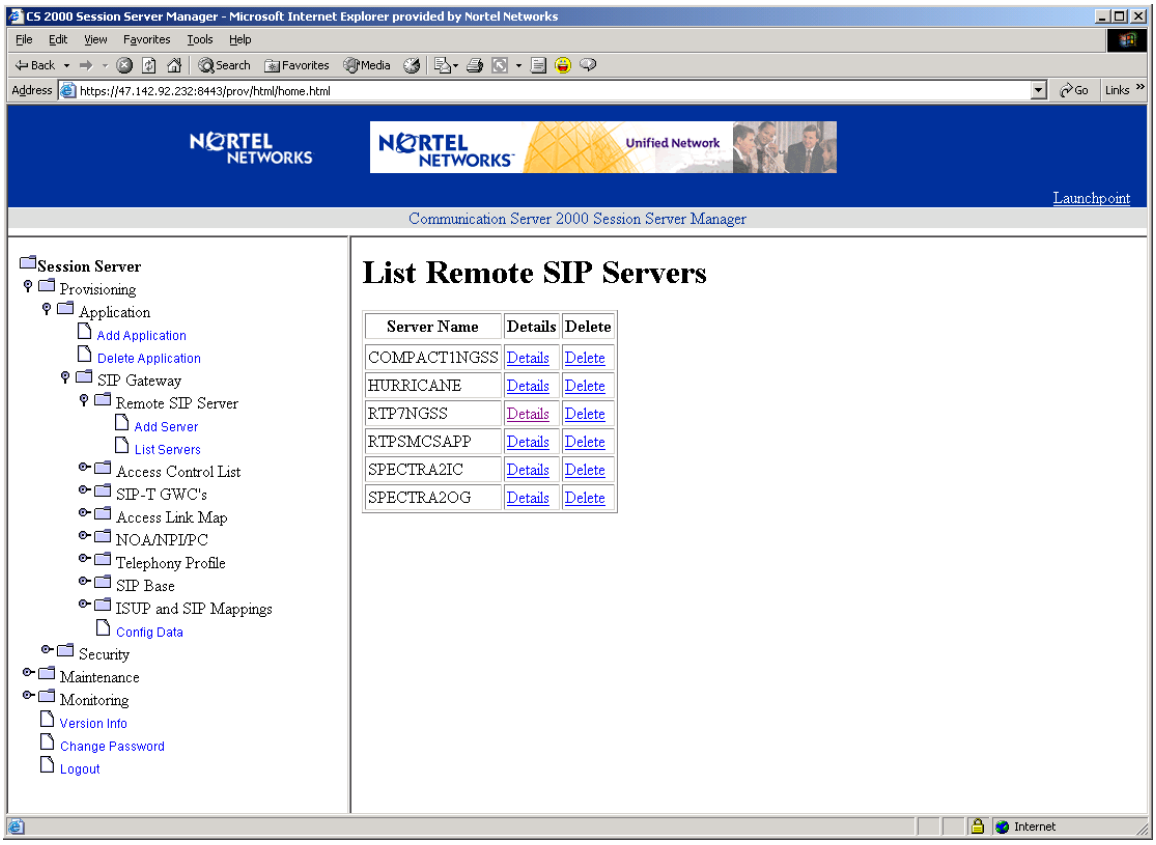

Figure 31 RTP7NGSS after Server Modification

81.2.3 Support for SIP INFO Method

Using SIP protocol, applications can establish and terminate multimedia sessions. Telephony applications that require mid session signalling, such as voice mail and meet-me conference, can accomplish that task by using one of the following ways:

RFC2833 - This standard is for defining the mechanism to encode DTMF tones within the Gate Ways (GW) and has already been implemented by most GWs.

Use of SIP INFO Message: This method is used to collect and transport DTMF digits. This activity will implements the use of SIP INFO method in Next Gen Session Server (NGSS).

A trunk option has been defined in NGSS GUI to send Out-Of-Band (OOB) DTMF tones. This option is set only if the remote server does not support RFC2833.

81.2.3.1 Outgoing CS2K Calls

When a user presses a digit on the keypad, PVG GW informs Tandem GWC about the digit. Tandem GWC sends INFORM message to the SIP GWC with digit payload. SIP GWC sends a GCP message to the Session Server (NGSS) with the tone information. NGSS checks the trunk options and if the option is **vnd.nortelnetworks.digits** OOB signalling will be used. In this case the INFO message with the DTMF payload will be sent to the remote server.

Following is a sample of the INFO message sent to the remote server:

```
INFO sip:123456@47.104.11.31:5060 SIP/2.0
v: SIP/2.0/UDP 47.104.11.207:5060
t: <sip:123456;phone-
context=myContext@enterprise.com;user=phone>;tag=345496207
f: UserA <sip:userA@enterprise.com>;tag=1652960069
m: <userA@47.104.11.205:5060;transport=udp>
i: 351f114f_f46db6dfe9@zngcs01
CSeq: 79007 INFO
c: application/vnd.nortelnetworks.digits
l: 35
p=Digit-Collection
y=Digits
d=1
```

Note that for outgoing CS2K calls, CS2K will send the INFO with digits to MCS only in a 323-SIP_MCS inter-working when the originating 323 does not support RFC2833.

81.2.3.2 Incoming CS2K Calls

For incoming CS2K calls, once NGSS receives an INFO message, the trunk option is checked and if **vnd.nortelnetworks.digits** is present, the new INFO template is used to parse the message and extract the digits.

81.2.4 Support for Public and Private Name/Number Display

In MCS09/SN09, enhancements are being made to extended the concepts of Public and Private Name and Number display within Centrex customer groups across the MCS CD (Converged Desktop) services. Enhancements to MCS are made under the feature A00009905, “Private Public Name and Number Display”. Enhancements are made to display the Private Name / Number information to the called party within the same Centrex group and the Public Name/Number to the called party outside the Centrex group. CS2K changes, specifically to the NGSS, are made under this feature to support these enhancements.

Directory Numbers within a Centrex customer group can be provisioned with a Public Display Name and a Private Display Name. Centrex features allow the Private Name and Number (which might be a 5 digit number) to be

displayed on calls between parties within the same Centrex customer group. They also allow the Public Name and Number (which can be a 10 digit PSTN number) to be displayed when the parties are not in the same Centrex customer group, such as when one of the parties is a PSTN caller.

Using MBG over IT trunks allows Centrex customer groups and their related services to be extended to Directory Numbers hosted off of different DMS switches. In the following figure, if party A and party B are in the same Centrex group, the Private Name and Number can be displayed.

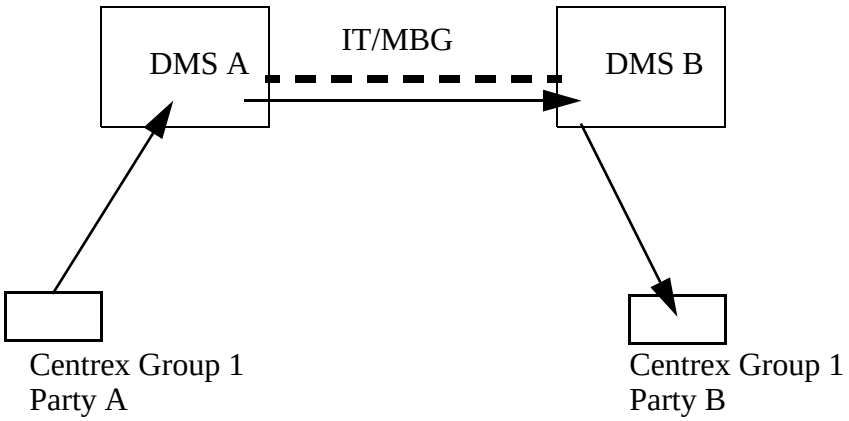

Figure 32 Extension of Centrex Groups using MBG

As in the following diagram, if one of the parties is a PSTN caller, the Public Name and Number can be displayed.

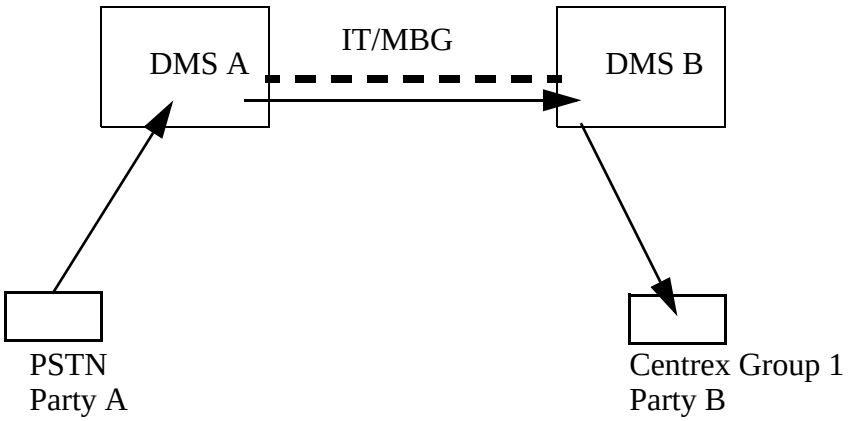

Figure 33 Call from outside the Centrex Group

The equivalent of a Centrex business group on the MCS system is a domain or sub-domain. A Private call is made within the domain or sub-domain. A Public call is one made outside the domain boundaries.

MCS CD functionality allows users to have an MCS Multimedia PC Client that can be used with a headset for VoIP telephony calls, as well as a PAD (Personal Audio Device) that can be an office telephone. The MCS PC Client has a display window that displays call status and can be used to control interactions between the Desktop telephone and the PC Client, such as controlling which phone to ring.

A basic diagram of a Converged Desktop system configuration is shown below..

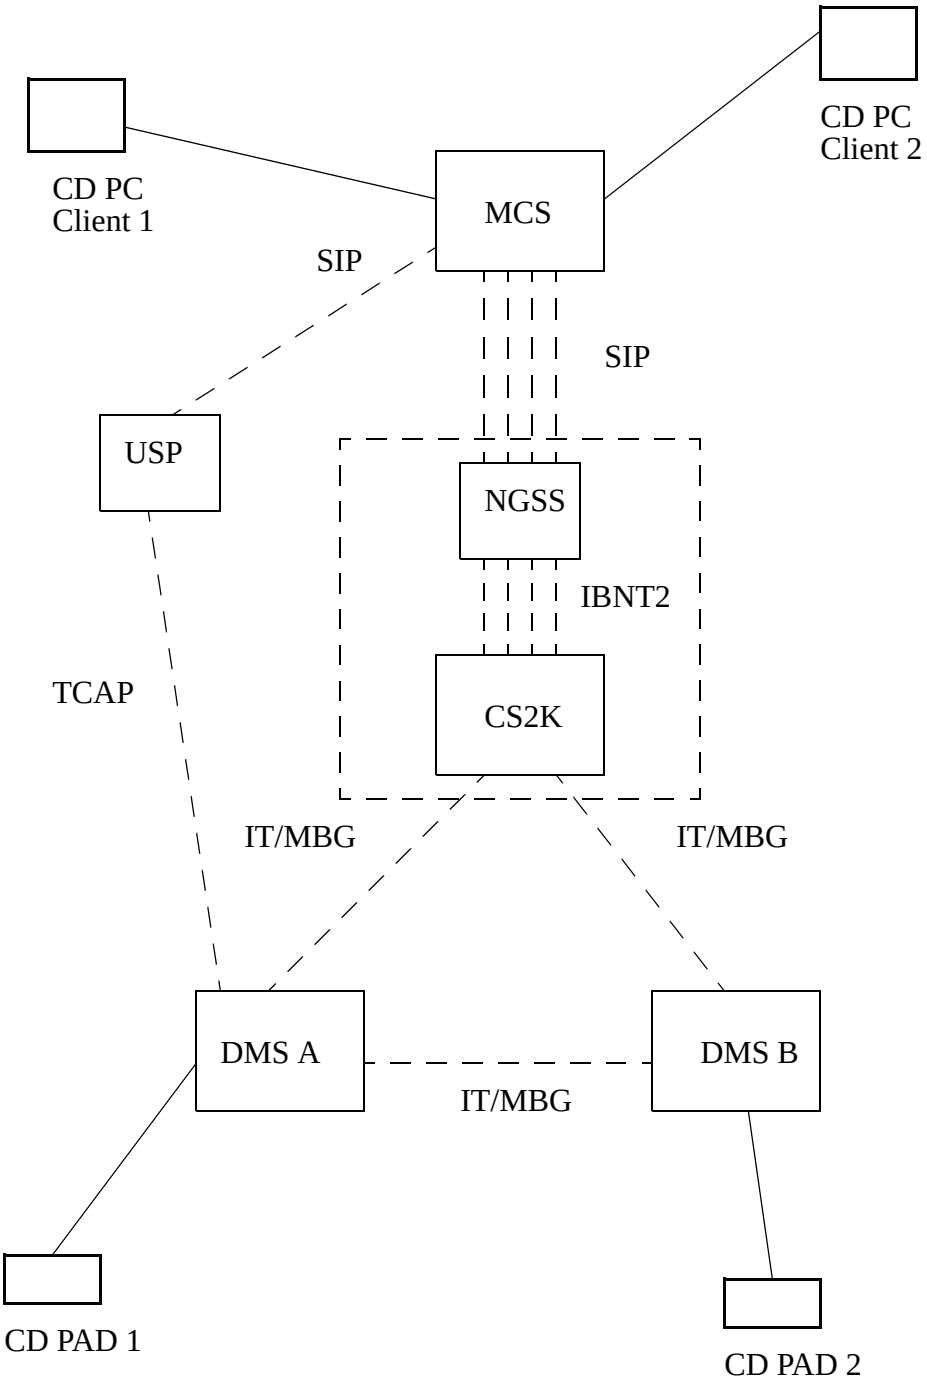

Figure 34 Converged Desktop Network Diagram

IT/MBG trunks are provisioned between DMS 100s and the CS2K to be shared among customer groups. MBG allows members of the same Centrex customer group to be known across different DMSs. IBNT2 SIP trunks are provisioned between the CS2K and the MCS, one dedicated per customer group.

The NGSS acts as the interface between the MCS and CS2K DPT trunking. The NGSS communicates using GCP protocol on the DPT trunks through a SIPT Gateway Controller. It communicates with the MCS using SIP. The IT/MBG trunks are ISUP trunks.

The USP provides an SS7 TCAP interface for the DMSs, and a SIP interface for the MCS.

CD User 1 has a CD PC Client and a CD PAD, as does CD User 2.

In the CD environment, there exists a number of complex call flows. Within these call flows, the Name and Number Displays on the CD PADS and on the CD PC Clients need to be consistent in terms of whether the Private or Public displays are used. If the two CD PADs are within the same Centrex business group, the Private Name and Number displays should be maintained.

An example of a complex call flow is given in the figure below.

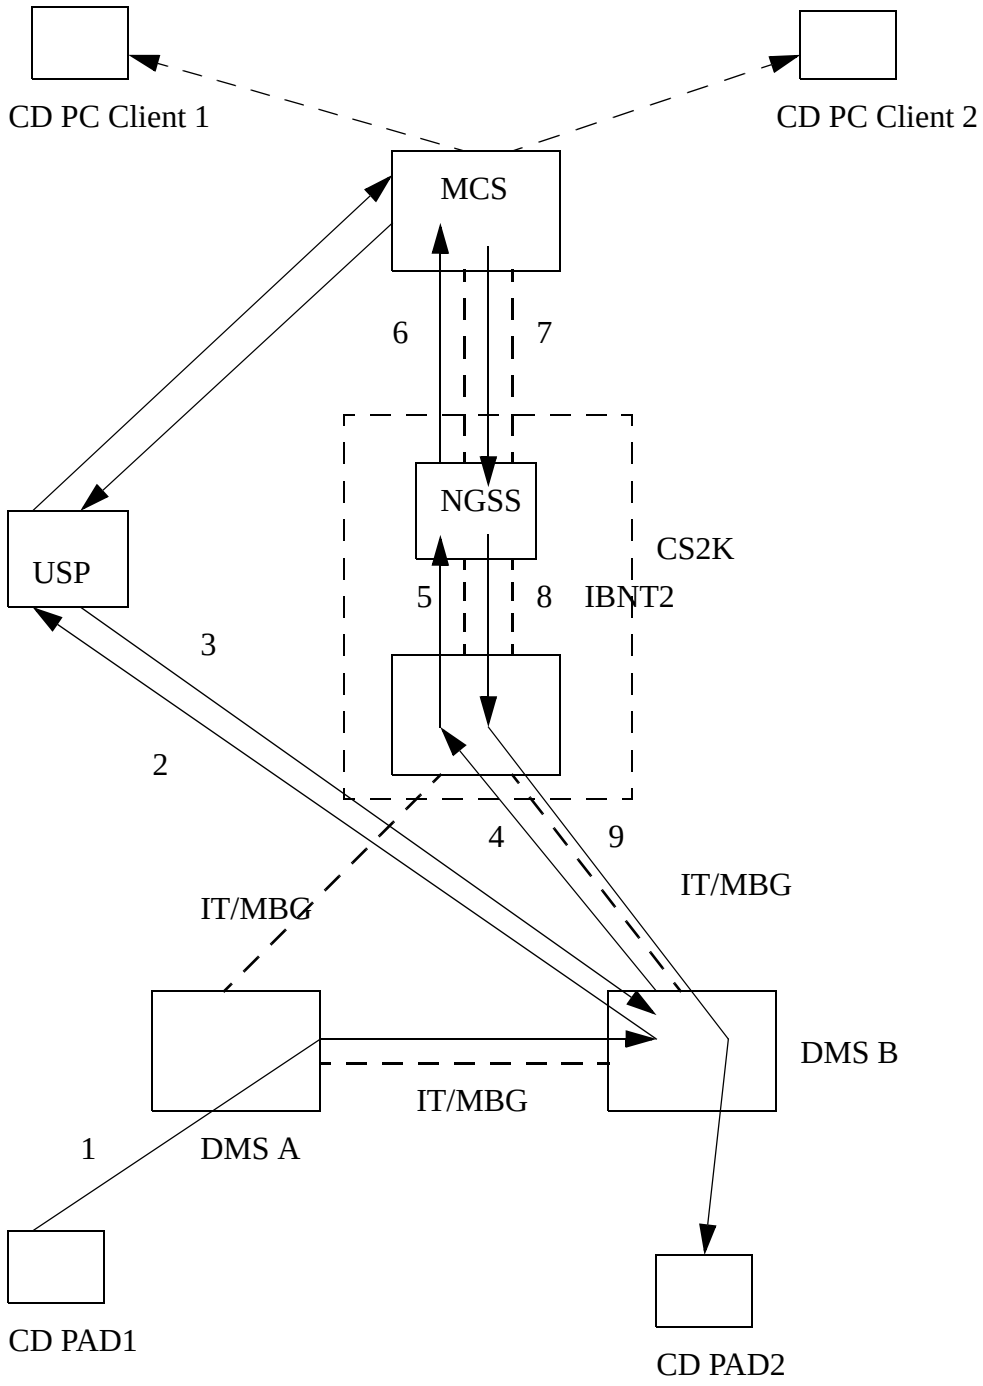

Figure 35 Converged Desktop System Call Flow

In this call, CD PAD1 and CD PAD2 are in the same Centrex group. The steps in the call flow are as follows:

In step 1, CD PAD1 calls CD PAD2. Since CD PAD2 is a converged desktop user, its Directory Number has a TAT trigger associated with it.

This causes step 2, where a TCAP query is generated to the USP, which in communicating with the MCS returns in step 3 the SDN (Converged Desktop Service Directory Number) associated with the Centrex business group of the called party. This is the SDN that the MCS has associated with the sub-domain of the called party. This tells the DMS to route the call to the SDN.

In step 4 the call is routed to the SDN for the business group over an IT/MBG trunk to the CS2K. The identity of the business group is maintained across the ISUP IT trunk by the MBG parameter. At the CS2K in step 5, the call is routed over a dedicated IBNT2 trunk for the business group. In this step, the ISUP call setup information is carried to the NGSS through the GCP protocol. The NGSS converts the call setup information to a SIP INVITE message to be sent to the MCS in step 6. The SIP INVITE message contains an X-Nortel-Profile header that associates the call with the specific business group.

The MCS performs the logic to update the status of the CD PC Client displays. In this call scenario, it is determined that CD User 2 has indicated through configuration that he wants the call to be routed to his telephone, CD PAD2.

In step 7, the MCS routes the call to the NGSS over the route associated with the business group. In step 8, the NGSS routes the call over the IBNT2 DPT trunk associated with the business group to the CS2K. In step 9, the CS2K routes the call over an IT/MBG trunk to DMS B, which, which after making another TAT trigger query to the USP terminates the call the call to CD PAD2.

Since in this scenario both CD users are in the same Centrex business group, the CD PAD2 display will use the Private Name and Numbers. The CD PC Clients displays will also be Private.

A similar call scenerio is shown below, but in this case the calling party is not in the Centrex business group.

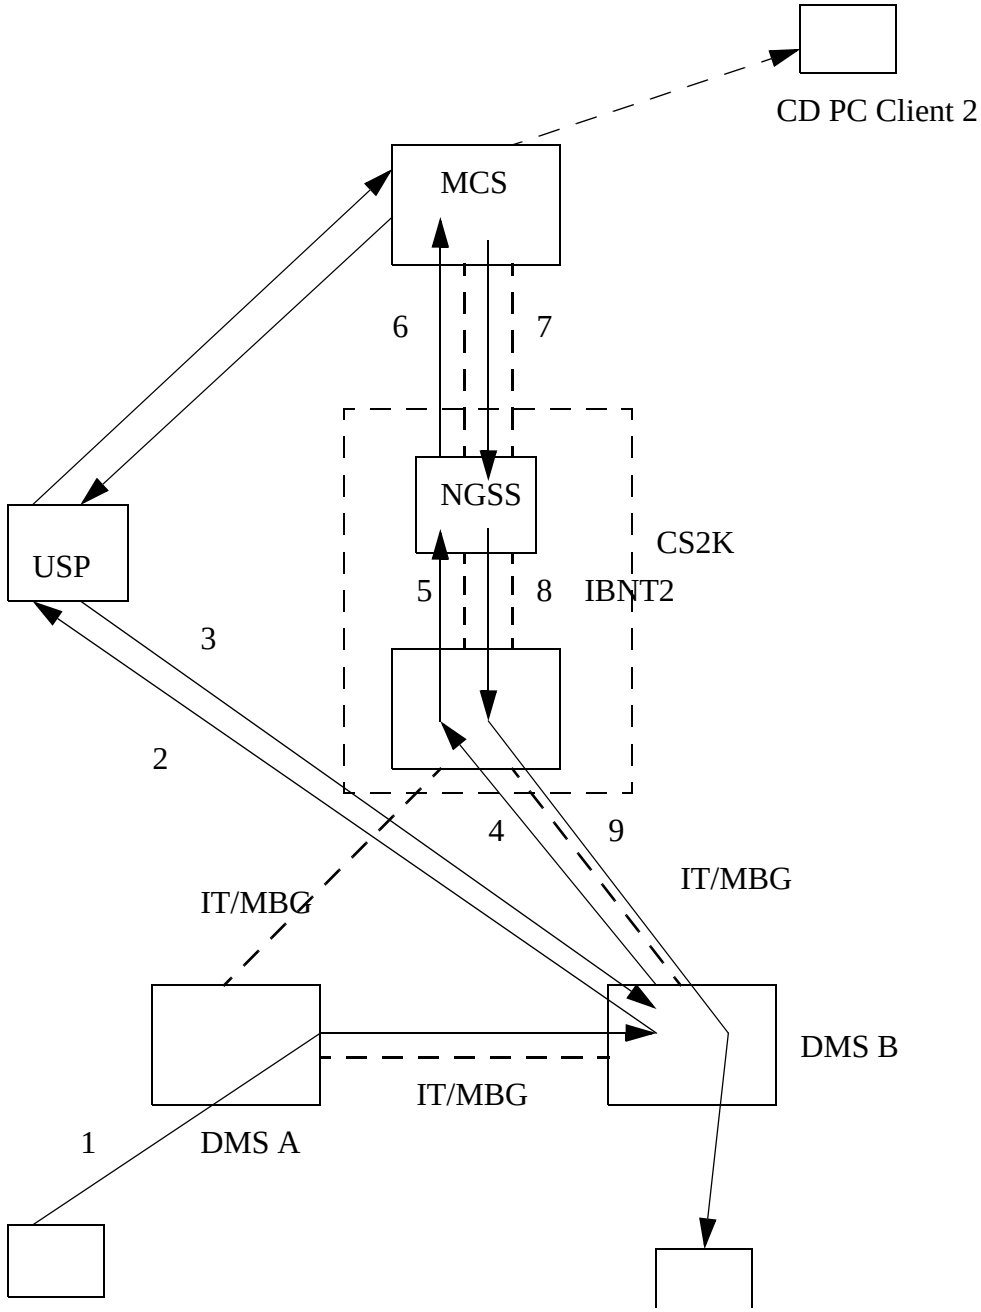

Figure 36 Call from PSTN User to Converged Desktop User

In this call scenario, a PSTN user calls a CD Centrex user; the CD PAD2 display will use the Public Name and Numbers. This display could be something like “PSTN”. The CD PC Client display will also indicate that the caller is outside the Centrex group.

A number of call scenarios exist between parties with at least one CD User involved. A summary of some of the expected display behavior in some of these call scenarios is given in the table below.

Table 2:

Calling Pary	Called Party	Calling PAD	Calling PC Client	Called PAD	Called PC Client
Centrex CD Phone	Centrex phone	dialed digits	No pop up window	Private	N/A
CD - from PC Client	Centrex phone	dialed digits	No pop up window	Private	N/A
CD- from Centrex phone	CD Centrex phone	dialed digits	SIP User ID	Private	SIP User ID
CD - from PC Client	CD Centrex phone	dialed digits	SIP User ID	Private	SIP User ID
Centrex	CD Centrex phone	dialed digits	N/A	Private	Private
CD - not in CD mode	Centrex phone	N/A	dialed digits	Private	SIP User ID
Centrex	CD - not in CD mode	dialed digits	N/A	Private	Private
PSTN	CD Centrex phone	dialged digits	N/A	Public	Public
CD - from Centrex phone	PSTN	dialed digits	N/A	Public	N/A
CD - from PC Client	PSTN	dialed digits	N/A	Public	N/A
CD - not in CD mode	PSTN	dialed digits	N/A	Public	N/A
CD Centrex	CD Centrex	dialed digits	SIP User ID	Private	SIP User ID
Centrex	CD Centrex	dialed digits	N/A	Private	Private
PSTN	CD Centrex	dialed digits	N/A	Public	Public

To support Private/Public Name and Number displays in calls that cross between the DMS Centrex group arena into the MCS SIP domain arena, a combination of translations, including utilization of MBG over IT trunks and provisioning of decicated IBNT2 trunks per Centrex group is used. Additionally, software changes are made on the MCS and the NGSS to map

ISUP NPI/NOA combinations to phone context information in SIP messages between the NGSS and the MCS.

81.2.5 Offer Answer SDP

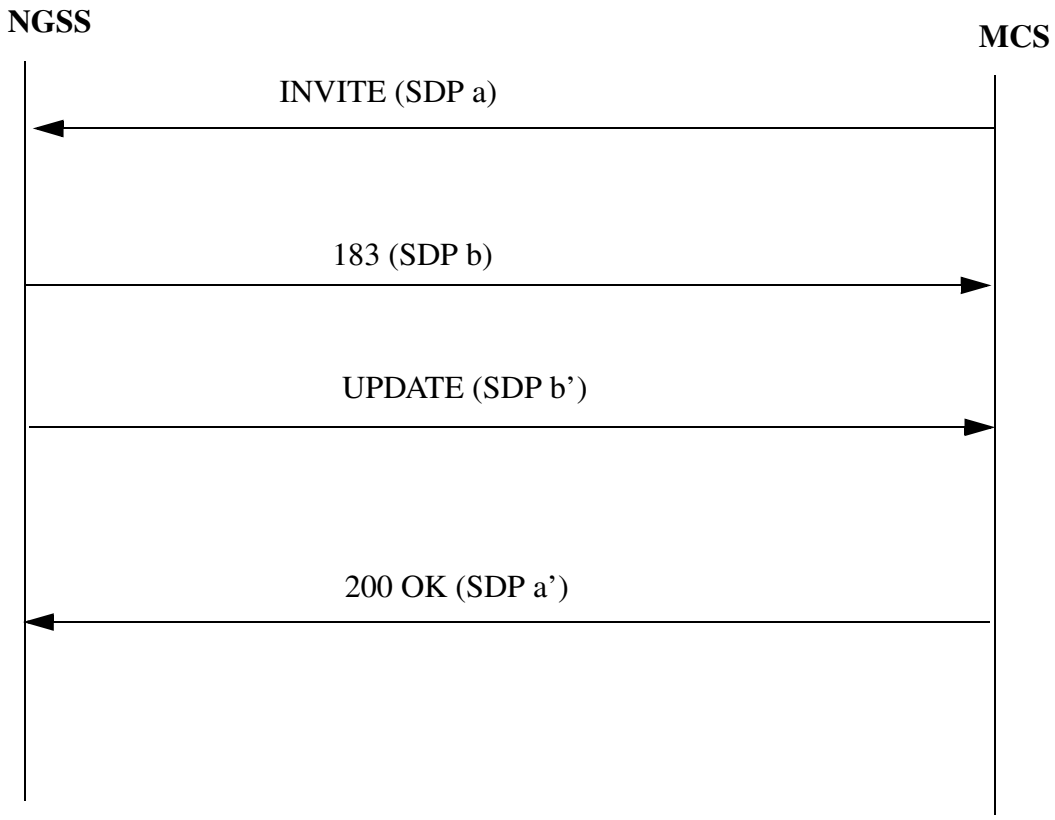
UPDATE method defined by RFC 3311 allows SIP entities to modify session attributes after initial offer answer has been exchanged. The session attributes can be modified before or after answer. Generally UPDATE is used to modify session attributes before answer as most SIP implementations use SIP re INVITE mechanism to modify session attributes after answer.

Currently NGSS sends UPDATE to modify session attributes before answer if the remote server configuration indicates that remote server supports UPDATE method. This is not the right means of deciding when to send UPDATE method. This activity improves on the design of when to send the UPDATE method as follows:

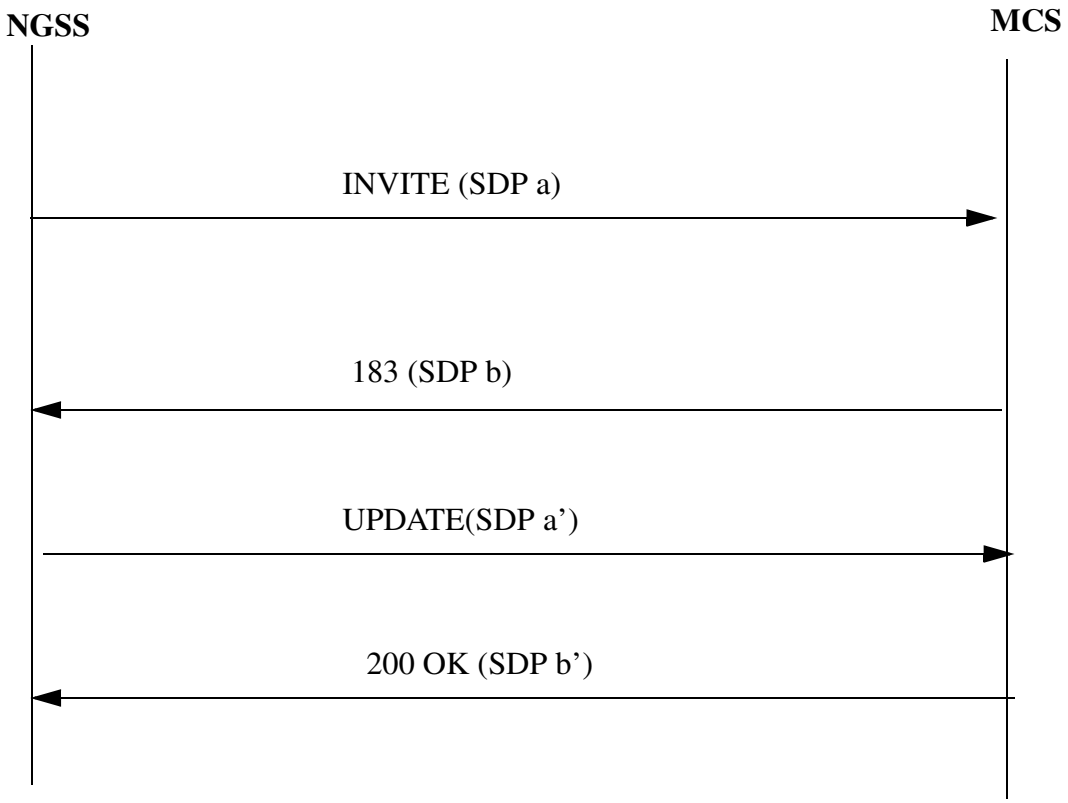
•The remote SIP node will basically indicate through means of Allow header when in a call UPDATE is allowed.
•NGSS will send UPDATE method when the remote server has indicated through messaging that UPDATE is allowed.
•NGSS will indicate that UPDATE method is allowed only after OFFER Answer SDP exchange has been completed.
•Due to backward compatibility with NGSSes prior to the SN09 release, that do not support UPDATE through messaging, UPDATE will still be supported through the GUI.

MCS uses the Allow header to indicate when UPDATE is allowed. NGSS will scan for Allow header for messages from the MCS and indicate in a call data block when UPDATE is allowed.

The call flow below indicates the interaction between the MCS and the CS2K on the usage of the UPDATE method.



a) UPDATE method accepted for processing by NGSS



b) UPDATE method sent out by the NGSS and accepted for processing by MCS

81.2.6 MCS Endpoints and Services

The following are the MCS endpoints and services that this feature will support.

81.2.6.1 MCS Endpoints

- MCS PC Client
- MCS i2002/i2004
- MCS PC Client Set
- RTP Media Portal
- AudioCodes Mediant 2000 SIP PRI Gateway
- Media Application Server
- Sipura IAD (Intergated Access Device)
- Ambit IAD (Intergated Access Device)
- Mediatrix PRI Gateway
- Rel 3.0 PC Client/Client Set

81.2.6.2 MCS Services

- Basic Call/incoming/G711
- Basic Call/outgoing/G711
- Basic Call/incoming/G729A
- Basic Call/outgoing/G729A
- Calling Number Delivery
- Calling Number Delivery Block
- Called Number Delivery
- Called Number Delivery Block
- Calling Name Delivery
- Calling Name Delivery Block
- Redirecting Name Delivery
- Redirection Name Delivery
- Original Called Number Delivery (OCdNo)
- CPL forking (Sim Ring)
- CPL Sequential Ringing
- Call Redirect
- Call Redirect Reason

- Call Reject With Reason
- Call Rejection on Unauthorized Request
- Call park against token
- Call park against user
- Call park auto retrieval
- Call retrieve against token
- Call retrieve against user
- Call Forwarding (CF)
- Call Forwarding Busy (CFB)
- Call Forwarding No Answer (CFNA)
- Call Forwarding Access Code (CFAC)
- Click to Call (C2C)
- Branding
- Hold/Retrieve (with Music On Hold)
- Hold/Retrieve (without Music On Hold)
- Ad-hoc Conferencing and Consultative Call Transfer
- Blind Call Transfer
- Meet-me Conference
- Call Park
- MCS Call Route Advancing
- Long Call Duration (MCS to CS2K)
- E911 (on CS2K)
- Message Waiting Indication (MWI)
- Call Pickup (CPU)
- Converged Desktop

81.2.7 CS2K Endpoints and Services

The following are the CS2K endpoints and services that this feature will support.

81.2.7.1 CS2K Endpoints

- IW-SPM (Interworking Spectrum Peripheral Module) with Legacy Lines
- Motorola CG4500 MTA (NCS)
- Arris TTM202/402 TTM (NCS)

- Mediatrix 1104/1124 (MGCP)
- Askey 4/12/30 port (MGCP)
- Ambit 1/16/32 port & MG1K (MGCP)
- Nuera gateway
- H.323 gateway
- CICM (Centrex IP Client Manager) gateway
- PVG (Passport Voice Gateway)

81.2.7.2 CS2K Services

- Basic Call/incoming/G711
- Basic Call/outgoing/G711
- Basic Call/incoming/G729A
- Basic Call/outgoing/G729A
- 3-Way Call (3WC)
- Message Waiting Indicator - Audible (MWT, STD sub-option only)
- Incoming MCS call to CS2K E911
- Call Forward
- Call Forward with Announcement
- (CFB) Call Forward Busy
- (CFD) Call Forward No Answer
- Call Forward of Call Waiting Calls
- (SCF) Selective Call Forward
- (CFU) Call Forwarding Universal
- Music On Hold (Call Hold)
- (CPK) Call Park
- (CPU) Call Pickup
- (CXR) Call Transfer
- (CWT) Call Waiting
- (CCW) Cancel Call Waiting
- 3 Party Conference
- Meet Me Conference
- (CNAMD) Calling Name Delivery
- (CNAB) Calling Name Delivery Blocking

- (CND) Calling Number Delivery
- (CNDB) Calling Number Delivery Blocking
- Called Number Delivery
- Called Number Delivery Block
- Redirecting Name Delivery
- Redirection Name Delivery
- Original Called Number Delivery (OCdNo)
- (MLH) Multi Line Hunt

81.3 Hardware Requirements or Dependencies

81.4 Software Requirements or Dependencies

81.5 Limitations and restrictions

SN09 CS2K Interworking with MCS 4.0 is not supported.

VRDN architecture will not be supported on SN09 CS2K.

81.6 Interactions

81.7 Glossary

Term	Description
New term	Definition

82: Functional Description(FN): A00009515

82.1 Feature name and Feature ID

A00009515: Out-of-Band Interop with MCS

82.2 Description

This activity will implement the support for Out of Band (OOB) SIP REFER signaling on the Session Server (formally known as NGSS).

REFER is a SIP method, which requests that the recipient REFER to a source provided in the request. It provides a mechanism allowing a party sending the REFER to be notified of the outcome of the referenced request. This can be used to enable many applications, including Click-to-Call.

A REFER placed outside the scope of the dialog created with an INVITE is called and an Out of Band REFER.

Out of Band SIP REFER support will address the following limitations with the current implementation of the MCS application Click-to-Call (C2C)

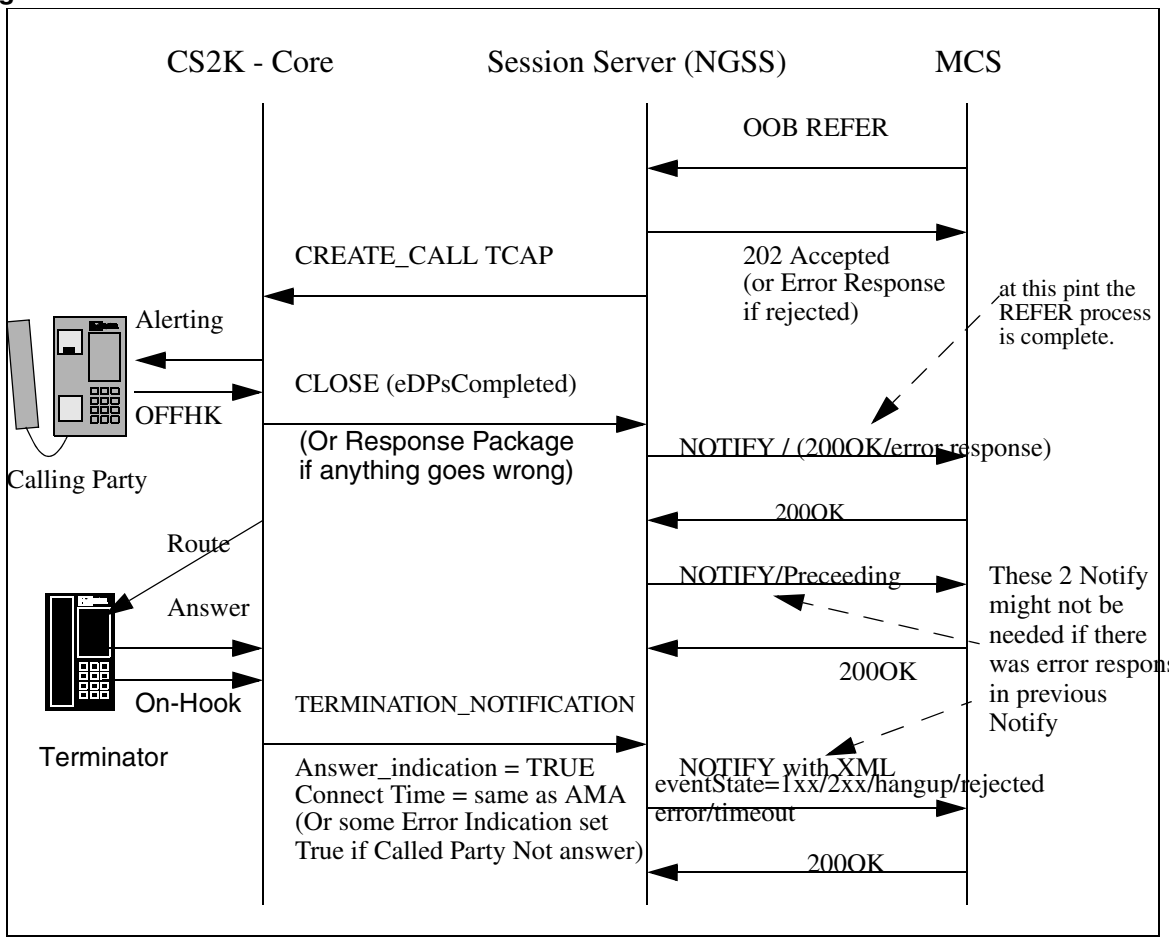
- The originator of the C2C ends up in the Termination Call MOdel (TCM) of the CS2K.
- Originating Call Manager (OCM) services and its feature interactions are bypassed (e.g. auth codes, acct codes, Denied Originations, PIC and other translation related services)
- Unnecessary TCM interactions on the originator of the C2C (like forwarding services.
- OCM updated incorrectly results in Incoming Call Memory (ICM) not being updated correctly, thus some features don’t function as designed.
- Since there are 2 distinct trunk-to-line calls with their media tied to MCS, this can cause issues around ring back and possibly tones, busy signal, even treatments not being heard by the originator. (The originator of the MCS call is already answered so the ringback request from the terminator is not propagated to the real originator).

- Billing is not captured correctly, since the call comes to the caller as an incoming terminating call rather than outgoing originating call.

82.2.1 Click-toCall flow using the new OOB REFER functionality

Following is a flow that illustrated the operation of C2C using the OOB REFER implementation as shown in Figure 1.

Figure 1 Click To Call Call Flow



1. Client invokes C2C on the MCS

2. MCS sends a OOB REFER msg to the Session Server. The REFER contains the following information which will be used in CreateCall NCAS message parameters:

- Mandatory Parameter - CallingPartyId (ReferBy): The DN of party A which is the logical originator who will be referred to Party B. CallingPartyId must be 10 digits
- Mandatory Parameter-CalledPartyId (ReferTo)
- Optional Parameter - ChargeNumber (ReferBy)

3. Session Server receives the OOB REFER request. It parses it and verifies that the REFER is NOT associated with any existing call context and thus it is an OOB REFER. Remote Server validation (provisioning data) is also performed at this point.

4. If the OOB REFER is accepted (i.e. passed the validation and authentication), the Session Server will send a 202 Response to the MCS. The Session Server responding to a REFER method will return a 400 (Bad Request) if the request contained zero or more than one Refer-To header field values.

5. NGSS then maps the REFER request to a create-call TCAP message with a Send_Notification attachment and sends it to the CS2K core via a NCAS link. For detailed description of NCAS link please see the documentation for the NA09 Activity A00007544.

The TCAP create-call is processed in the core as implemented for AIN under NA013 Activity A59011901.

6. A Create Call request is accepted by an analog user going off hook. It is rejected by the user not responding to the notification before a Create Call Timer (TCC) expires.Or if Create Call message has fatal protocol error; Create Call has invalid information in the parameters; Calling Party busy; SOC option is idle, etc., Session Server would receive some response back with cause reason. In this case, a NOTIFY message with appropriate payload content is sent to MCS OOB REFER process is over. Here is example NOTIFY with 503 service unavailable in the payload. Refer to the following table for the mapping between response of Create Call to SIP messages.

Table 1: Create Call response message to SIP response mapping

	Create-Call Response	**Mapping to SIP**
Termination_Notification	Answer_Indication	200OK
Termination_Notification	Busy_Indication: Destination Out of Order	502 Bad GAteway
Termination_Notification	Busy_Indication: User Busy	486 Busy Here
Termination_Notification	Busy_Indication: No Route to Destination	503 Service Unavailable
Termination_Notification	Busy_Indication: No Circuit Available	503 Service Unavailable

	Create-Call Response	Mapping to SIP
Response Package	Protocol Error: Missing Mandatory Parm	400 Bad Request
Response Package	Report Failure: CallingInterfaceBusy	486 Busy Here
Response Package	Report Failure: InappropriateUserInterface	484 Address Incomplete (if Calling Party is invalid) 503 Service Unavailable (if bearer compatibility)
Response Package	Report Failure: ResourceUnavailable	503 Service Unavailable
Response Package	Application Error: Missing Conditional Parm	503 Service Unavailable
Response Package	Application Error: Unexpected Communication	503 Service Unavailable
Response Package	Report Failure: RateTooHigh	503 Service Unavailable

7. When the core detects the user going off hook, it sends a CLOSE message to the Session Server with the cause value of eDPsCompleted and proceeds to route the call to the CalledPartyId.

8. Session Server decodes the CLOSE TCAP message. A NOTIFY/ 200OK msg is sent to the MCS indicating that the OOB REFER process is now complete. Subscription/context are closed at this point. Example of the NOTIFY msg being sent to the MCS and the 200OK response is as follows:

9. Once the 200OK is received by the Session Server another NOTIFY msg, this time with an XML event package, will be sent to the MCS to indicate that the call is proceeding. The Call-ID in this NOTIFY msg will be the same as in all the prior messages.

10. When the call returns to the NULL PIC, the core will send a Termination Notification msg to the Session Server with an appropriate termination indicator. If the call was answered by the Called Party the termination indicator would have Answer_Indication set to TRUE (Called Party has answered the call) and the connect time equal to the elapsed time of the call (same as the AMA record).

11. Once the Termination Notification message is received, Session Server will send the final NOTIFY to the MCS indicating that the call has been completed. In the event that the Answer_Indication is set to TRUE that notify msg will contain an events package indicating the event state of hangup.

82.2.1.1 Successful OOB Refer Message Flow

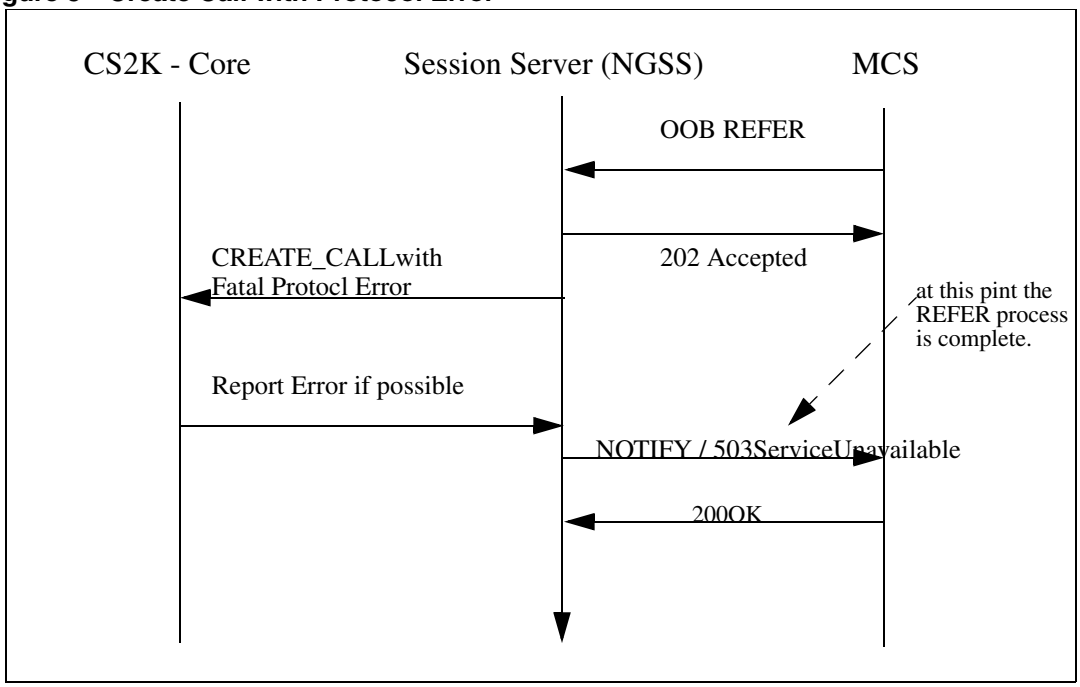
82.2.1.4 Create Call with Protocol Error

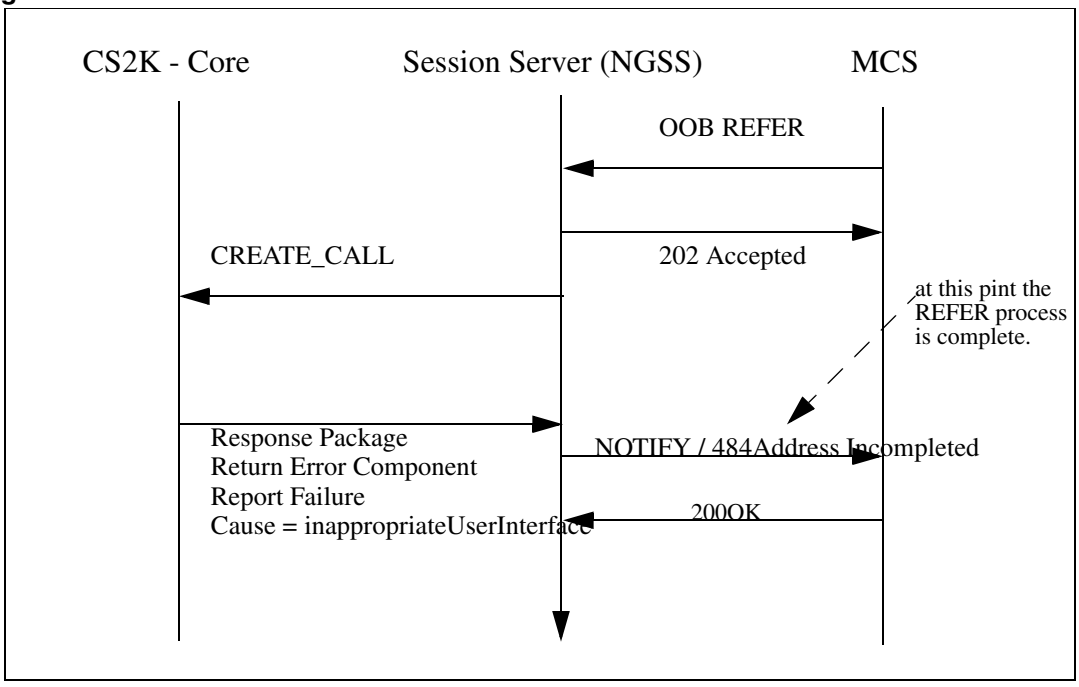
Figure 5 Create Call with Protocol Error



If a Create Call message contains a Protocol error, then it will be reported to the SCP if appropiate. NGSS will send final Notification to MCS with 503 Service Unavailable.

82.2.1.5 Create Call with Invalid Calling Party ID

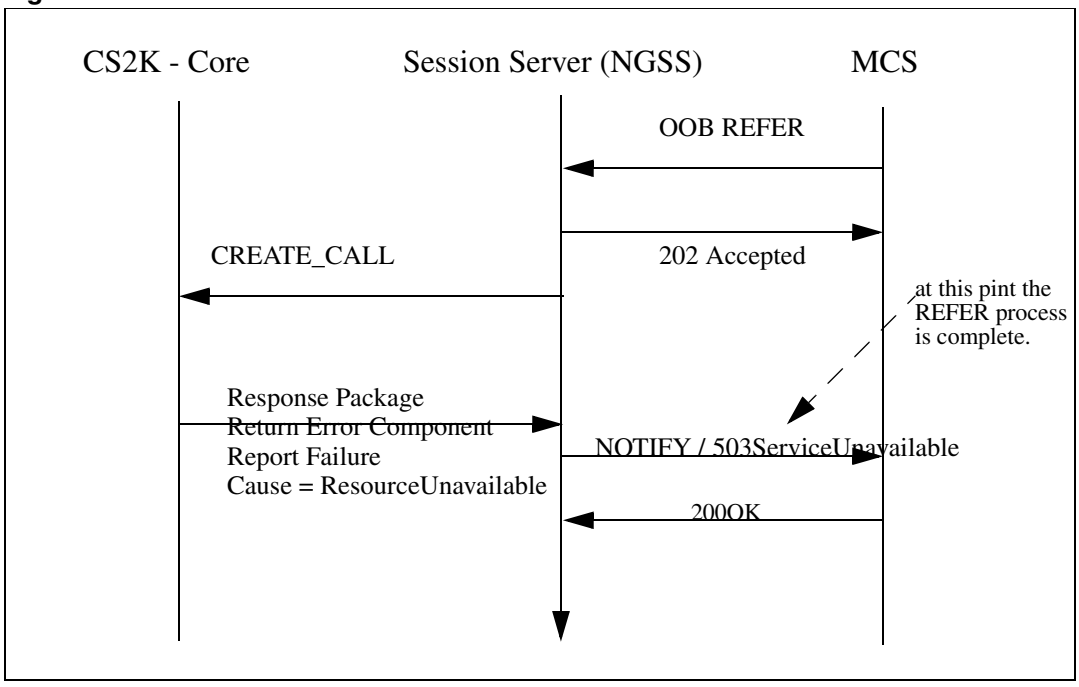
Figure 6 Create Call with Protocol Error



If a Create Call message contains a Protocol error, then it will be reported to the SCP if appropiate. NGSS will send final Notification to MCS with 484 Address Incompleted if it is Calling Party Invalid, or Notify with 503 Service Unavailable if it is invalid Bearer capability.

82.2.1.6 Create Call with Network Resource Unavailable

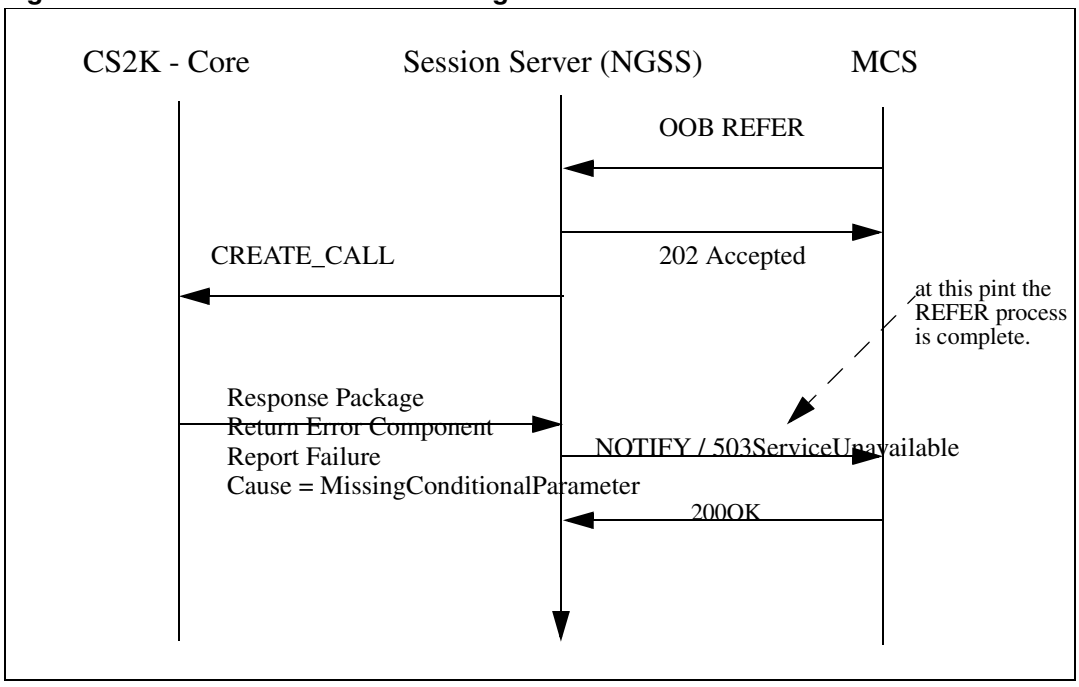
Figure 7 Create Call with Network Resource Unavailable



If Response Package returns failure as Resource Unavailable, NGSS would send final Notify message with 503 Service Unavailable to MCS.

82.2.1.7 Create Call with Fatal Missing Conditional Parameter

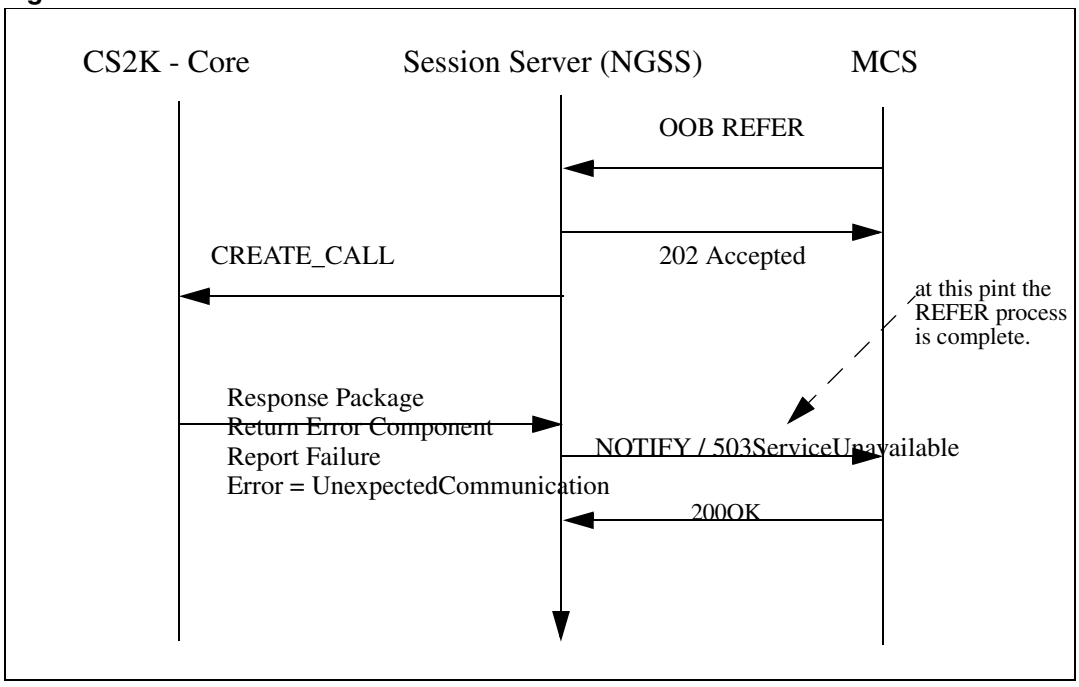
Figure 8 Create Call with Fatal Missing Conditional Parameter



If a Create Call message is determined to be missing an Optional parameter which is required then it is reported to the NGSS as a fatal Application Error with error as MissingConditionalParameter. NGSS then would send final Notify message with 503 Service Unavailable to MCS.

82.2.1.8 Create Call when SOC AIN00271 is IDLE

Figure 9 Create Call when SOC is IDLE



If a Create Call message is received when the SOC Option AIN00271 is IDLE then an Application Error with Error Cause set to Unexpected Communication is sent to NGSS. NGSS then would send final Notify message with 503 Service Unavailable to MCS.

82.3 Hardware Requirements or Dependencies

This feature doesn't introduce any new hardware requirements or dependencies

82.4 Software Requirements or Dependencies

Create Call must be enabled by SOC code AIN00271.

82.5 Limitations and restrictions

Following are the restrictions and limitations that apply to this feature;

- SIP Lines are not supported.

- NGSS standalone configuration, where the NGSS functions as converter from OOB REFER and TCP and the core is not running succession software and thus is not supported.
- List of agents not supported by this feature can be found in section 2.6.6 “Agent Support for Create Call”
- OFF Hook Delay Trigger (part of Info_Collected TDP) is not supported. See section 2.6.5. Interaction with AIN Triggers.
- TCAP messages from the CS2K to the Session Server can be lost during various maintenance actions (restarts, swacts.) which in turn could cause the Call Log on the MCS not to be updated correctly.

82.6 Interactions/Interworking

82.6.1 Feature Interactions with the Originator (CallingParty)

82.6.1.1 Originating Restriction Features

When the originator has one of the following call originating restrictions, the **Create Call request is rejected** by sending the NGSS a Failure message with failureCause=inappropriateCallingInterface:

DOR (denied Origination)

SUS/RSUS (suspended/requested suspension)

In addition to the above originating restriction features, the following originators also result in failing the Create Call request (a Failure message with failureCause=inappropriateCallingInterface is sent to the SCP):

Hotline Features AUL (automatic line), and MAN (Manual Line)

A line with the ESL (Emergency Service Line) option

one of the following MADN groups:

MADN SCA (Single Call Arrangement)

MADN MCA (Multiple Call Arrangement)

MADN EXB (Extension Bridge)

MADN CACH

ACD

UCD

MeetMe Conference

Non Resident DN

A line with BC (Bearer Capability) option with values other than SPEECH or 3_1KHZ.

When the originator has one of these features active, it is considered interface busy thus no alerting is provided to the originator:

all variants of Call Waiting, including TCW (Talking Call Waiting)

all variants of Hold

82.6.1.2 Terminating Features on the Originator

When alerting the originator, terminating features **are not activated** since the alerting is a treatment that applied to the originator indicating the Create Call request, not a call that is terminating on the originator. These terminating features include:

- All variants of Call Forwarding
- SCMP (Series CoMPletion)
- Termination Restrictions like DIN (Denied Incoming), DTM (Denied Terminating), DND (Do Not Disturb), MBK (Make Busy Key), MSB (Make Set Busy), MSBI (Make Set Busy Intragroup), PLP (PLug uP), SUS/RSUS (suspended/requested suspension) and RMB (Random Make Busy).
- EBCR (Enhance Busy Call Return)
- Intercept Feature like FLEXI (Flexible Intercept)
- Messaging Features like CSMI (Call Screening/Monitoring Intercept), EMW (Executive Message Waiting), FTS (FAX-Thru Service), ISA (In-Session Activation), SCM (Selective Call Messaging), SDS (Special Delivery Service), SODS (Special Offering Decoupling of SDS), MWT (station Message WaiTing) and UVM (universal Voice Messaging).
- Call Message Feature for RES
- Call Pickup

- Hunting Features (a member of a hunt group as the originator is alerted for the Create Call request if not busy, however, if it is busy, no hunting is done and the case is handled as the originator being busy.)
- Hunt Group Overflow Routing like LOD (Line Overflow to DN) and LOR (Line Overflow to Route)
- DLCM (Dual Line Call Management)
- SimRing (Res Simultaneous Ringing)
- ACRJ (Anonymous Caller ReJection)
- SCA (Selective Call Acceptance)
- SCRJ (Selective Call ReJection)
- SCF (Selective Call Forwarding)

82.6.1.3 Account Codes

Attempt to activate Account Codes (First or Last flavours) features prior to Called Party answers are denied. That is, if a Create Call is requested to originate from a line that requires Account Code, the Account Code is bypassed and the call is routed to the Called Party without the input of the Account Code.

The Account Code Voluntary feature shall be permitted to activate after flashing during an active call established through the Create Call functionality.

Note: Warning! It is assumed that the SCP/Adjunct is a "Trusted Node" and has authenticated the user request for Create Call functionality. The SCP/Adjunct provides Account Code data collection capabilities if the Service Provider deems them necessary.

82.6.1.4 Authorization Codes

Attempt to activate Authorization Codes (First or Last flavours) features prior to Called Party answers are denied. That is, if a
Create Call is requested to originate from a line that requires Authorization Code, the Authorization Code is bypassed and the call is routed to the Called Party without the input of the Authorization Code.

The Authorization Code Voluntary feature shall be permitted to activate after flashing during an active call established through the Create Call functionality.

Note: Warning! It is assumed that the SCP/Adjunct is a "Trusted Node" and has authenticated the user request for Create Call functionality. The SCP/Adjunct provides Account Code data collection capabilities if the Service Provider deems them necessary.

82.6.1.5 Authorization Code Immediate Dialing (ACID)

The ACID feature removes the seven second pause between the input of authorization codes and second dial tone. When an IBN subscriber dials a correct authorization code, including the correct security digits, the ACID feature assumes that no more authorization code digits are to be dialed. It then proceeds immediately to the next stage of call processing without waiting for an octothorpe (#) or interdigit time-out.

The interactions with this feature is the same as Create Call interactions with Authorization Codes.

82.6.1.6 Station Specific Authorization Codes (SSAC)

SSAC has the same interactions as authorization codes.

82.6.1.7 CRL (Code Restrictions)

Any DN that is blocked for the customer group through CRL is not blocked when a call is routed to that DN by the Create Call functionality.

82.6.1.8 SOR (Station Origination Restrictions)

The SOR feature determines whether the call should be restricted. SOR restrictions fall into one of the following four categories:

— calls permitted based on NCOS

— only intragroup calls or calls on an exception list are allowed

— only intragroup calls are allowed

— only calls on the exception list are allowed

— no calls are allowed

82.6.1.9 Toll Restriction Features

At the alerting originator phase, the originator is not checked against Toll Restrictions, that is, even if the originator has Toll Restrictions, the SSP will still alert the originator. When the originator accepts the call, the SSP then attempts to route the call to the called party -- this is when the Toll Restrictions are checked and applied to the call.

Toll Restrictions include:

- CTD (carrier toll denial)
- Equal Access Enhanced Carrier Toll Denial
- FCTDNTER (InterLATA Full Carrier Toll Denial)
- TDN (Toll Denial)
- TDV (Toll Diversion)

82.6.1.10 Features Treated as Interface Busy

When the originator has one of these features active, it is considered interface busy thus no alerting is provided to the originator:

- all variants of Call Waiting, including TCW (Talking Call Waiting)
- all variants of Hold

82.6.1.11 Call Waiting During Alerting Originator

When a call is terminating on an interface which is being notified as an originator of a previously received Create Call message, the SSP shall treat the call as terminating party busy. All call waiting features including SCWID (Spontaneous Call Waiting Identification, DSCWID (SCWID with Disposition) are not activated.

82.6.1.12 No Barge-in on Create Call

The SSP do not Barge-in on a call while attempting to service a Create Call request. In other words, when the originator is being alerted for a Create Call request, Barge-In features like executive busy override (EBO) and directed call pickup with barge in (DCBI) cannot be activated.

82.6.1.13 Feature Activation after Originator Accepts Create Call

Once the originator accepts the Create Call request by going offhook, the originator is able to activate any features that can be activated through normal call setup.

82.6.1.14 Distinctive Ringing Features

When optional parameter ControllingLegTreatment is included in the Create Call message, the value specified in this parameter overrides the switch based Distinctive Ringing features.

82.6.1.15 Feature Activation after the Calling Party accepts Create Call

Once the originator accepts the Create Call request by going offhook, the originator is able to activate any features that can be activated through normal call setup.

82.6.2 Feature Interaction during routing to Called Party

82.6.2.1 Terminating Features

Terminating features on the Called Party are activated and function the same way as the call has been initiated by the originator through going offhook and dialing the digits.

82.6.2.2 Calling Number/Name Display/Blocking

The presentation status in the Calling Party ID in the Create Call message overrides calling number/name display/blocking features.

82.6.2.3 Distinctive Ringing Features

When optional parameter PassiveLegTreatment is included in the Create Call message, the value specified in this parameter overrides the switch based Distinctive Ringing features.

82.6.2.4 UCD (Uniform Call Distribution) Call Queuing

If the Called Party ID maps to a station in a UCD group, the call created through the Create Call functionality is terminated to that station.

82.6.2.5 Direct Inward System Access (DISA)

when the Called Party ID maps to a DISA DN, it behaves the same way as if the user had dialed the DN.

82.6.2.6 Preset Conference

A call can be routed to a Preset conference DN through a Create Call request.

82.6.2.7 MeetMe Conference

A call can be routed to a MeetMe conference DN through a Create Call request.

82.6.2.8 Expensive Route Warning Tone

When routing to the Called Party, the Expensive Route Warning Tone is not heard.

82.6.2.9 Flash

When routing to the Called Party, before the call terminates on the Called Party, flash is not allowed. Flash after terminating on the Called Party is allowed.

82.6.2.10 Flexible Calling (FC)

When routing to the Called Party, before the call terminates on the Called Party, FC is not allowed. FC after terminating on the Called Party is allowed.

82.6.2.11 PVN (Private Virtual Network)

While routing to the Called Party, attempting to start the PVN feature results in FNAL treatment to be applied to the call.

82.6.2.12 MCDN (Message Center Directory Number)

While routing to the Called Party, attempting to start the MCDN feature results in FNAL treatment to be applied to the call.

82.6.2.13 E800

If the Called Party ID in the Create Call message is an E800 number, the SSP shall activate the E800 service and query the E800 database.

82.6.2.14 AIN TFS

If the Called Party ID in the Create Call message is an AIN TFS number, the SSP shall query the SCP.

82.6.2.15 Emergency 911

If the Called Party ID in the Create Call message contains digits '911', which correspond to the emergency service, the SSP shall route the call using the E911 service.

82.6.3 Interactions with AIN Triggers

- **When Alerting the Calling Party** - When alerting the originator for a Create Call request, all AIN triggers encountered (e.g., terminating triggers like TAT, T_No_Answer and T_Called_Party_Busy triggers) are ignored and queries to the SCP are not sent.
- **Calling Party goes OFFHK** - When the originator accepts the Create Call request by going offhook, any AIN triggers encountered at the Orig_Attempt TDP and Info_Collected TDP are ignored and queries to the SCP are not sent. **Off Hook Delay Trigger** is part of the Info_Collected TDP and thus will be IGNORED.
- **Routing to Destination** - After the originator accepts the call, the CS2K attempts to route the call to the called party of the Create Call message. During the routing phase, any triggers that may occur result in queries to be sent to the SCP.

82.6.4 Agent Support for Create Call

The Calling Number in a Create Call message must be a local line agent. This is by definition of the Create Call Message. Only agents supported by AIN may be the Calling Number. The following additional restrictions are placed upon which line agents are supported as Create Call Originators:

- ISDN PRI agents are not supported (PRI is considered to be a trunk)
- ISDN BRI agents are not supported
- Coin lines are not supported
- Attendant Consoles are not supported
- Virtual Agents are not supported.
- ADSI terminals are supported as an analog agent
- Party lines are not supported.
- Hunt group members are supported, but no hunting is done.

82.6.4.1 TOD (Time Of Day routing)

The route taken by Create Call can be affected by Time of Day(TOD) Routing.

82.6.4.2 Simplified Message Desk Interface (SMDI)

The Called Party in the Create Call message can be a line served by SMDI.

82.6.4.3 Series Completion (SCMP)

A call created through the Create Call functionality can terminate to an SCMP group and does not affect the SCMP terminating algorithm.

82.6.4.4 Hunt Groups

If the Called Party ID in the Create Call message corresponds to one of the following Hunt Groups, then the call is terminated on first available member of the Hunt Group:

- BNN (Bridged Night Number)
- DLH (Distributed Line Hunt)
- DNH (Directory Number Hunt)
- KSH (Key-Set Short Hunt Group)
- MLH (Multiline Hunt)
- MPH (Multiple Position Hunt)
- NSDN (Night Service Directory Number)

82.6.4.5 Feature Groups

A call established through the Create Call functionality can route either as FGB, FGC or FGD.

A call established through the Create Call functionality can not be routed as FGA.

82.6.4.6 MADN (Multiple Appearance Directory Nymber)

When the Called Party ID included in the Create Call message maps to one of the following MADN group, the call terminates on the MADN group:

- MADN SCA (Single Call Arrangement)
- MADN MCA (Multiple Call Arrangement)
- MADN EXB (Extension Bridge)
- MADN CACH

82.6.4.7 SimRing

When CalledPartyID parameter in the Create Call message is a pilot DN, then SIMRING is activated and the Call proceeds normally.

82.6.4.8 PLP (PLug uP)

When the Called Party has the PLP feature activated, a call created through the Create Call functionality is not allowed to terminate on the Called Party.

82.6.4.9 SUS/RSUS (suspended/requested suspension)

When the Called Party has the SUS/RSUS feature activated, a call created through the Create Call functionality is not allowed to terminate on the Called Party.

82.6.4.10 RSDT (restricted dial tone) with state in-effect

When the Called Party has the RSDT feature activated, a call created through the Create Call functionality is not allowed to terminate on the Called Party.

82.6.4.11 CLASS Outgoing Call Memory

When a call is originated via the Create Call request, the SSP does not update the outgoing Memory Slot (OMS), regardless whether or not the call is diverted through triggering while routing to the Called Party.

82.6.4.12 LNR (Last Number Redial)

Attempt to invoke LNR on a call established through the Create Call functionality shall result in calling the number the originator dialed before the Create Call request.

82.6.4.13 AR (Automatic Recall)

Attempt to invoke AR on a call established through the Create Call functionality shall result in calling the number the originator dialed before the Create Call request.

82.6.4.14 ACB (Automatic Call Back)

When an attempt to establish a call through a Create Call request fails due to the Called Party's interface busy status, invoking ACB from the originator of the Create Call message shall result in calling the number the originator dialed before the Create Call request.

82.6.4.15 Ring Again Features

- **Call Back Queuing (CBQ)**: CBQ cannot be invoked when the call encounters a busy facility while routing the Called Party of a Create Call message.

  Note: CBQ (also known as on-hook queuing) provides a ring back to the on-hook calling line when a facility that the call is queued against becomes available. CBQ can be activated by the caller after receiving no circuit treatment, expensive route warning tone, or during the off-hook queue tone or announcement.

- **Nodal ring again (RAG)**: Attempt to invoke RAG on a call established through the Create Call functionality shall result in calling the number the originator dialed before the Create Call request.
- **Network ring again (NRAG)**: NRAG is applicable when the ring again feature is networked across different switching nodes. From a user point of view, NRAG and RAG operate the same way for Create Call.

82.6.4.16 Dynamic Control Routing (DCR)

Dynamic Control Routing may encounter while routing to the Called Party.

82.6.4.17 ACD (Automatic call distribution) Termination

Automatic call distribution (ACD) permits calls to be evenly distributed to a number of designated ACD agent positions. When all positions are busy, new calls are queued and a ringing tone or announcement can be returned to the caller.

A call can be routed to an ACD DN through the Create Call request and ACD functionality is not impacted.

Parameter Calling Party Id in the Create Call message is not used to update the display of EBS sets with the ACD option.

82.6.4.18 SMDR (Station Message Detail Recording)

All calls that would normally generate SMDR records will continue to do so when the call is created through the Create Call functionality.

83: Functional Description(FN): A00009520

83.1 Feature name and Feature ID

Feature ID: A00009520

Title: Trunk blocking tools for MG4K and GWC on SN09

83.2 Description

When a MG4K-ATM or GWC goes into overload, some trunks on that node need to be busied to offload traffic. In the current system, it provides the capability to busy whole trunk group or all members on a specific MG4K-ATM/GWC node. However, there is no way to busy specific trunks on an individual MG4K-ATM/GWC.

This feature enhances the existing post command under MAPCI TTP level to provide the following functions:

- Busy a specific trunk group on an individual MG4K-ATM gateway;
- Busy a specific trunk group on an individual GWC.

A new post type ‘I’ is introduced under MAPCI TTP level by this feature. When post command with type ‘I’ is entered in the command, it posts the trunks in the existing post set. If there is no existing post set, it returns error. The following is the error example:

The following is an example on how to post the trunk members of TRUNK_EXAMPLE on GWC 32.

```
                IOD          PM    CCS    Lns    Trks   Ext    APPL
                OCC  B       PMLOAD 3   RS  SYSB    42C..  2Crit   .

12 NEXT        TTP:
13 RLS
14 Ckt_
15 TrnslVf_
16 StkSdr_
17 Pads
18 Level_
  TESTER
Time  15:32  > POST D GWC 32; POST I G TRUNK_EXAMPLE
```

1. *POST D GWC 32; // create a post set which contains all the trunks on GWC32;*
2. *POST I G TRUNK_EXAMPLE; // Post only the trunks whose CLLI are TRUNK_EXAMPLE in the post set.*

Only post type ‘D’ and ‘G’ are allowed to follow the type ‘I’. Only DEQ name ‘GWC’ and ‘SPM’ are allowed to follow the post type ‘D’ if it is after the type ‘I’. This feature is based on the existing BSY functions for trunks on GWC and SPM.

The trunks that supported by this feature are ISUP, PTS and PRI on GWC and MG4K-ATM.

83.3 Hardware Requirements or Dependencies

N/A

83.4 Software Requirements or Dependencies

N/A

83.5 Limitations and restrictions

- Only trunks on GWC and MG4K-ATM are supported by this feature.

83.6 Interactions

- A set of trunks must be posted prior to to ‘POST I’ command.

83.7 Glossary

84: Functional Description(FN): A00009530

84.1 Feature name and Feature ID

A00009530 - “H248 & xUA NAT traversal for CPE Gateways”

84.2 Description

Introduction

Small trunk gateways, such as the Audiocodes Mediant 2000 (M2k), are being deployed as Customer Premises Equipment (CPE). This is being done in order to connect TDM PBXs to packet telephony networks, as we expect that there will be many such older TDM PBXs in service for a number of years to come.

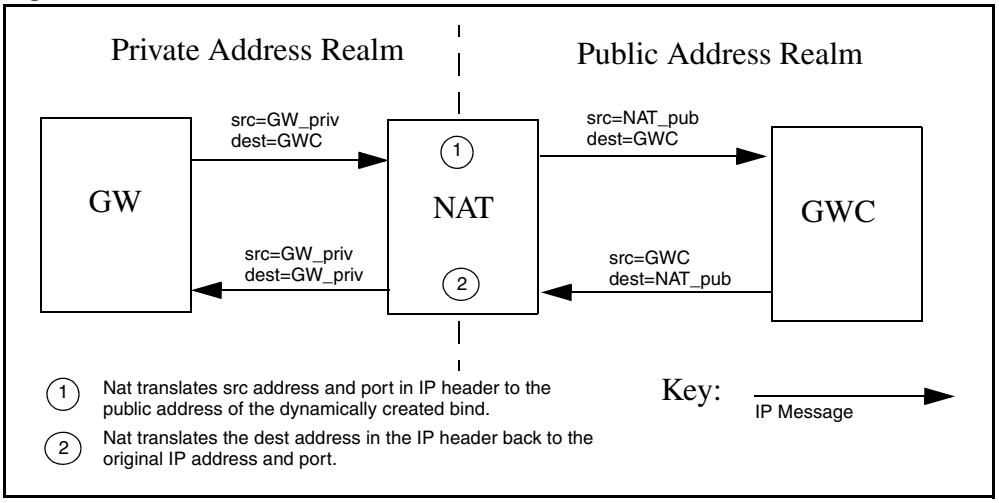
Various protocols are used to control these gateways. Within the scope of this feature, H.248 is used for control of the bearer path. Call control signalling can be via protocols such as ISDN PRI, or DPNSS. These signalling protocols are backhauled from the gateway to the CS2k over an SCTP connection. Currently, neither the H.248, nor the SCTP protocol can work over a NAT without special datafill in place. This feature will enable these protocols to work automatically when the gateway is located behind a NAT. Note that the CS2k and GWCs must remain within the core network.

84.2.1 Operation

NAT systems are in common use throughout IP networks today. They allow use of private addresses within a network by translation of IP addresses within the IP header. CPE gateways may well be connected via a NAT, so this needs to be a supported configuration for the CS2k.

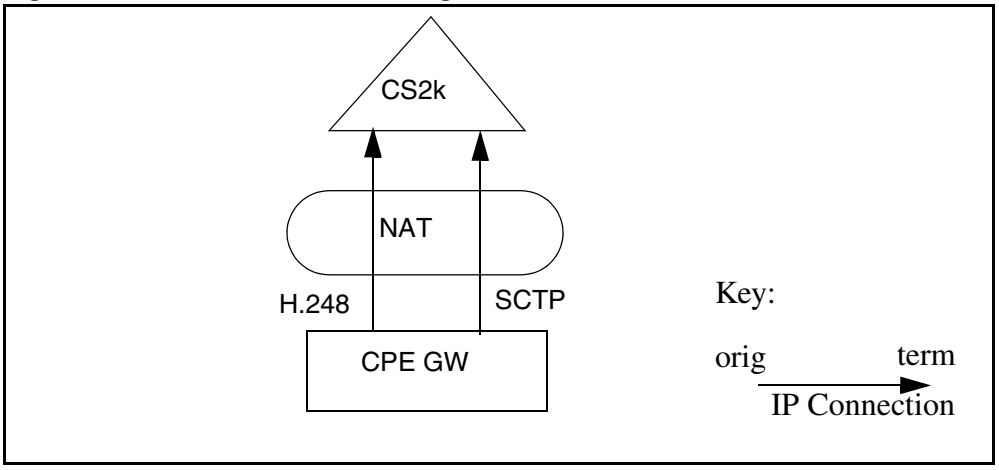
Figure 1 illustrates a simple case of NAT operation. The NAT creates a dynamic bind in response to the initial message from the gateway. This allows messages to pass in both directions between gateway and GWC. The NAT bind will be removed if there is no traffic over it for a specified period of time. In order to avoid this happening to an established connection, we need to ensure a minimum traffic level over the link. SCTP has an inbuilt heartbeat mechanism which will perform this function. For H.248, the gateway should use the Inactivity Timeout package to do this.

Figure 1 CPE GW Connected via a NAT



Without special NAT configuration, incoming IP connections are not possible to a host behind a NAT. So, in order for a connection to traverse a NAT, it must originate from within the NAT zone. For us, this means that the connections must be initiated by the gateway rather than the CS2k. The figure below shows both H.248 and SCTP connections being originated from a CPE gateway.

Figure 2 Functional Behavior Diagram



In a normal, non-NAT, setup, H.248 connections are already initiated from the gateway, but SCTP connections are done from GWC to GW. This is changed by this feature for gateways behind a NAT.

When the CS2k receives an incoming connection from the gateway, the connection will appear to be from the NAT's public IP address, rather than the gateway. As we cannot be sure of this address when provisioning the gateway, we need to rely on the GWC to determine the IP address and port by extracting them from the IP headers. This process is known as IP auto discovery, and has already been implemented for small line gateways using the MGCP protocol.

This was done by feature 59034470 - “CS2000 Support for IP Discovery”. When an IP address of 0.0.0.0 or a port of 0 is provisioned for a gateway, the GWC will attempt to automatically discover the true values. This feature extends support for this functionality to the H.248 and SCTP protocols.

84.2.2 H.248 Support

In order for H.248 to traverse a NAT, the following must be set up:

- The MID of messages sent by the gateway must match the provisioned name of the gateway on the CS2k. The FQDN of the gateway is suggested for use here.
- The gateway should NOT include the “AD” (ServiceChangeAddress) parameter in the H.248 ServiceChange message the it sends to the GWC.
- The GW must be provisioned with an IP address of 0.0.0.0 unless the public IP address that the NAT will use is known.
- The GW must be provisioned with a H.248 protocol port of 0 unless the public port that the NAT will use is known.
- The NAT/VPN that the GW resides behind must be specified when the GW is provisioned, via the 'adjacent Network Zone' field in the 'associate Gateway' dialog.
- The gateway must support the H.248 Inactivity Timeout package, and use it to maintain a minimum traffic level over the NAT. This traffic level must be sufficient to prevent the NAT bind timing out.

84.2.3 SCTP Support

In order for SCTP to traverse a NAT, the following must be set up:

- The gateway must attempt to initiate the SCTP connection to the GWC.
- The INIT message used to initiate the SCTP association must contain a Host Name Address parameter. The contents of the parameter must match the provisioned name of the gateway on the CS2k.
- The GW must be provisioned with an IP address of 0.0.0.0.
- The NAT/VPN that the GW resides behind must be specified when the GW is provisioned, via the 'adjacent Network Zone' field in the 'associate Gateway' dialog.
- The gateway must send SCTP heartbeat messages in order to maintain a minimum traffic level over the NAT. This traffic level must be sufficient to prevent the NAT bind timing out.

84.3 CS2M Provisioning Support For NAT Traversal

The CS2M platform is modified to allow the provisioning of adjacent Network Zones against the Audiocodes GW. This is done by enabling existing functionality currently supported for small line and H.323 type GWs.

For completeness the following figures show the newly enabled functionality for the Audiocodes GW.

Figure 3 shows the Associate Media Gateway dialog for the Audiocodes GW. The Internet Transparency selector box is enabled allowing an adjacent Network Zone to be optionally associated with the GW.

Figure 4 shows the GW list panel from the CS2M provisioning GUI. Here an Audiocodes GW has been previously added with an adjacent ITRANS Network Zone. The “Adj ITRANS MB” field is showing the Network Zone associated with the GW.

Figure 5 shows the input XML for the assocMG OSSGate interface. Here the itransMiddleboxName tag value pair has been specified to request an ITRANS Network Zone be associated with the new AUDIOCODES GW.

Figure 6 shows the Change GW - Change Adjacent ITRANS Network Zone dialog.

Figure 7 shows the changeAssocMB OSSGate XML interface as used to change the Network Zone associated with a GW.

84.4 Hardware Requirements or Dependencies

Not applicable.

84.5 Software Requirements or Dependencies

The software load on the gateway must be capable of fulfilling the gateway requirements in the “H.248 Support” and “SCTP Support sections above. The 4.6 version of software for the Audiocodes Mediant 2000 gateway will satisfy these requirements.

84.6 Limitations and restrictions

Currently support for this feature is limited to the Audiocodes gateway profile. Support for other gateway profiles will require an integration activity.

84.7 Interactions

Not applicable.

84.8 Glossary

Term	Description
SCTP	Stream Control Transmission Protocol
NAT	Network Address Translation

85: Functional Description(FN): A00009532

85.1 Feature name and Feature ID

Support host to host tunnels for all northbound OSS connections, A00009532

85.2 Description

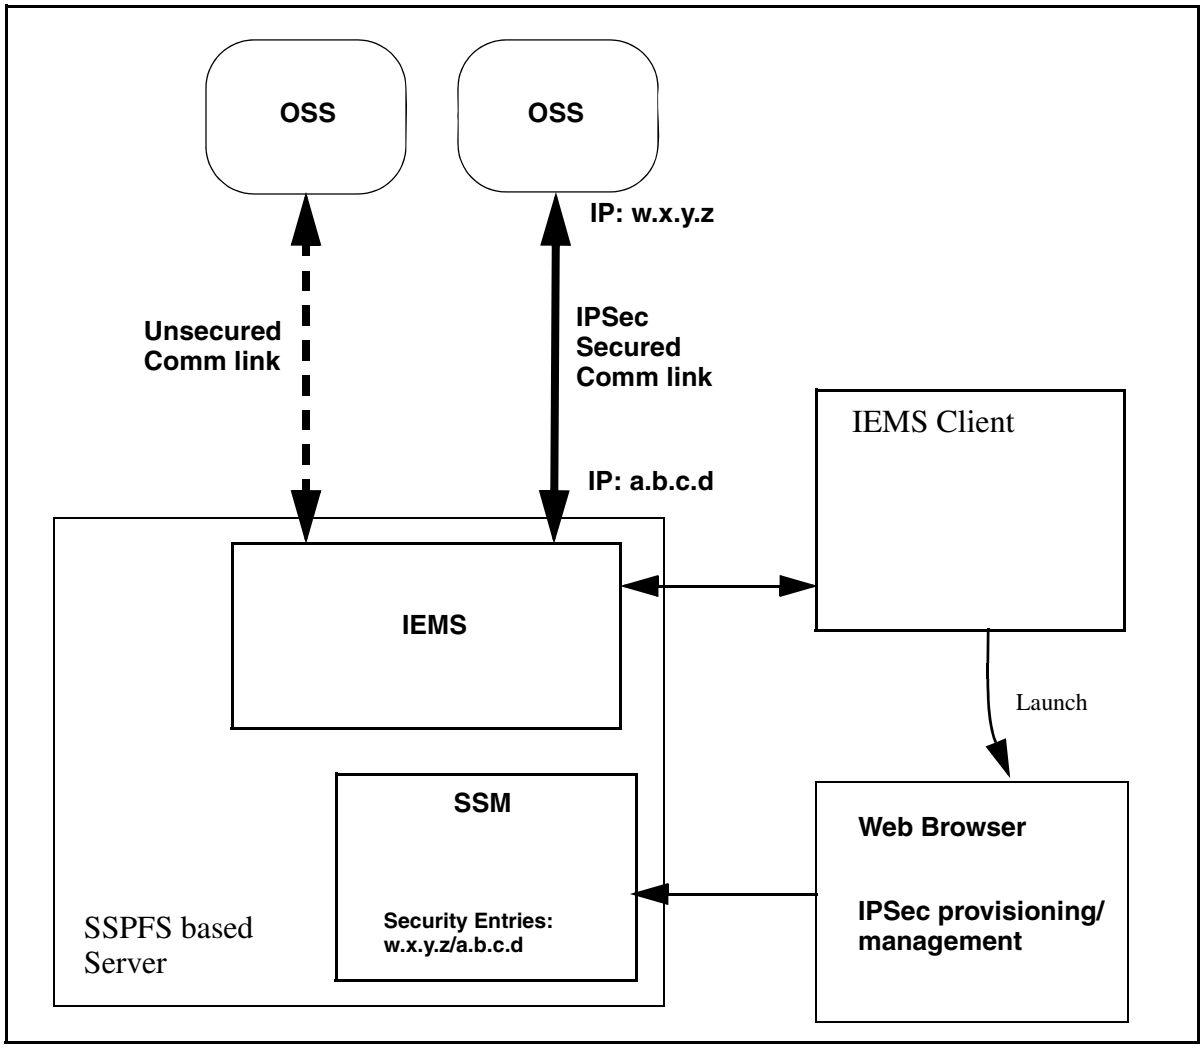
This activity is to test, verify and document host to host IPSec between SSPFS servers (namely IEMS, but not exlusively) and northbound OSSs. Securing this communications link will provide additional protection and encapsulation of OSS to IEMS traffic. The IPSec implementation will be in all other ways compliant with encryption key management and encryption protocol requirements in the Verizon agreement.

This activity will use the existing IPSec provisioning and management framework provided by SSPFS's Server Security Manager (SSM). SSM is currently used by the MG9K EM to secure communications channels with MG9K Network Elements.

All testing encompassing this feature will be based on the Solaris 9 software platform for SSPFS servers as well as OSS simulation. A Sun Netra 240 will be used for the SSPFS servers and a Sun Ultra 10 will be used for simulating the OSS.

The figure below gives a functional layout of the components involved with this feature. The main component of interest is the IEMS application running on a SSPFS based server. It provides input to the northbound OSS links. IEMS has a native GUI for craftsperson interaction. Another important component within SSPFS is the Server Security Manager (SSM). This component is used to provision and manage all IPSec related parameters for the SSPFS server and by extension all applications running on the server, such as IEMS. SSM is accessed using a standard web browser. The last component is the OSS which receives messaging output from IEMS. In this feature, for testing purposes, the OSS will be simulated.

Figure 1 Functional Layout



85.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies are introduced in the feature for the IEMS server.

85.4 Software Requirements or Dependencies

The latest SN09 IEMS software will be required for IPSec.

85.5 Limitations and restrictions

IEMS will not have direct control over the provisioning and management of IPSec security. This functionality is the domain of the Server Security Manager (SSM).

No new security parameters are being introduced in the Server Security Manager (SSM). This feature will utilize the existing functionality of SSM. That means Internet Key Exchange with preshared keys is the only supported mechanism for relaying encryption key information.

85.6 Interactions

Using IPSec to secure the northbound OSS interface will be invisible to the functionality and not have any impact to managing the traffic except for the additional step of provisioning the IPSec security parameters.

85.7 Glossary

Term	Description
IEMS	Integrated Element Manager System
SSM	Server Security Manager

86: Functional Description(FN): A00009550

86.1 Feature name and Feature ID

CBM-NPM Patching Convergence A00009550

86.2 Description

Prior to SN09, two software tools exist to administer software updates associated with SSPFS-based software; Core Billing Manager (CBM) Software Installation Manager (SIM) and Network Patch Manager (NPM).

Prior to SN09, SIM is used to maintain software updates associated with the CBM software in TDM, Wireless, and Succession configurations. In those configurations, SIM is also used to administer SSPFS-based patches on the CBM Solaris-based machines.

The intention of this feature is to integrate the CBM SIM functionality into NPM, and to support a single patch manager for the whole network to administer software updates for TDM/Wireless and Succession configurations. The NPM user interface is utilized as a central location for administering all software updates. For SSPFS based patches, the NPM is used in TDM/Wireless and Succession configurations for patch maintenance and administration. Also, for Core Element (CEM) based applications delivered with CBM, NPM is used for patch maintenance and administration.

Figure 2 SN09 TDM/Wireless Behavior

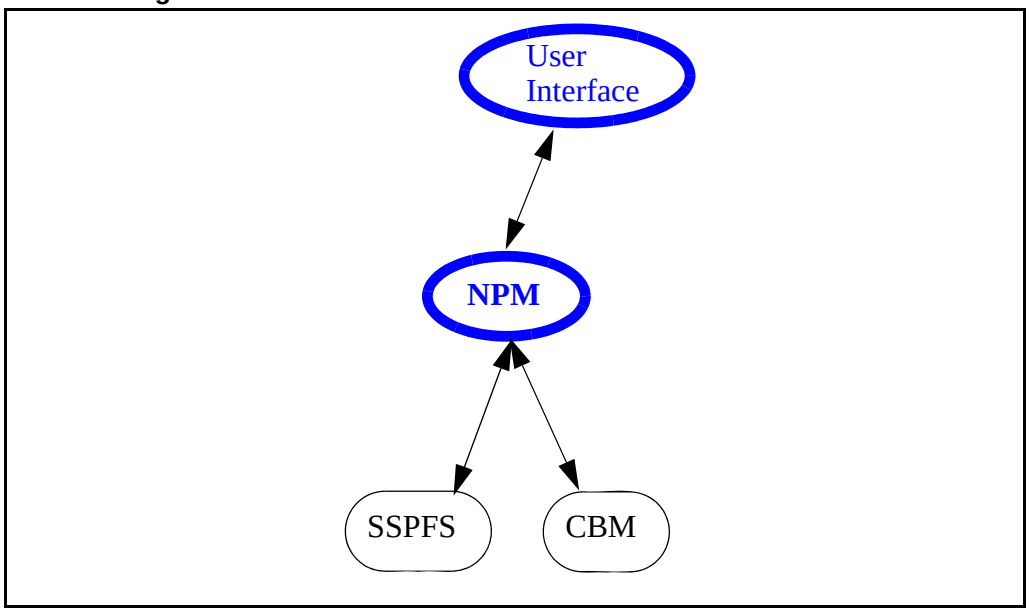


Figure 3 SN09 Succession Behavior

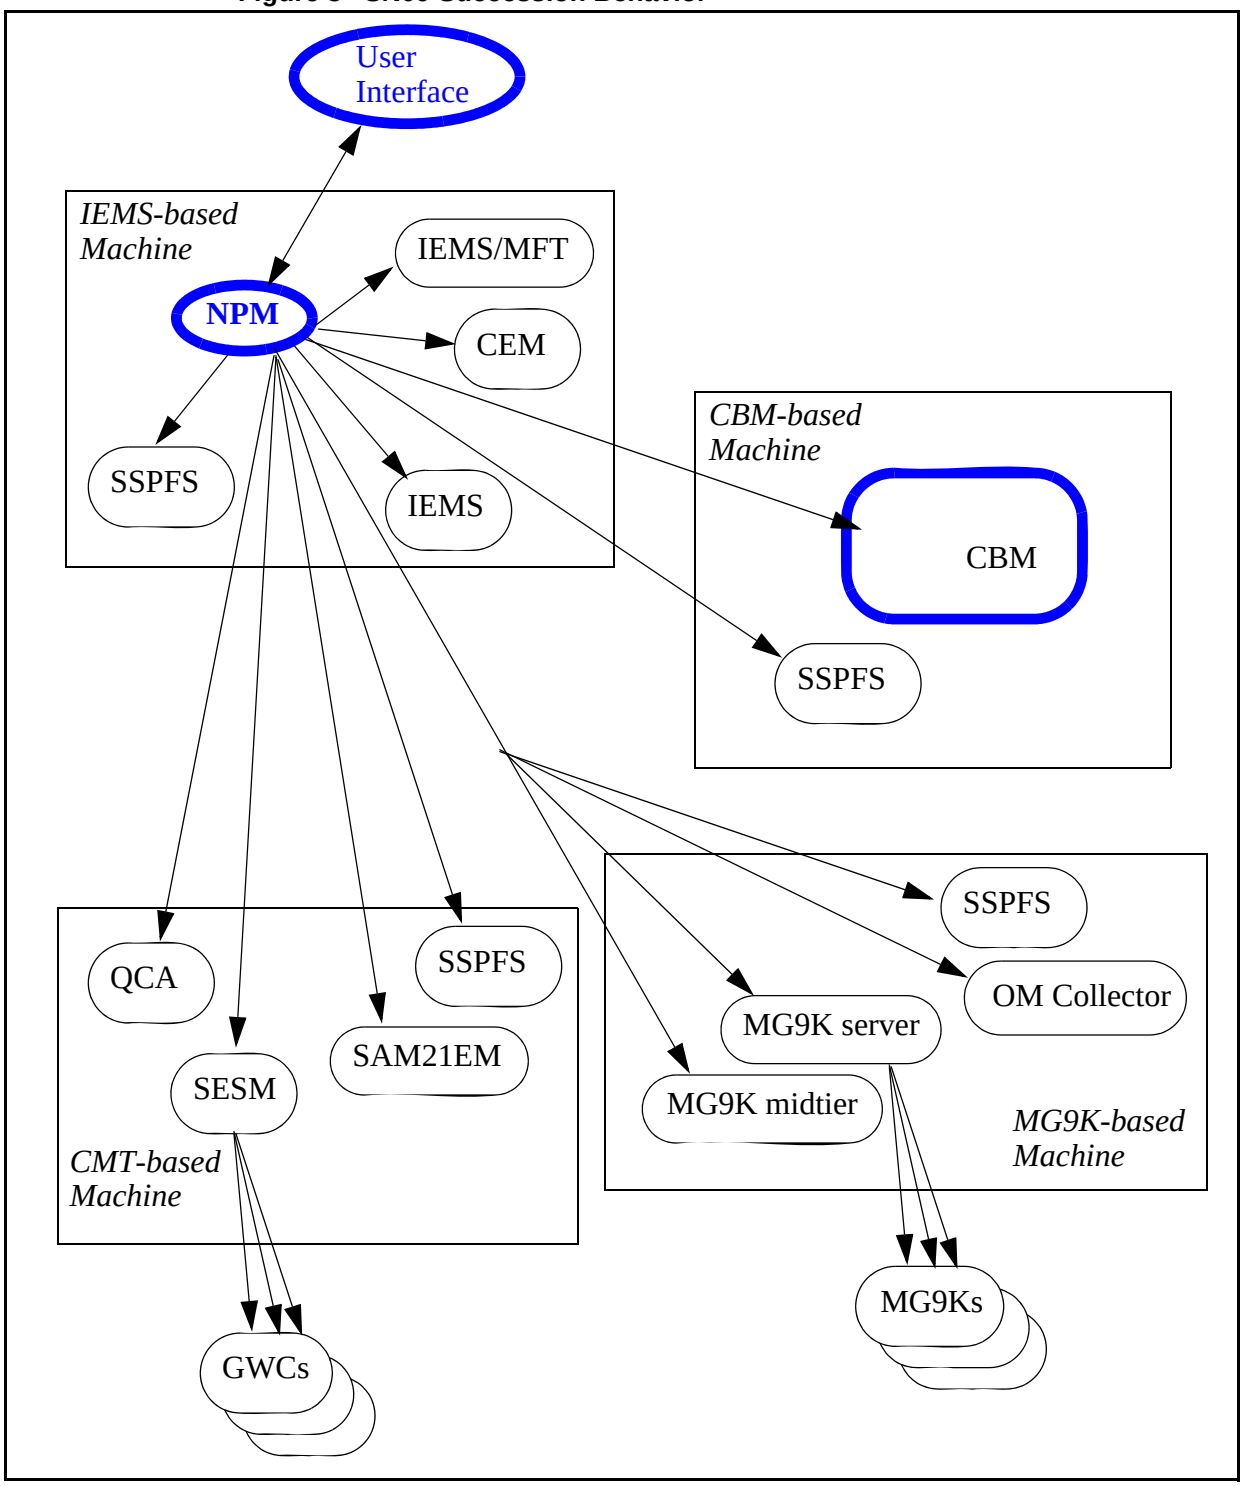

86.2.1 Cumulative Patching

CBM patches are cumulative. For CBM related applications, each patch

delivers the entire package content and subsequent patches contain the fixes that prior patches introduced. For CEM related packages, each patch delivers the file of the package that has changed and subsequent patches contain all previously changed files. Both approaches allows a customer to apply only the latest patch if desired since it will contain all of the fix content included in previous patches. CBM patches are delivered by RPS. There is only one Released patch at any given point in time for a particular package, unless it is the first patch for the package which can be at Verified or Released status. After a patch is Released for a package, all previous patches are set to Superseded in RPS and will no longer be delivered.

NPM is the patch management system to apply and remove CBM patches and perform maintenance patching activities on the CBM applications. All patching functionality available in NPM is available for CBM patching.

With this methodology of patching, if 3 patches have been released for a given package, and all 3 have been downloaded to a customer site, the customer can choose to physically apply patch 1, patch 2, and patch 3, or the customer can choose to apply patch 3 only. If only patch 3 is applied, this essentially results in having patch 1, patch 2, and patch 3 applied. If only patch 3 is applied, patch 1 and patch 2 cannot be removed individually. NPM will store a relationship attribute that indicates patch 3 is temporary (T) and patches 1 and 2 are bound (B). If only patch 3 is applied, when patch 3 is removed, patch 2 and patch 1 are also removed.

86.2.2 Multiple Devices

CBM registers with NPM as multiple patchable devices. A unique load name is associated with each device. The load name is used for patch calculation purposes. Patches are applied to and removed from a device. Devices are restarted to enable or disable patches. In a high availability (HA) or clustered environment, 2 instances of the device will appear; one instance for the active side and one instance for the inactive side. In a HA environment, customers have the option to apply patches on both sides individually, or request both sides be patched in one transaction.

An example CBM deviceid is CBM_BILLING.

86.2.3 Patching Maintenance

When the patchable CBM applications are installed, the NPM automatically becomes aware of them. CBM devices appear in reports and the device list of the NPM GUI or CLUI. The following functions that exist for other targets are now available for CBM devices.

- apply
- remove
- audit

- restart
- set/report creation
- plans/automation
- alarms

86.2.3.1 CBM Patch Application and Removal

Like existing OAM Java-based applications such as SESM, SAM21EM, or IEMS components, the CBM requires 2 steps for application and 2 steps for removal of patches.

application

- apply command from the NPM GUI or CLUI (sets patch to applied/ disabled and stages patch for actual patch application)
- restart command from the NPM GUI or CLUI on CBM device (sets patch to applied/enabled after restarting the device)

removal

- remove command from the NPM GUI or CLUI (sets patch to removed/ enabled and prepares patch for actual patch removal)
- restart command from the NPM GUI or CLUI on CBM devices to disable the patch (sets patch to removed/disabled after restarting the device)

When CBM is running in a clustered configuration, the 2 step application and removal of patches is necessary on the active side of the SSPFS-based machine, and only for those devices which have running applications on the inactive side. A restart from the NPM GUI or CLUI of a CBM device is required to enable or disable patches only for those devices which have running applications. When a patch is applied to or removed from CBM device which has no running applications, the patch is automatically enabled or disabled.

The apply and restart operations from the NPM GUI and CLUI can be automatically scheduled via NPM plans (autoapply and autorestart).

NPM will not automatically reboot a machine for a patch that has a reboot required.

86.2.4 Patchid

The patchid format for CBM patches can have up to 32 alpha-numeric characters. An example CBM patchid is NTBASE220203-01. The patchid of the second version of that patch is NTBASE220203-02.

86.2.5 Patch File Format Modifications

The patch file format is modified with this feature. The following additions and changes have been made.

- A new **H** record is introduced to track patches that cannot be applied when the given patch is applied. This would happen in the case of a patch that had previously depended on a patch which became obsolete. Once a dependency is obsolete, any new patches cannot depend on that. This new record is stored in the ADM section of the patch file. Zero to many of these records can exist.

  H ANTI_PREREQ <patchid> where patchid is the name of the patch that cannot be applied when the given patch is being applied.

86.2.5.1 Patch Delivery to Customers

RPS is used to deliver CBM patches to customers. NPM has a Patch File Receipt System (PFRS) setup that allows the customer to configure where to have patches delivered for NPM to retrieve, and where to deliver an inform report for RPS to use for patch calculation purposes. RPS will deliver CBM patches based on a calculation of the load name associated with a patch and the load name associated with the device on site. Information on PFRS setup can be found in the online NPM GUI or CLUI help.

RPS delivers only the latest version of a patch for a given software package. Once a new version of a patch is released, all previous versions are Superseded and are no longer delivered. The customer needs to only apply the latest version of a patch since it includes in it all previous software changes.

86.2.5.2 Online Help

NPM provides the user online help via the GUI or CLUI. A CLUI help document is also available in the NpmCluiHelp.PDF document on the NPM server machine at /opt/nortel/NTnpm/documents.

86.3 Hardware Requirements or Dependencies

A windows based PC machine is required to use the NPM GUI.

86.4 Software Requirements or Dependencies

The SN09 CBM load is required to interact with NPM.

86.5 Limitations and restrictions

86.5.1 Patch Dependencies and Maintenance Releases

In SN09, patch dependencies are permitted between patches applicable to different devices. A CBM patch can have a dependency on an SSPFS patch. If an SSPFS maintenance release (MR) is created and contains a dependent SSPFS patch, the CBM software that requires the now built in SSPFS patch will also have to build a new MR on top of the SSPFS MR. If this is not done,

some other type of software delivery strategy will need to be implemented for the CBM load that contains the patch with a dependency.

86.5.2 Patch Dependencies and Obsolete Patches

A CBM patch can have a dependency on a patch in the SSPFS device. If a patch dependency is created between a CBM patch and an SSPFS patch, and the SSPFS patch becomes obsolete, all CBM patches that depend on the obsolete SSPFS patch must be removed from customer sites. Once an SSPFS replacement patch is downloaded and applied, a new CBM patch is created that depends on the replacement patch, and then delivered to customers. If obsoleting an SSPFS patch is determined to be too disruptive, a new SSPFS patch should be written on top of the bad SSPFS patch and delivered to the customer.

86.6 Interactions

None

87: Functional Description (FN) A00009576

87.1 Feature name and Feature ID

SN09FF H.323 RASLess Provisioning - A00009576

87.2 Description

This feature delivers the ability for a craftperson to explicitly provision the CS2K with the optional "RAS-less" functionality on a H.323 gateway/ gatekeeper basis. The RAS-less capability is configured during gateway association via the CS2K Management Tools server.

H.225 defines RAS (Registration, Admission and Status) messages and procedures for controlling access to the network. These messages allow H.323 endpoints to discover and register with a H.323 gatekeeper, to provide information about their capabilities and to request the allocation of appropriate amounts of bandwidth. For some applications, H225/H245 signaling should be used between the CS2K and another entity (e.g. softswitch, gatekeeper, or gateway) for setting up calls, but with no RAS messages. This mode of operation is deemed "RAS-less".

The optional RAS-less capability can be provisioned via the GUI or OSSGate XML interface of the CS2K Management Tools server during gateway association. Only H.323 gateways/gatekeepers can be configured with the RAS-less option.

87.2.1 CS2K Management Tools GUI changes

The associate gateway operation has been updated with the ability to configure the optional RAS-less capability. The RASLess option is displayed as part of the GWC Provisioning Panel of the CMT (CS2K Management Tools) GUI. The "Details" button of the Gateway tab has been updated to display the RASLess option configuration setting.

Once the associate media gateway operation is invoked, the corresponding associate media gateway dialog is launched. To configure the RAS-less functionality, a craftperson must choose a H.323 gateway profile from the "Gateway profile name" pull down menu of the associate media gateway dialog box.

If a H.323 gateway profile is chosen, specific H.323 configuration data options are presented. A new optional gateway data application panel has been added to the associate gateway dialog box. The optional "RAS-less" data is presented as part of the new optional gateway data choices. A craftperson can enable the RAS-less capability by setting the option to "true". The default value is "false".

Once all the required data is entered, the “OK” button of the associate media gateway dialog box will be enabled. By clicking on the “OK” button, the GWC EM will process the operation and generate the required SNMP messages. The SNMP messages are sent to the respective GWC. The craftperson will receive a successful or failure response from the GWC EM upon completion of the operation.

The “Details” button of the Gateway tab of the GUI will display the new optional data if supported by the specific gateway profile. A craftperson can click on the Details button to launch a gateway’s Details dialog box. The optional gateway data will be displayed for the respective gateway. The RASLess option is listed in the dialog box if the selected gateway is H.323. If there isn’t any gateway application data defined for the selected gateway, a dialog box will be launched indicating the respective gateway profile does not have any optional data defined.

The Details button is also used to display the associated “root middleboxes” of a respective gateway. Currently, H.323 gateways do not support root middleboxes.

Note: *All current H.323 gateway profiles support the new optional RASLess configuration except for the H323_PROXY gateway profile.*

87.2.2 OSSGate XML interface changes

The assocMG and queryMG operations of the OSSGate interface have been modified to support the optional RAS-less configuration data. The optional RAS-less data is only applicable to H.323 gateways/gatekeepers.

XML Associate MG changes

The optional RAS-less data has been added to the assocMG operation and can be configured against a H.323 gateway/gatekeeper.

To configure a “RASLess” H.323 gateway/gatekeeper, a valid assocMG XML command must include the optional RAS-less data.

assocMG - specifies the provisioning method. It has two attributes: USN (Unique Sequence Number) and version. The USN is used by an OSS to map requests with responses. The USN value specified in the request is returned in the response. The version attribute specifies the version of the method being used.

Parameters - specifies that the following elements are parameters for the method. Included in the parameters are:

• **mgUIName** - delimits MG name value.

• **mgProfileName** - delimits the MG profile name value to be applied to the MG.

• **mgIpAddr** - delimits the MG IP address value.

The new parameter is:

• *gwAppDataList - delimits the new optional data which includes **RASLess.***

XML Query MG changes

The optional RAS-less data has been added to the queryMG operation ***response*** and will only be returned when a H.323 gateway/gatekeeper is queried. The queryMG XML command has not been modified.

queryMG - specifies the provisioning method. It has two attributes: USN and version. The USN is used by an OSS to map requests with responses. The USN value specified in the request is returned in the response. The version attribute specifies the version of the method being used.

Parameters - specifies that the following elements are parameters for the method.

mgUIName - delimits MG name value. When this parameter element is specified the attributes of the MG specified are returned.

If a H.323 gateway/gatekeeper is queried, the RAS-less configuration will be returned via the optional device data parameter.

The optcn component of the A00009576 book contains GUI and XML examples detailing the new RASLess option for H.323 gateways/ gatekeepers. The OSS User's Guide details the OSSGate interface.

87.3 Hardware Requirements or Dependencies

There are no hardware requirements or dependencies for the CS2K H.323 RAS-less optional capability.

87.4 Software Requirements or Dependencies

This feature is being delivered as part of the Succession release SN09FF.

87.5 Limitations and Restrictions

• The optional RAS-less feature can only be provisioned against H.323 gateways/gatekeepers on the CS2K.
• The gateway profile "H323_PROXY" does not support the RAS-less functionality.
• The optional RAS-less feature is not supported with a NAT configuration of N:1. The N:1 NAT configuration is when multiple gateways behind a NAT

share the same “NAT’d” IP address and the gateways are uniquely identified by the port value.
• The provisioned protocol port value of the H.323 gateway/gatekeeper on the H.323 GWC (via the CMT GUI or XML interface) must be set to the CS (call signaling) port value of the gateway for RAS-less mode. (i.e. If the H.323 gateway is not behind a NAT and the call signaling port value is set to 1720 on the gateway, the gateway’s provisioned protocol port value on the GWC must be set to 1720).
• A RAS-less H.323 gateway that is behind a NAT with a 1:1 configuration (one private IP mapped to one public IP to the H.323 GWC), must have the provisioned protocol port value on the GWC set to a non-zero port value. The non-zero port value on the GWC must be mapped via the NAT to the gateway’s call signaling port value.

87.6 Interactions

This activity enables a craftperson to explicitly provision the RAS-less functionality against a H.323 gateway/gatekeeper on the CS2K. The associate gateway operation processed on the CS2K Management Tools server is updated with the ability accept the optional data via the GUI or XML interface.

87.7 Glossary

88: Functional Description(FN): A00009610

88.1 Feature name and Feature ID

A00009610: IEMS Calix Integration

88.2 Introduction

IEMS serves as an integrated platform for managing various devices. One among those devices is Calix C7 Ultra Broadband Digital Loop Carrier. This document lists the changes that are required in IEMS in order to manage a Calix device.

The Calix C7 implements three network management interfaces: TL1, GUI and SNMP. IEMS will use the SNMP interface for inventory and fault management. For configuration the TL1 and GUI would be used in the form of launches.

88.2.1 2. Acronyms Used

IEMS – Integrated Element Management System

GUI – Graphical User Interface

SNMP – Standard Network Management Protocol

TL1 – Transaction Language 1

88.3 IEMS Changes

88.3.1 3.1 C7 Provisioning

The C7 Network can be provisioned in IEMS as a Network Element. The C7 Network can be added from the existing Tools-->Add-->EMS / NE menu. The IP Address field represents the IP of the Calix Proxy Agent. 'Type' should be selected as NE. In the 'Device Type' a new entry, named 'C7 Network', will be added. Two new text fields will be added for the GUI Launch IP Address and TL1 IP Address. The SNMP details can be filled up on the next screen. This would be the same as the existing Fault Interface screen.

In order to discover the C7 network the calixDeviceTable in the calixProxyAgentMib is queried. This table will be queried for the following conditions

1 When a C7 Network is provisioned in IEMS

2 When the IEMS server restarts

3 When there is a communication regained after a communication loss to the C7 device

4 User issues a manual Re-Synchronize Inventory from the IEMS client

5 Trap or an alarm for an unmanaged shelf is received in IEMS

The following table lists some of the managed object properties for these objects

Property Name	*C7 Network*	*C7 Node*	*C7 Shelf*
Name	<HostName of provisioned network>-C7	<C7NetworkName>_node<nodenumber>	<C7NodeName>_shelf<shelfNumber>
DisplayName	As provided by the user	<C7NetworkDisplayName>_<sysName using the networkIP and shelf port>	<C7NetworkDisplayName>_N1-1
Type	NE-C7	C7Node	C7Shelf

The C7Node and C7Shelf are modelled as CalixObject in IEMS. A separate table named CalixObject will be created in IEMS. We will be storing the following details pertaining to the C7Node and C7 Shelf.

Column Name	*Description*
NetworkName	Name of the C7Network to which this node belongs
DeviceName	This is the value as obtained from the calixDeviceName column of the calixProxyAgentMib. For a node this will be in the format N1,N2 etc and for a shelf this will be N1-1,N2-1 etc.
NodeNumber	This represents the node number
ShelfNumber	This represents the shelf number
Name	This is the name of node or shelf

The parent-child relationship is maintained between the C7 Network-Node-Shelf objects. While adding the C7 objects the C7Network is set as the parent for C7Node and the C7Node is set as the parent for C7Shelf.

88.4 Topology

The C7 Network would be listed under the Network Elements node of the topology tree. As there can be multiple C7 networks, each network is represented as a separate tree node. The topology tree for the Calix device is as below

Network Elements
C7 Network
- Net1
- N1

- N2

where ,
Net1 – is the displayName of the C7 Network as given while provisioning the network.
N1, N2 – represent the nodes of the provisioned network

The C7 Network, Net1, N1 and N2 all bring up a map when clicked.

On selecting the C7 Network tree node all the provisioned networks are listed in the right hand panel. These networks would also appear on selecting the Network Elements tree node.

On selecting the Net1 tree node all the nodes for that network are shown in the right hand panel.
On selecting the N1 and N2 tree node the corresponding shelves under that node are shown in the right hand panel.

89: Functional Description(FN): A00009611

89.1 Feature name and Feature ID

A00009611 IEMs Keymile Integration

89.2 Introduction

The UMUX Multi-service Access platform comprises a range of modular multi-service network elements (UMUX 1500/1200/900) and can be configured/managed by Keymile's UMUX Network Element Manager (UNEM).

IEMS serves as an integrated platform for managing various devices. The Keymile devices UNEM/ UMUX NEs Multi-service Access platform will also be managed by IEMS. This document lists the changes that are required in IEMS in order to manage a UMUX device.

The UMUX implements two network management interfaces: GUI and SNMP. IEMS will use the SNMP interface for inventory and fault management. GUI would be used in the form of launches.

89.3 Acronyms used

IEMS – Integrated Element Management System
GUI – Graphical User Interface
SNMP – Simple Network Management Protocol

89.4 IEMS Changes

89.4.1 UNEM Provisioning

The UNEM can be provisioned in IEMS as an Element Manager. The UNEM can be added from the existing Tools-->Add-->EMS / NE menu. The IPAddress field represents the IP of the UNEM . 'Type' should be selected as EMS. In the 'Device Type' a new entry, named 'UNEM Mgr', will be added. The SNMP details can be filled up on the next screen. This would be the same as the existing Fault Interface screen for other snmp devices.

89.4.2 Topology

The UNEM would be listed under the Element Managers node of the topology tree. As there can be multiple UNEM networks, each network is represented as a separate tree node. The topology tree for the UNEM device is as below

89.4.2.1 Element Mangers

- EMS-UNEM-Mgr (displayName of the UNEM)

- EMS-UNEM-Mgr (displayName of the UNEM)

89.4.2.2 Network elements

The UMUX Network Elements (UMUX 900/UMUX1200 & UMUX1500) will be auto discovered and added to the inventory. These network Elements will be represented in the tree as below

Network Elements
|-UMUX-1200
|-UMUX-1200-(displayName of the UNEM)
|-UMUX-1200-(displayName of the UNEM)
|-UMUX-900
|-UMUX-900-(displayName of the UNEM)
|-UMUX-900-(displayName of the UNEM)
|-UMUX-1500
|-UMUX-1500-(displayName of the UNEM)
|-UMUX-1500-(displayName of the UNEM)

The UMUX -1200 map will contain all the nodes of NE type (UMUX-1200) of a given UNEM Mgr which will be indicated using the displayName of the UNEM Mgr.

The UMUX -900 map will contain all the nodes of NE type (UMUX-900) of a given UNEM Mgr which will be indicated using the displayName of the UNEM Mgr.

The UMUX -1500 map will contain all the nodes of NE type (UMUX-1500) of a given UNEM Mgr which will be indicated using the displayName of the UNEM Mgr.

The neTable with the below mentioned information will be used to populate the Inventory table for the UMUX devices.

neFamily,neIndex,neName,neUNEMAdress,neType,

neFamily + neIndex -- will be the unique name of the UMUX devices

neName -- will be mapped to the displayName

neType – will represent the type of the device (family)

89.4.2.3 Inventory Synchronization

The Inventory Synchronization can happen on the below mentioned conditions:

- While IEMS is restarted
- When ever a trap loss is detected, IEMS will automatically invoke reSync of Inventory.

- Manually invoking the ReSync Inventory

89.4.3 Topology Trap handling

The below mentioned topology traps will be handled:

- neAddedTrap -- IEMS checks for the type of the device and if the type is either
- (neType-11, neType-8, neType-7) the same will be added to the inventory table. All other traps will be considered as traps from unknown devices and the traps will anyway be forwarded to the north bound as INFO events.
- neDeletedTrap – IEMS checks for the corresponding entry in the inventory table and deletes the device. For all the traps originating from the unknown device and the trap will be forwarded as an INFo event to north bound.
- neNameChangeTrap – IEMS checks for the corresponding entry in the inventory table and changes the neName (displayName) of the device. For all the traps originating from the unknown device and the trap will be forwarded as an INFo event to north bound.
- neOpStatModifiedTrap – IEMS will just forward the trap to the NorthBound as INFO events and will not store them in the Alarms table.
- nePollStatModifiedTrap - IEMS will just forward the trap to the NorthBound as INFO events and will not store them in the Alarms table.
- CardAddedTrap – IEMS will forward the trap to the NorthBound as INFO events and will not store them in the Alarms Table.
- CardDeletedTrap – IEMS will forward the trap to the NorthBound as INFO events and will not store them in the Alarms Table.

All the system traps (alarmNEFamily – 4 & alarmNE – 9999) will be mapped to the UNEM

90: Functional Description(FN): A00009612

90.1 Feature name and Feature ID

A00009612 Restricted Shell Access

90.2 Description

"Restricted Access Shell" in SN09 provides a new default shell for interactive users. This shell (called rash), unlike sh or ksh or bash will limit the available suite of commands. Additionally a user will not be able to alter their path and will therefore be restricted to only those commands authorized. Additional commands can be registered to be available to rash via servman.

Two of the commands used by IEMS that fall into this restricted access morass are telnet and ssh. As a result, the proxied "Command Line" context menu item used from the IEMS map will no longer work. The invocation of the telnet or ssh command will elicit a "command not found" message when invoked from rash.

In a proxied command line scenario the IEMS client uses SSH (Mindterm) to establish and login to a shell session on the IEMS server. From there the ssh or telnet command is issued and another SSH or telnet session is established with the southbound NE or EMS. The shell session on the IEMS server will use the restricted access shell provided by A00009310 and hence will be prohibited from invoking either the telnet or ssh commands.

This component will rectify this and insure that the proxied command line in SN09 will retain functionality equivalent to that found in SN08. A script (IEMSProxyCommandLine) will be created for the telnet and ssh commands on the IEMS server that will,

1 Perform a check to insure that the logged in user is authorized to access the target device. The check will use the same logic and code provided by IEMS. The users membership in the 30 Succession groups and any policy rules defined in the IEMS server will dictate authorization.

2 Create an audit log for successful authorization or a security log for unsuccessful authorization.

3 invoke the real ssh and telnet command to establish a remote session with the target device.

The script will support all options and parameters of both ssh and telnet and will not alter either the performance or appearance.

Additionally a login to the IEMS server will place the user into a restricted access shell with a home directory as defined in users profile in the security

server. A script run from pam during login will create the user's home directory and copy skeleton profiles to it.

90.3 Hardware Requirements or Dependencies

Not applicable

90.4 Software Requirements or Dependencies

This is required due to implementation of A00009310.

90.5 Limitations and restrictions

None

90.6 Interactions

90.6.1 IEMSProxyCommandLine script

The IEMSProxyCommandLine script will support all options and parameters of both ssh and telnet and will not alter either the performance or appearance. It does introduce any new options or arguments.

90.6.2 Home Directory and Skeleton Profiles

The home directory of the user will be created. Additionally, two sub-directories of "data" and ".ssh" will be created. The former is read-write and available at the discretion of the user. The latter is used to store public encryption keys used by ssh. Skeleton profiles, shipped with SSPFS and found in /etc/skel.rash, will be copied into the home directory.

90.6.3 Logs

An Audit Log Entry would be found for a successful authorized access.

Feb 22 11:39:37 comp5iems IEMS: IEMS class_security.ver01 STAT=SUCCESS SRC.USR=gumby EVNT.TYPE =/usr/bin/ssh to 47.142.106.26, device type EMS-CS2K-Mgr

A Security Log Entry would be found for an unsuccessful, unauthorized access. Note that for authorization to succeed both the userid and the target host ipaddress must be known to the IEMS server. If either is unknown then the authorization will fail.

Feb 22 11:39:37 comp5iems IEMS: IEMS class_security.ver01 STAT=FAILURE SRC.USR=gumby EVNT.TYPE =/usr/bin/ssh to 2.3.4.5, device type GWC

90.7 Glossary

91: Functional Description(FN): A00009614

91.1 Feature name and Feature ID

A00009614: Tamper-proof Key Storage and Event Generation

91.2 Description

This document will cover work for IEMS and SSPFS. This document does not address key material owned and controlled by the Security Server.

Key material is defined to be anything that is used to authenticate a user or machine to another machine. This includes X.509 certificates, cryptographic keys, userids, passwords, and SNMP community strings.

This feature will create cron job that will run once a day to:

- Generate a minor alarm for the expiration or warning expiration of certificates.
- Generate an alarm for the expiration of system or local accounts and passwords. A system account is defined to be any account used for program to program or machine to machine authentication.
- Generate an alarm warning that an account or password is about to expire.

Scripts that manage key material will also generate a security log for any attempt to add, delete, or modify key material--whether valid or under attack.

Alarm and log details can be found in the Fault Management (FM) section that follows.

91.3 Hardware Requirements or Dependencies

Not applicable

91.4 Software Requirements or Dependencies

This feature uses:

- the cron facility of unix to run a program periodically.
- the perl interpreter

91.5 Limitations and restrictions

This feature will not cover central user accounts managed by IEMS or certificates automatically generated by IEMS Security Server during installation.

91.6 Interactions

91.7 Glossary

Term	Description

92: Functional Description(FN): A00009616

92.1 Feature name and Feature ID

A00009616: IEMS Backward Compatibility and Upgrade

92.2 Introduction

IEMS serves as an integrated platform for managing various devices. This module is for providing Backward Compatibility in IEMS so that all the SN09 device versions and the previous device versions (n –2) are supported in IEMS. This document lists the devices and the changes required for the devices. The document also covers client interoperability and Upgrades.

92.3 Backward Compatibility

92.3.1 Device Version Changes:

In SN08 when an EM/Platform/application is added a drop down to choose the version is provided in most cases. The SN08 drop down box contains the following versions namely 6.2, 7.0 and 8.0. The SN09 version of IEMS will not support the 6.2 version of devices. So the SN09 drop down box will not contain the 6.2 version and it will contain 07, 08 and 09 versions.

SAM21-Mgr is an exception here. The user can provision the version as NONE for SAM21-Mgr. IEMS will auto-populate the version for SAM21-Mgr for the first time when it gets discovered. IEMS will query the versioned interface and populate the device version in the IEMS database of its own.

92.3.2 IEMS Version Changes:

In SN09, all the GUI titles/About boxes will show 09 as the current IEMS Version. The version of the package as output by the pkginfo command will show 09 as the current IEMS Version e.g., VERSION: IEMS_8_03_0 ==> IEMS_090_0503.

The output of pkginfo command:

```
iems-sf2:/> pkginfo -l IEMS
 PKGINST:IEMS
      NAME:Nortel Networks Integrated EMS
        CATEGORY:application
       ARCH:sparc
VERSION:IEMS_090_0503
```

```
BASEDIR:/opt/nortel/iems/current
VENDOR:Nortel Networks
 PSTAMP:cmsol2-build20050221080539
           INSTDATE:Jan 23 2005 08:14
 STATUS:completely installed
      FILES:3908 installed pathnames
             197 directories
               69 executables
         192995 blocks used (approx)
```

92.3.3 CBM Security Integration

SSO is being introduced on CBM in SN09. CBM will point back to IEMS server for authentication. Hence the launch of SSPFS with CBM needs to be performed via SSO in IEMS SN09.

To address the above requirement the following changes needs to be performed in IEMS.

1. Radius configuration of the CS2K Core Manager needs to happen during provisioning.
2. The launch of command line needs to be SSO enabled. Launch needs to be consistent with SDM.
3. Upgrade of CBM from version 07 to 09 should give options to include any new attributes.
4. Upgrade of CBM from version 08 to 09 should give options to include any new attributes.
5. SN09 IEMS should be backward compatible with older CBM versions.

92.3.4 MDM Integration in SSPFS

The following changes needs to be performed in IEMS for MDM moving to SSPFS platform.

1. When provisioning an MDM in IEMS an option needs to be provided for the user to select if the platform is SSPFS or not.
2. If user chooses SSPFS:
   - IEMS will not auto discover the platform in IEMS topology as we do in SN08. Platform Alarms will correlate to the MDM EM.
   - User should be able to associate an SSPFS platform if it has already been added.

— User will have to manually add the SSPFS platform.

3. If user selects no-SSPFS, existing behavior as in SN08.

92.4 Supported OS and browsers

The SN09 version of IEMS Client will be supported in the following Operating Systems and web browsers.

92.4.1 PC Platform

	Win 2000, SP4	Win XP, SP2
IE 6 SP1	YES	YES
Netscape 6.2+	YES	YES

92.4.2 Sun Platform

	Solaris 8 (2.8, 5.8)	Solaris 9 (2.9, 5.9)
Mozilla (1.4 +)	YES	YES
Netscape 6.2+	YES	YES

92.4.3 Collection Job Changes

In SN08, when defining a collection job by default the discovered devices are added into the job. The list of discovered device IPs is listed in the "Exclude Device List". If a user want to exclude some device, he needs to uncheck (x) the device, which listed in the "Exclude Device List".

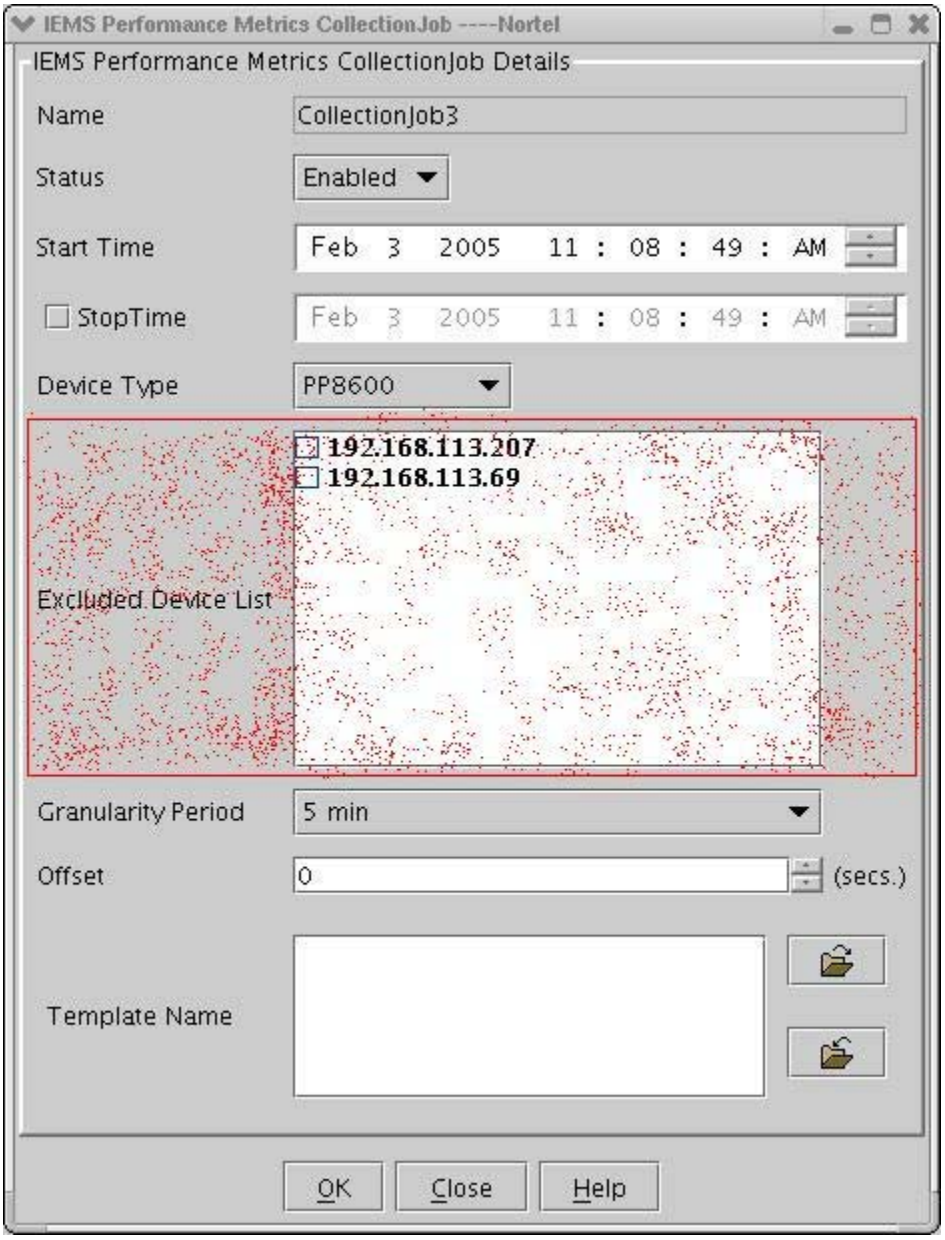

Figure 1 SN08: Collection Job Configuration Screen

But in SN09, when defining a collection job by default the discovered devices will not be added into the job. When defining a collection job user needs to add the devices (by enabling the check box) into the Collection Job i.e., the "Exclude Device List" is changed to "Include Device List".

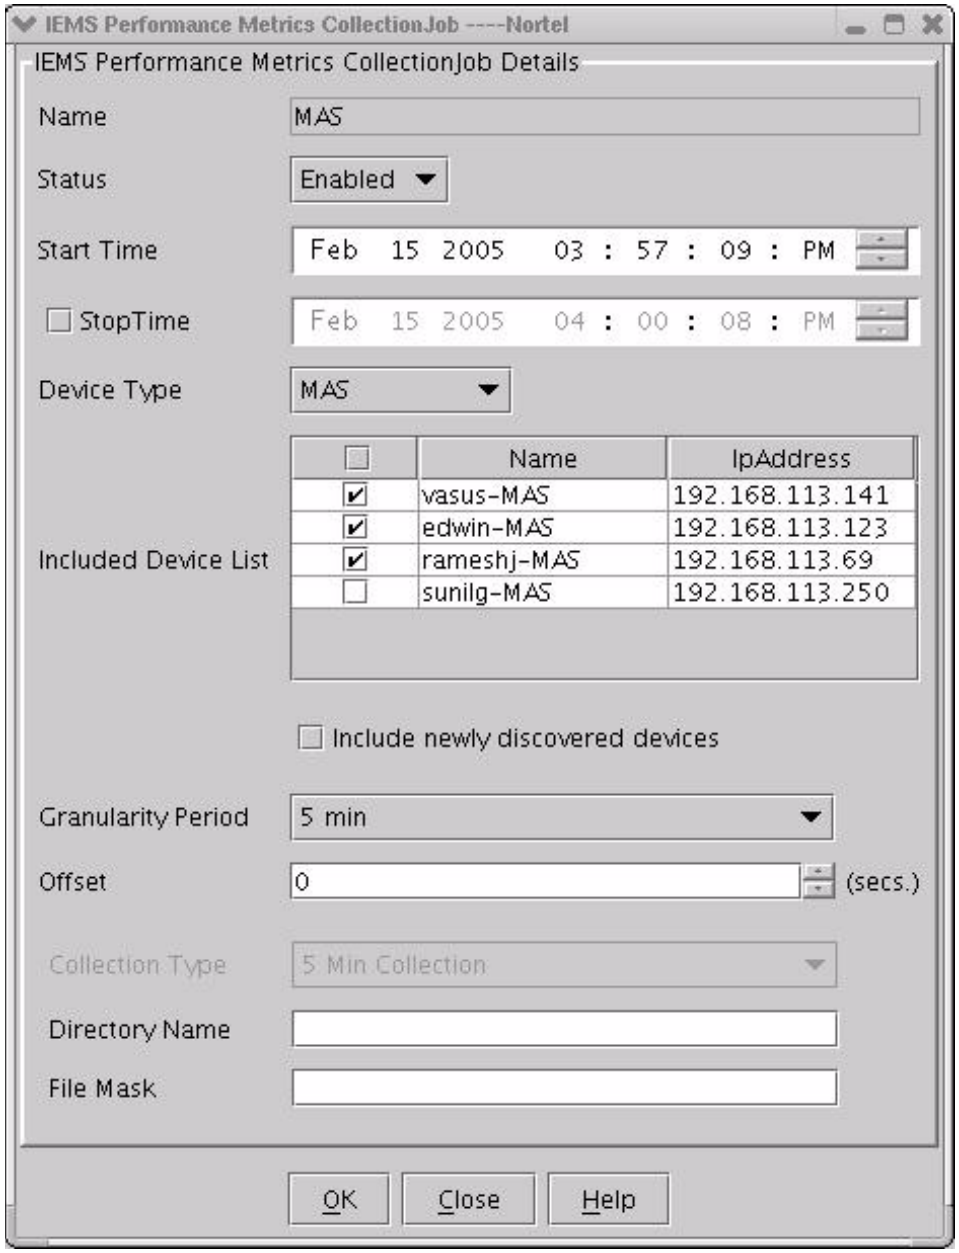

Figure 2 SN09: Collection Job Configuration Screen

The device list will be displayed in a table structure. The table has 3 columns with following headers,

- (Just a check box)
- Name
- IP Address

The first column header and all the first column cells will contain a check box. All the check boxes will be unchecked by default. If a user check /uncheck the first column header then, it will automatically check /uncheck all the devices in the table. The discovered devices name and IP Address will be displayed in the second and third column of the table respectively. The data collection will be performed only selected (checked) devices.

The checkbox “Include newly discovered devices” will be unchecked by default.
If this checkbox is checked, the data collection will be performed for the newly discovered devices.

For the already existing jobs in SN07/SN08 when migrated to SN09, the excluded device list will be displayed as unchecked in the new collection job GUI. This will be taken care during data migration from SN07/SN08 to SN09.

92.5 Upgrades

92.5.1 Upgrade Path

This section covers the functional description for IEMS (IEMS/MFT/CEM) upgrade in the following scenarios:

- SN07 to SN09 Upgrade
- SN08 to SN09 Upgrade
- SN09 to SN09 Upgrade
- SN09 to SN07 Rollback
- SN09 to SN08 Rollback
- SN09 to SN09 Rollback

92.5.2 Limitations & Restrictions:

- Downgrade of IEMS is not within the scope. i.e. Once the upgrade/ migration is completed fully and the SN09 version of IEMS is running, the downgrade of SN09 data to be compatible with SN08 / SN07 is not supported.
- Rollback will involve only Backup & Restore and hence it will resume activity at the last “save” point. Separate Rollback is not done for IEMS.
- IEMS server will not be running while upgrade procedure is invoked. HA upgrades will occur on inactive unit.
- IEMS does not support a “no outage” upgrade. The outage window is mainly determined by the failover time needed for SSPFS HA systems. In case of Simplex it will be the time required for completing the IEMS upgrade procedure and starting IEMS.

- IEMS upgrades do not support migration. This includes:
- Migration from a standalone IEMS to a co-resident IEMS (IEMS + CMT)
- Migration from a co-resident IEMS to a standalone IEMS
- If the Upgrade/Data migration fails, the only recovery technique is to restore via a file system backup.
- IEMS does not support a hardware migration.

In SN09 release, Integrated EMS will reside on the following platforms:

- Standalone (Integrated EMS on SSPFS)
  - On single N240 (simplex) 4G - NTRX51LC
  - On dual N240 (HA) 4G - NTRX51LC
- Co-Residency (CS2M & Integrated EMS on SSPFS)
  - On single N240 (simplex) 4G - NTRX51LC
  - On dual N240 (HA) 4G - NTRX51LC
  - On single T1400 (simplex) 4GB Only – NTRX51KW - Requires a T1400 upgrade procedure - for existing T1400customers only. No new T1400 installs are planned.

92.5.3 Hardware upgrade paths

The Integrated EMS will require the following upgrade plans

- T1400 in OAME cabinet standalone -> T1400 co-resident in OAME cabinet
- N240 simplex with CS2M in COAM cabinet -> N240 simplex co-resident in COAM cabinet
- N240 simplex in COAM cabinet -> N240 co-resident HA in COAM Fame
- OAME cabinet to COAM cabinet

92.5.4 Upgrade Procedure:

92.5.5 IEMS Upgrade pre-check:

A standalone script file (IEMSUpgradePreCheck.sh) will be present under <IEMS home>/bin directory.

The purpose of the pre-check script is so that the user can run this prior to upgrading f*rom* SN09 to a higher version. The script takes the *to* version as the input and lists all the devices that are not supported. The user should run this script before the upgrade and this should be documented in the steps. This script could potentially be used to interface into the upgrade manager.

Usage of the script file:

```
iems-sf2:/export/home/maint> sh
IEMSUpgradePreCheck.sh

Usage : sh IEMSUpgradePreCheck.sh <Version>

<Version> - 7 (or) 8 (or) etc..
```

Note: Do not give Version as SN07 (or) SN08 (or) etc..

Output of the script file:

iems-sf2:/export/home/maint> sh IEMSUpgradePreCheck.sh 9

```
IEMS Upgrade Pre-Check Test :

****************************

The IEMS upgrade pre-check test passed. The IEMS
upgrade may proceed.
```

```
iems-sf2:/export/home/maint> sh
IEMSUpgradePreCheck.sh 11

IEMS Upgrade Pre-Check Test :

****************************

The IEMS upgrade pre-check test Failed. The IEMS
upgrade should not proceed.

Device version check failed. The following devices
must be upgraded prior to

proceeding with the IEMS Upgrade to SN011:-

=========================================

| S.No. | Device Name       |   Version  |

=========================================

| 1     | umanand-MAS         |     8.0    |

| 2     | umanand-STORM    |     8.0    |

| 3     | USP-1328              |     8.0    |

| 4     | karanmercy-PP8600     |     8.0    |
```

In IEMS SN09, all the SN09 device versions and the previous device versions (n –2) are only supported. If any device of lower version (ex: 6.2) is found during data migration the IEMS upgrade will be aborted.

Note:

- If upgrade fails, the user needs to perform an entire restore of the backed up SSPFS image.
- If there is an MR release, the newly introduced device versions will also be taken care by this script file. For example in SN09 release the following versions will be supported.
  - 08
  - 07.1 (MR device version)
  - 07

A brief description of the different scripts involved.

92.5.5.1 Comboload Script:

This is basically the shrink-wrap script that controls the sequencing of the calls to the other scripts. It makes calls on the MFT scripts, CEM scripts, and data export scripts. It also is responsible for swapping the pam, nscd and nsswitch conf files, backing up and restoring some of the MFT conf files.It also provides warnings to users for missing SSL certs, and incorrect oracle file system sizes. The IEMS team owns this script.

92.5.5.2 MFT Script:

This script provides interfaces used by the comboload script to uninstall, install and start the MFT software. This script also takes care of the data migration. This script is not directly called by the user and is hidden in a zip file. It is unzipped and used by the comboload script. The MFT team owns this script.

92.5.5.3 CEM Script:

This script provides interfaces used by the comboload script to uninstall and install the CEM load. This script is not to be directly used by the user. The CEM team owns this script.

Data migration includes user data (security) as well as provisioning, faults, performance data. While this feature will test the combined install and upgrade, each of the subcomponents (MFT, CEM) are responsible to test their individual upgrade process and data migration and will provide input to the overall process to simplify/eliminate any manual steps involved.

Upgrade will be aborted if any devices outside the supported range are found. The Upgrade pre-check script (IEMSUpgradePreCheck.sh) will check for the non-supported devices as a first step during upgrade. Upgrades will continue only if the pre-check test gets passed.

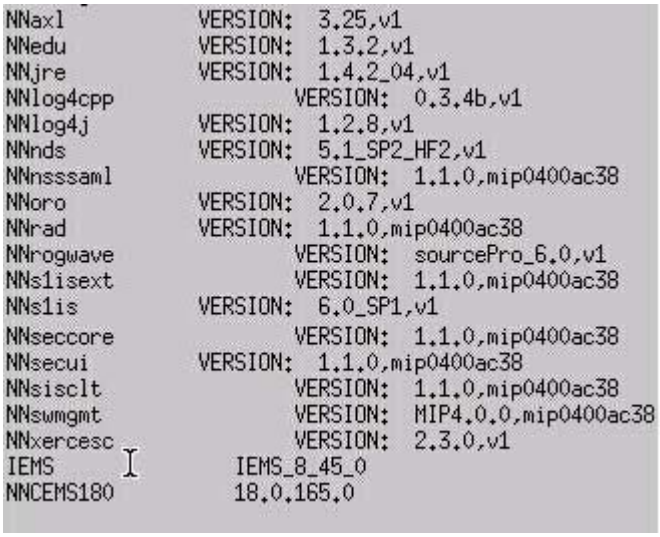
If Upgrade fails due to the presence of any non-supported devices, the user needs to follow the restore procedure to proceed.

92.5.6 SN07 – SN09 Upgrade:

For SN07 to SN08 upgrade,refer to *Upgrading a Carrier Voice over IP Network*, NN10440-450.

The comboload script file (appl_mgr.ksh) will be used to Install/Upgrade - SN09 Version of IEMS, before the IEMS SN09 server gets started the migration procedure will gets invoked.

Executing the comboload script file will display a message similar to the following screen shot.



The Upgrade process may take up to thirty minutes approximately. A message appears similar to the following screenshot:

```
Performing pkgrm on IEMS...
Successfully removed package IEMS

Installing the new security server components...
Done installing the new security server components.

==================================
Checking version of IEMS package...

Installing IEMS Package...
Done Installing IEMS Package.

Installing the CEM ...

==================================
Upgrade of the IEMS software package completed successfully
Configuring ... this may take a few minutes
Restoring backed up conf files
Configuration complete.
```

The IEMS data migration occurs in the order detailed below:

- Database Schema Migration - schema related changes
- Data Migration - device related changes needs to be handled here
- Configuration Migration - conf related changes

In case of failure in the upgrade / migration at any instance, the data and configuration changes done for the upgrade are reverted completely. The data and configuration can now be used again with the SN07 software.

92.5.7 Database Schema Migration

Database Schema Migration takes care of migration for any database schema changes that have been done for the SN09 version. Schema changes include changes such as:

- Any database tables added newly for SN09.
- Any new columns added to the existing database tables.
- Any change in the data type for the existing column in a table. Ex: Some of the columns of database tables existing in SN07 have been extended in SN09 to accommodate the additional data. Extension in column length is performed as required in SN09.

92.5.8 Data Migration

In addition to the schema changes, the format in which data is stored in the database may also have changed in the SN09 version of IEMS. In order to migrate the SN07 data to the format required in SN09, the data migration is done for the following functionalities.

1. Package name changes.
2. Rebranding.
3. Alert Filters & Event Filters conf update.

92.5.9 Configuration Migration

Changes made in Configuration files by the user at runtime while using the SN07 load will be backed up before removing the SN07 Software. And during the migration process the configuration files that were backed up earlier will be restored to preserve user changes in the new SN09 version of IEMS. Configuration files that will be backed up and restored are:

- oidtemplates – All XML files present in the oidtemplates directory will be backed up while uninstalling SN07 and restored at SN09 migration
- logging_parameters.conf
- event.filters
- alert. filters

92.5.10 Rollback

If the upgrade to the newly installed version of software fails before the point of no return (before executing the clean up scripts), all the changes done for migrating the data are reverted to the original state.

If failure occurs during Upgrade the following steps needs to be followed for a complete rollback:

- Downgrade SSPFS platform.
- Import Integrated EMS data (Integrated EMS, CEM).
- Restart MS20x0 application (for co-resident).

92.5.11 SN08 - SN09 Upgrade

The comboload script file (appl_mgr.ksh) will be used to Install/Upgrade - SN09 Version of IEMS, before the IEMS SN09 server gets started the migration procedure will gets invoked.

Executing the comboload script file will display a message similar to the following screen shot.

```
NNaxl          VERSION:  3.25,v1
NNedu          VERSION:  1.3.2,v1
NNjre          VERSION:  1.4.2_04,v1
NNlog4cpp              VERSION:  0.3.4b,v1
NNlog4j        VERSION:  1.2.8,v1

NNxercesc              VERSION:  2.3.0,v1
IEMS           IEMS_8_45_0
NNCEMS180      18.0.165.0
```

The Upgrade process may take up to thirty minutes approximately. A message appears similar to the following screenshot:

```
Performing pkgrm on IEMS...
Successfully removed package IEMS

Installing the new security server components...
Done installing the new security server components.

==================================
Checking version of IEMS package...

Installing IEMS Package...
Done Installing IEMS Package.

Installing the CEM ...

==================================
Upgrade of the IEMS software package completed successfully
Configuring ... this may take a few minutes
Restoring backed up conf files
Configuration complete.
```

The IEMS data migration occurs in the order detailed below:

- Database Schema Migration - schema related changes
- Data Migration - device related changes needs to be handled here
- Configuration Migration - conf related changes

In case of failure in the upgrade / migration at any instance, the data and configuration changes done for the upgrade are reverted completely. The data and configuration can now be used again with the SN08 software.

92.5.12 Database Schema Migration

Database Schema Migration takes care of migration for any database schema changes that have been done for the SN09 version. Schema changes include changes such as:

- Any database tables added newly for SN09.
- Any new columns added to the existing database tables.
- Any change in the data type for the existing column in a table. Ex: Some of the columns of database tables existing in SN08 have been extended in SN09 to accommodate the additional data. Extension in column length is performed as required in SN09.

92.5.13 Data Migration

In addition to the schema changes, the format in which data is stored in the database may also have changed in the SN09 version of IEMS. In order to migrate the SN08 data to the format required in SN09, the data migration is done for the following functionalities.

- Package name changes.
- Rebranding.
- Alert Filters & Event Filters conf update.

92.5.14 Configuration Migration

Changes made in Configuration files by the user at runtime while using the SN08 load will be backed up before removing the SN08 Software. And during the migration process the configuration files that were backed up earlier will be restored to preserve user changes in the new SN09 version of IEMS. Configuration files that will be backed up and restored are:

- oidtemplates – All XML files present in the oidtemplates directory will be backed up while uninstalling SN08 and restored at SN09 migration
- logging_parameters.conf
- event.filters
- alert. filters

92.5.15 Rollback

If the upgrade to the newly installed version of software fails before the point of no return (before executing the clean up scripts), all the changes done for migrating the data are reverted to the original state.

If failure occurs during Upgrade the following steps needs to be followed for a complete rollback:

- Downgrade SSPFS platform.
- Import Integrated EMS data (Integrated EMS, CEM).
- Restart MS20x0 application(for co-resident).

93: Functional Description(FN): A00009651

93.1 Feature name and Feature ID

A00009651: Meet Me Web Collaboration Multilingual

93.2 Description

93.2.1 Background

Meet Me Web Collaboration was introduced as a Fast Feature in the MCS 3.0 release and only supported English on the collaboration web pages presented to users. This activity incorporates the FTR 424 Fast Feature into the 9.0 release and enhances it by adding multilingual support for the collaboration web pages.

93.2.2 Overview

Web Collaboration allows people in different locations to view a PC generated presentation over the IP based network. The initial release of Web Collaboration did not include support for multiple languages. It is expected to provide the same languages supported within other portions of MCS.

In prior releases, MCS users have had the ability to select language preferences both as personal preferences for their PA, and by dialing Meet Me alias numbers that are associated with a specific language. This feature extends the language choice indicated by the Meet Me alias dialed, to the Web Collaboration GUI (tool tips and dialog boxes, and user help). As a result, the audio prompts of the conference and the display on the collaboration web pages will be in the same language. It is not intended to translate the presenter’s presentation.

Below is the list of languages supported in MCS 09. Meet Me Web Collaboration supports the same set of languages as the other MCS network components

1. English
2. Parisan French
3. Latin America Spanish
4. German
5. Japanese
6. Traditional Chinese
7. Simplified Chinese
8. Korean

93.3 Feature Description

93.3.1 Operator Configuration and Provisioning

This section presents Meet Me Web Collaboration configuration and provisioning information needed by operators and installers of the MCS solution.

93.3.1.1 Installation

Each Web Collaboration server must be configured with the required collaboration software. The major applications which will be installed are listed below.

- Microsoft Server 2000: Operating System (custom OS image is included on the hardware when ordered).
- Web Collaboration Application: Server side Web Collaboration software
- Provider Supplied:
  - Microsoft Office 2003: Office productivity Application suite required for collaborative document presentation (Word, PowerPoint and Excel)
  - MSDE 2000: Database required for run time collaboration data storage
  - IIS: Web Server
  - MS Internet Explorer 6.0
  - SSL 128 Certificates for HTTPS

93.3.2 Administrator Configuration and Provisioning

This section presents configuration and provisioning information needed by the system administrators for daily service and end-user support.

No new configuration or provisioning tasks are added.

93.3.3 Feature Provisioning

There are no new Meet Me Web Collaboration configuration options available to the end-user. However, all the existing Meet Me options a user has in their Personal Agent also apply to Meet Me Web Collaboration sessions. The user's language selection for their Meet Me Conference and Collaboration session is determined by the ALIAS dialed. The available Alias's are listed for a user in there PA under their Meet Me Preferences (language specific Meet Me aliases are not a new feature).

93.3.4 Feature Behavior

93.3.4.1 Overview

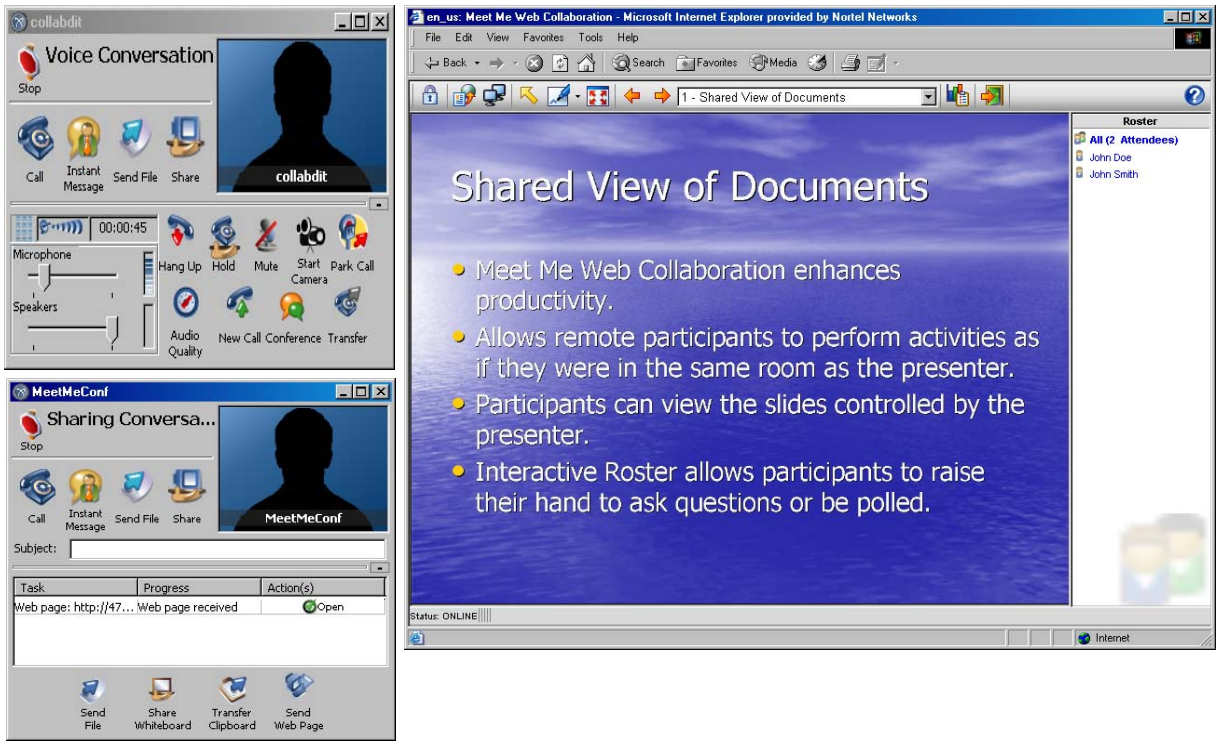
Language selection and use in the collaboration session is based upon Meet me Conference **alias a user dials**. The available aliases are listed for a user in their

PA under their Meet Me Preferences (language specific Meet Me aliases are not a new feature). Prior to the Multilingual Support for Web Collaboration, only the audio prompts reflected the language indicated by a dialed alias. N**ow the Collaboration session will also reflect the language indicated by the dialed alias**.

In addition to multilingual support, a few other enhancements are introduced. as outlined in this section.

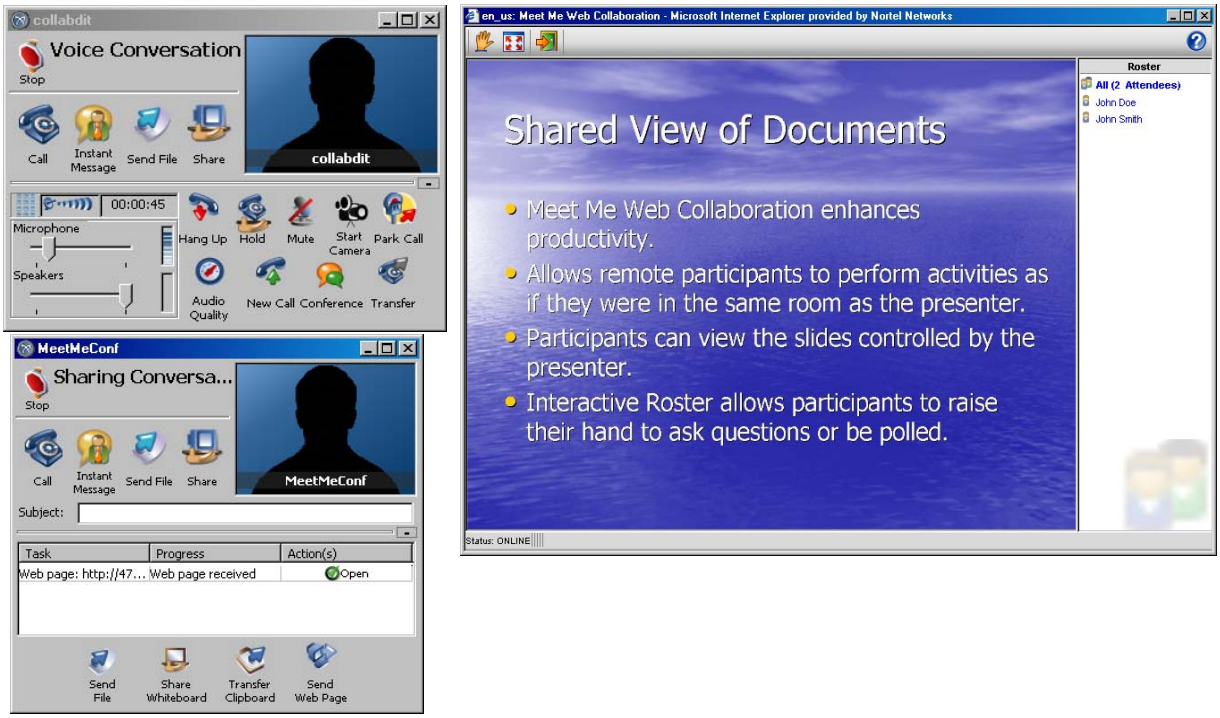
There have been some minor graphical updates to the displays as shown in the following figures.

Figure 1: Presenter's Client Call Control Window and View of Published Material



The participants now have a roster showing other participants. The main difference between the presenter and participant windows is the options available on the tool bars.

Figure 2: Participant's Client Call Control Window and View of Published Material



The publish interface has been changed and enhanced. There is a new window for publishing and the presenter (chairperson) may now login early and prepublish 1-30 documents. A presenter can then quickly jump between documents with out waiting for the uploading and conversion process of publishing. (All the documents are deleted when the Collaboration session is ended.).

To publish a document:

1 From the Presenter toolbar, click the Publish Documents icon . The "Publish Documents window is displayed.

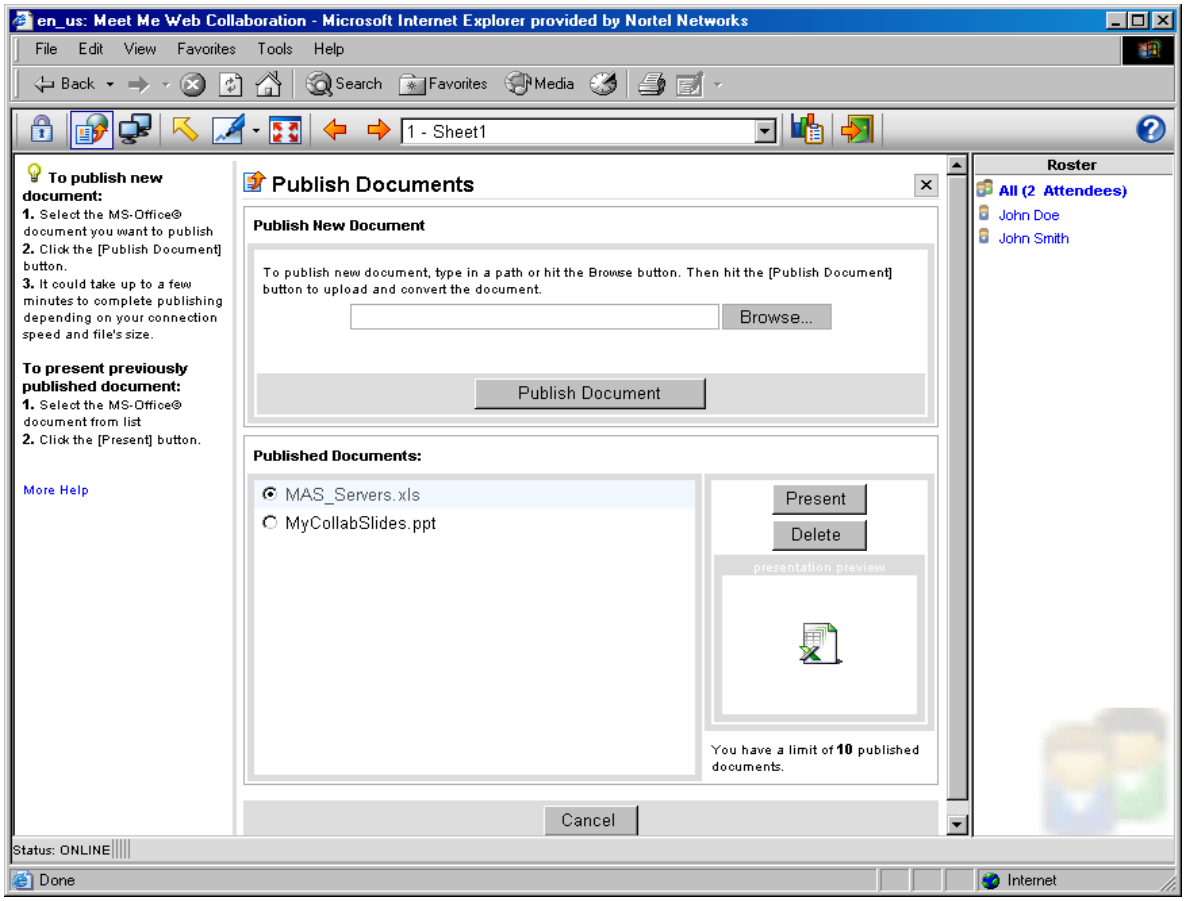
2 Click Browse, navigate to the directory containing the document to publish, and select the document.

3 Click Open.
The user is returned to the "Publish Documents" window and the full path to the document is displayed.

4 Click Publish Document.
The document is displayed in the main window. Note that uploading a document can take several minutes, depending on the speed of the network connection and the size of the document.

When the presenter is finished with one document, they may click the Publish Documents icon to return to the Publish New Document window to publish or present other documents.

Figure 3: Presenter Publishes Content



The presenter uses the above window to publish and manage published documents during a collaboration session. Office documents are published by using the Browse… button, selecting a file and then pressing the Publish Document button. Once this is done, the “Published Documents:” panel shows all the documents ready to present. A radio button allows selection of a particular document. The buttons Present and Delete perform the corresponding action on the selected document. All documents are deleted when the collaboration session ends.

The collaboration tool bars have been internationalized. The English labels under each button have been removed and replaced with hover help text which displays in the users language. The tool bar buttons also have a new graphic look and are defined below.

The Web Collaboration presenter's window has a tool bar with controls for the presentation. The following functionality is available to the presenter on the Presenter's Tool bar:

	Publish	Allows the presenter to specify the file to be published. After selecting the desired file the document is converted to a web publishable HTML format.
	Share	Allows the presenter to graphically share the view of any running program on their computer with participants.
	Point	Provides the presenter with an active mouse controlled pointer for the published document.
	Marker	Provides mouse annotation tool for the published document. All participants can see the resulting mark-ups.
	Full Screen	Toggles Full-Screen mode. When the presenter uses this button, the presenter's and all participants' collaboration screens switch to full screen mode. If the present toggle Full Screen Mode off, only his screen is normalized.
	Previous	Navigation to the previously displayed document page.
	Next	Navigation to the next document page.
	Content Selector	The Content Selector displays slide numbers and titles in a selectable drop down list providing the ability to quickly jump between slides.
	Poll	Launches a polling mechanism which allows the presenter to enter a question and multiple choice answers and get instant tabulated results.
	Exit	Ends the collaboration Session
	Help	Online user help.
	Lock	Locks the web portion of the collaboration session so that no new users may join. Does not impact the audio portion of the conference.

The Web Collaboration participant's window contains a toolbar with the following functionality:

	Raise Hand	Allows the participants to toggle “raising their hand.” The presenter’s roster shows a raised hand icon next to the participant’s name.
	Full Screen	Allows a participant to enter/exit the full screen collaboration mode (only for their own screen). Note: The presenter can force all participants to full screen, but then the participants may individually normalize their screens as desired.
	Exit	Removes participant from the collaboration session. The Meet Me Audio conference connection is unaffected.
	Help	Online user help.

93.4 Dependencies

93.4.1 Hardware Dependencies

IBM X335 or X336 eServers and the IBM Blade Center and Blade Center-T hardware may be used for the Web Collaboration Servers. Previous to this feature only the X335 eServer was supported.

93.4.2 Software Dependencies

93.4.2.1 Nortel Networks Software Dependencies

Not Applicable

93.4.2.2 Non-Nortel Networks Software Dependencies

Clients

Joining Conferences

The personal computers of people joining the collaboration session must meet the following minimum requirements to view published pages:

- 56kbps or higher connection speed is recommended
- Microsoft Windows 98/NT/ME/2000/XP/Server2003 with Internet

Explorer 5.5 or higher (preferred), Netscape 7.1 or higher.

- Cookies, Pop-Ups and Scripting Enabled in web browsers.

Application & Desktop Sharing

For application and desktop sharing, the sharing system must meet the following additional requirements:

- Microsoft Windows 98/NT/ME/2000/XP/Server2003 System with Internet Explorer 5.5 or higher
- Ability to run ActiveX sharing controls or pre-install sharing components
- 128kbps or higher connection speed is recommended
- The Microsoft or Sun JVM maybe used. A Java Virtual Machine 1.5 or higher is required to view or control shared screens (Windows NT systems should use Microsoft or Sun JVM 1.4.2_03). The latest service pack and patches should be applied to all Windows operating systems.

Servers

Table 2: External Software Dependencies

Component	External Dependency	Description
Media Application Server	Microsoft Windows Server 2000	Operating System
Collaboration Server	Microsoft Windows Server 2000	Operating System
Collaboration Server	Microsoft Office 2003 (All components except Access and Outlook)	Office productivity Application suite
Collaboration Server	Microsoft MSDE 2000	Database
Collaboration Server	Microsoft IIS	Web Server
Collaboration Server	Microsoft Internet Expoler 6.0	Web Browser

93.4.3 Network Component Dependencies

93.4.3.1 Nortel Networks Components

Interactions remain as described in FTR 424 Meet Me Web Collaboration.

93.4.3.2 Non-Nortel Networks Components

Not Applicable

94: Functional Description(FN): A00009655

94.1 Feature name and Feature ID

A00009655: BladeCenter-T RTP Media Portal

94.2 Background

The RTP Media Portal has been a part of the Multimedia Communications Portfolio (MCP) since its inception. The RTP Media Portal was a pooled resource that provides a variety of media-plane functions to MCP solutions including:

- Firewall and NAPT (FW/NAPT) Traversal for obscured endpoints.
- Media-Plane Firewall to protect sensitive components in the service network.
- Media Anchor/Pivot capabilities that enable media-stream manipulation without the involvement of a participating endpoint.
- Replication of media streams for CALEA.

The introductory version of the RTP Media Portal was delivered as a distributed set of subcomponents that ran on the carrier-grade Motorola CPX8216T hardware chassis. The Motorola CPX8216T chassis is a compact PCI (cPCI) architecture that provided the environmental requirements for the processing blades on which the distributed RTP Media Portal subcomponents executed. The Motorola CPX8216T chassis was partitioned into two separate PCI control domains that enabled two RTP Media Portals to reside in a single chassis. Each of these PCI control domains support the hardware components that constitute a RTP Media Portal:

- A CPV5370 Intel processor board (the Host card) with 1 GB memory, a SCSI input/output (IO) daughter board, and rear Transition Module.
- One (or more) Motorola MCPN765 Power PC processor board (the Media Blade), with 64 MB RAM and associated Rear Transition Module.
- The Hot Swap Controller and Bridge (HSC) modules.
- SCSI CD-ROM drive.
- SCSI hard drive.
- Floppy drive.

From one perspective the introductory version of the RTP Media Portal had a software architecture that closely matched the hardware architecture. However, it was also designed to be portable so that it would be platform-agnostic and poised to benefit from the advances provided by Moore’s Law.

Since its first introduction, the RTP Media Portal has fared well and proven itself to be a stable component of the MCP solution. Unfortunately, the maturation of the Voice-Over-IP (VoIP) market has begun to stress some of the first generation RTP Media Portal's limitations:

- Need for higher density (more media flows per unit of rack space).
- Need for more media bandwidth than can be provided by the dual 10/100 Mbps Ethernet links on the MCPN765 Media Blade.
- Need for improved supportability (PPC Linux).
- Need for improved reliability strategy.

The demands of the market, the benefits being reaped by other MCP components that were migrating onto the IBM BladeCenter-T platform, and the synergies that could be realized by being able to deliver all MCS components on the same platform, came together in the program to evolve the RTP Media Portal and migrate it to the IBM BladeCenter-T platform. Migration to the IBM BladeCenter-T platform provides many benefits:

- Component simplification.
- Increased capacity.
- Decreased footprint.
- Decreased cost-per-port.
- Commonality with other components (e.g. MAS, and MCS Linux Port).

94.3 Overview

The evolution to the second generation Media Portal involves the following activities:

- Migration to the IBM BladeCenter-T platform.
- Rearchitecture of the RTP Media Portal software.
- Introduction an N+1 (N-active and 1-standby) fault tolerance strategy.

94.3.1 Migration to the IBM BladeCenter-T Platform

The IBM BladeCenter-T (Type 8720 – DC Power) unit is based on proven off-the-shelf IBM Enterprise X-Architecture technologies.

The BladeCenter-T unit is a rack-mounted, high-density, high-performance blade- server system developed for NEBS telecommunications network applications and other applications requiring additional physical robustness.

The BladeCenter-T unit uses Blade Servers, switches, and other components that are common to the IBM BladeCenter product line. This common component strategy makes it ideal for applications in telecommunications

networks that need high levels of computing power and access to common off-the-shelf middleware packages that are used in IT data centers.

The BladeCenter-T unit supports up to eight Blade Servers, making it ideally suited for networking environments that require a large number of high-performance servers in a small amount of space.

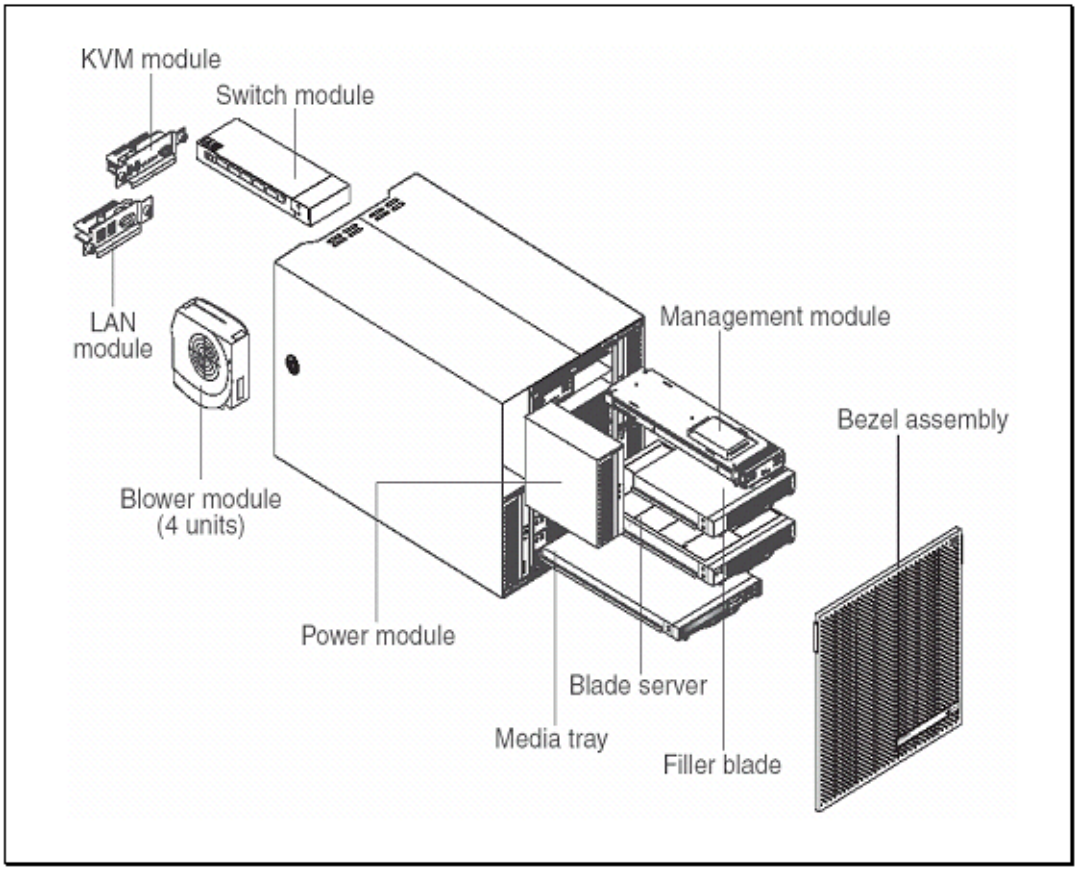
The BladeCenter-T unit provides common resources that are shared by the Blade Servers, such as power, cooling, system management, network connections, backplane, and IO (CD-ROM drive and connectors for USB, keyboard, video, mouse, and network interfaces). Refer to Figure 1 on the following page.

Performance, ease of use, reliability (NEBS/ETSI compliance), and expansion capabilities were key considerations in the design of the BladeCenter-T unit. These design features make it possible for you to customize the system hardware to meet your needs today, while providing flexible expansion capabilities for the future.

This feature activity ports the MCP RTP Media Portal component on to these Blade Servers - expanding the commonality of the IBM BladeCenter-T in MCP technology. In another move towards technology consolidation this feature also up-versions the Operating System upon which the RTP Media Portal runs to Red Hat Linux Advanced Server 3 (AS3). This is the Operating System utilized by other MCP components and its adoption by the RTP Media Portal contributes to further simplification of the overall solution.

You can obtain up-to-date information about the BladeCenter-T Type 8720 product at http://www.ibm.com/eserver/xseries/.

Figure 1: IBM BladeCenter-T Chassis (8720 – DC Version) Exploded View



94.3.2 Rearchitecture of the TRP Media Portal Software

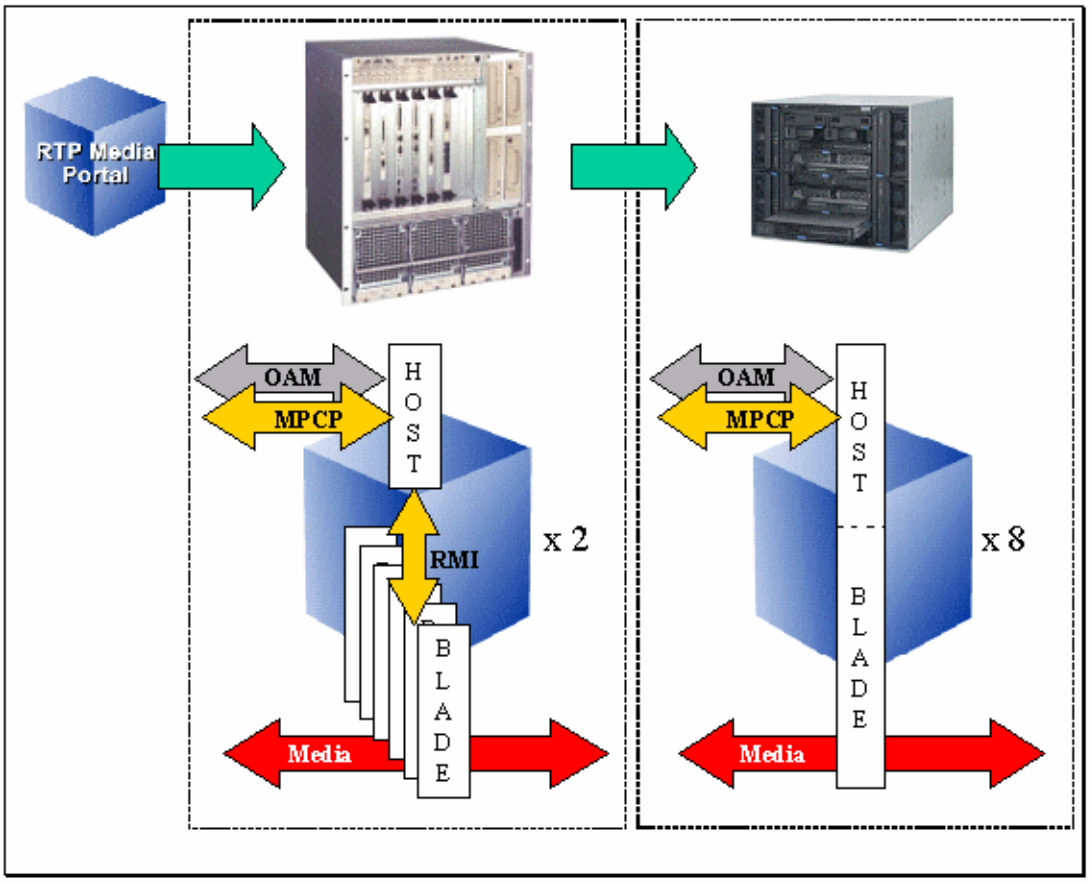
The migration from a distributed hardware architecture to a new hardware architecture that consolidates all service functionality onto a single hardware component necessitated a re-architecture of the internal software that comprises the RTP Media Portal and the services it provides.

The RTP Media Portal software was originally architected to operate in a distributed system (with a single Host communicating over the network to one or more Media Blades). This architecture has been enhanced so that the software will properly configure itself to conform with the operating environment of the target platform: it will either initialize as a distributed collection of networked sub-components (i.e. a Host communicating to one or more Media Blades), or as a consolidated amalgamation of Host and Media Blade functions into a single entity. Refer to the following figure.

The consolidation of Host and Media Blade functionality into a single entity also results in simplification through the elimination of the internal

complexities involved with coordinating service delivery amongst many distributed elements.

Figure 2: RTP Media Portal Platform Migration: Overview of Software Architectures



94.3.3 Introduction of N+1 Fault Tolerance Strategy

The original RTP Media Portal reliability strategy was to treat the RTP Media Portal as a pooled resource. Each RTP Media Portal was configured to advertise its availability to provide service to a set of Call Servers. The Call Servers would place each available RTP Media Portal into a media resource pool that would be used to serve-up available media resources during call processing.

In this manner traffic was distributed over many RTP Media Portals which lessened the impact of a failure. While lessening the impact of most failure conditions, this strategy did not preserve media sessions that existed on a piece of failed hardware. As a result, there are failure scenarios for the original RTP Media Portal that could result in loss of active calls (in the case of a Media Blade failure this could mean the loss of 400 calls, in the case of a single

chassis domain failure 2400 calls could be lost, and in the case of a full chassis failure there could be up to 4800 calls lost).

Simplification of the software architecture afforded an opportunity to take a quantum leap forward in terms of the fault tolerance attributes of the RTP Media Portal when it executes on the IBM BladeCenter-T platform. The consolidation of both Host and Media Blade functions into a single entity greatly reduced the complexity of providing the N+1 fault tolerance capabilities delivered by this feature.

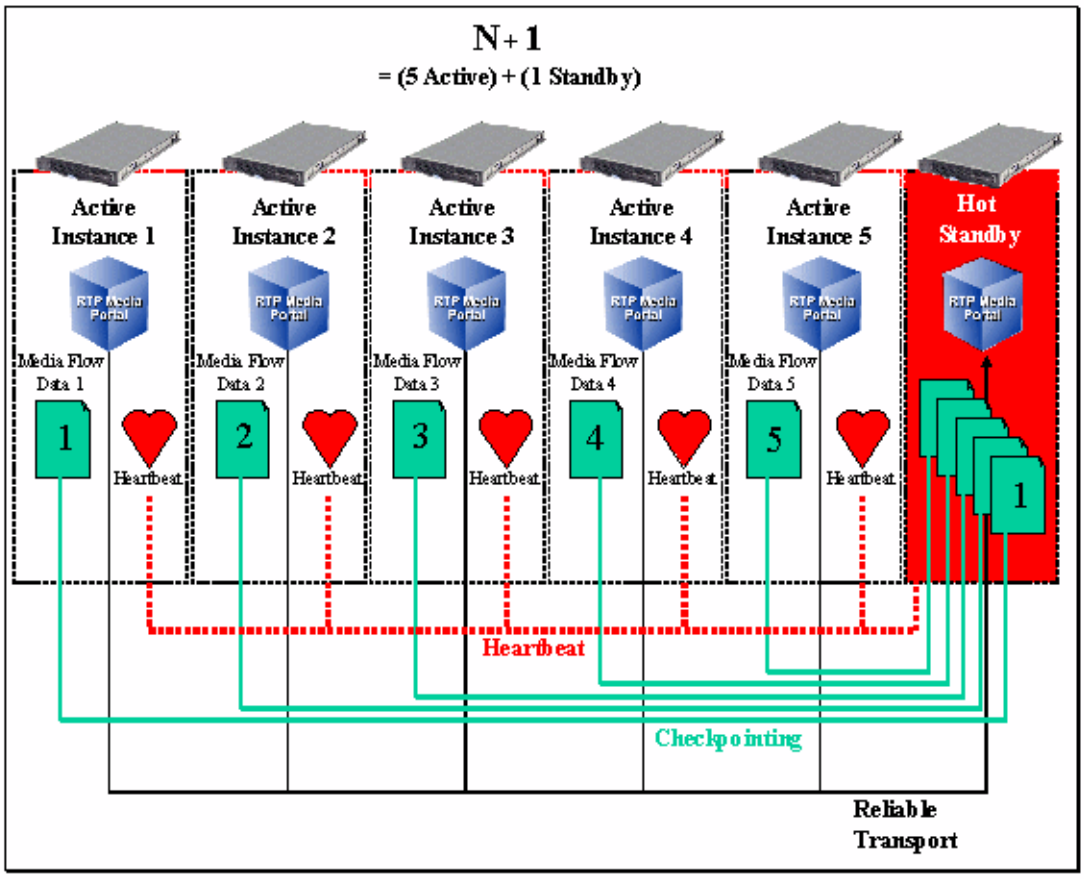
The N+1 fault tolerant RTP Media Portal is achieved through the creation of fault tolerant service clusters that define a set of RTP Media Portal instances (the “N” logical service instances) and that identifies the target servers that host the instances (“N” servers to run the active service instances and an additional server that runs a standby service instance). In this way a fault tolerant RTP Media Portal is provided that is able to have active media sessions survive the catastrophic failure of a single instance of the service by having a “standby” instance that is ready-and-able to takeover all media sessions that were hosted on the failed instance. Refer to Figure 3 on the next page.

The N+1 fault tolerant capabilities of the RTP Media Portal are built upon a reliable messaging framework that ensures connectivity between cluster members. The operating context of the cluster members is established through an election protocol that runs over the reliable messaging framework to dynamically determine which servers will be running active instances of the RTP Media Portal – and which server will be running the standby instance. This operating context is maintained through use of a heartbeat mechanism that continuously validates the state of members in the cluster. Once the cluster is formed, all state data for each active media stream (on each active instance of the RTP Media Portal in the cluster) is checkpointed to the standby RTP Media Portal instance. In this way, the standby instance remains synchronized with all active instances and is thereby ready to takeover processing of the sessions for any of those instances should a failure occur.

The N+1 takeover process is transparent to the endpoints that are originating and terminating the media streams relayed through the failed instance. This is because the standby instance begins receiving and relaying those same media streams as soon as the failure is detected and takeover is affected.

Initially, N+1 fault tolerance capabilities are restricted to the confines of a single IBM BladeCenter-T chassis. This enables configuration of fault tolerant clusters as small as 1+1 (“1-active-instance” + “1-standby-instance”) and up to as large as 7+1 (“7-active-instances” + “1-standby-instance”).

Figure 3: RTP Media Portal N+1 Fault Tolerant Service Cluster (example 5 active +1 standby configuration)

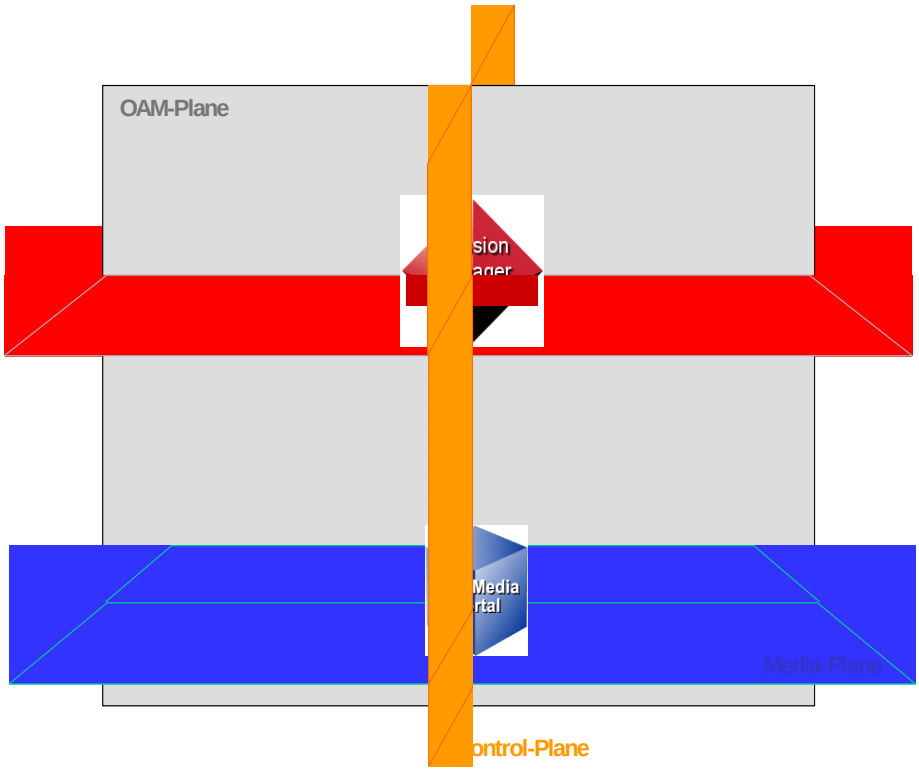


94.4 Functional Description

94.5 Overview

The RTP Media Portal has always existed in the Control-plane, the Management-plane, and the Media Plane. Refer to the following figure.

Figure 4 Legacy RTP Media Portal Presence in Service-planes

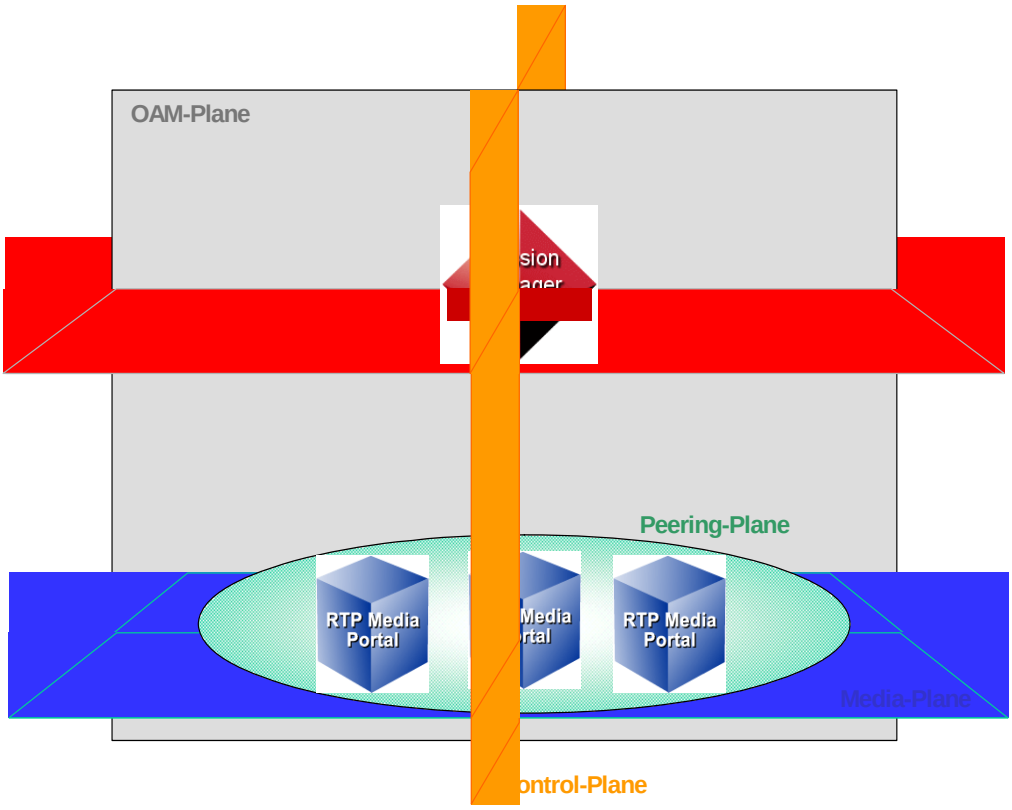


The BladeCenter-T RTP Media Portal continues to have presence in the Control, Management, and Media service-planes thus appearing (from a macro-level) to be the same as established legacy deployments to the outside world. Refer to the figure that follows. While appearing the same to the outside world, the BladeCenter-T RTP Media Portal does introduce some change as to how it is present in each of the service-planes at a sub-atomic level (not visible to the outside world):

- The BladeCenter-T RTP Media Portal has abstracted the RTP Media Portal Service from the platform. So, in fact the BladeCenter-T RTP Media Portal consists of an RTP Media Portal Service (which resides in the Control-plane and the Media-Plane), and a separate BladeCenter-T Platform (which resides in the Management-plane). This architectural change enables the BladeCenter-T RTP Media Portal to have separate and distinct points of presence in the Control-plane (the Controlipaddr), the Management-plane (the Blade Server's physical IP address), and the Media-plane (Net1MediaIP and Net2MediaIP). Previously, the RTP Media Portal was a tight coupling of hardware and software configuration that constituted a single point (the Host IP address – which was also the Server's physical IP address) through which the RTP Media Portal participated in the service-planes.

- The introduction of N+1 Fault Tolerance with the BladeCenter-T RTP Media Portal has created a new service-plane (orthogonal to all others) to support Intra-Cluster Service Communications as part of the N+1 Fault Tolerance Framework. This new service-plane is called the Peering-plane.

Figure 5 BladeCenter-T RTP Media PortalPresence in Service-planes



By retaining presence in the service-planes, and making changes that are not visible to the outside world, the BladeCenter-T RTP Media Portal maintains compatability with legacy configurations:

- The BladeCenter-T RTP Media Portal appears identical from the perspective of the MCS Management Server as viewed in the Management-plane. This is accomplished transparently as the BladeCenter-T RTP Media Portal utilizes the pre-existing RTP Portal Network Element as its point of attachment to the Management-plane:
  - the BladeCenter-T RTP Media Portal is deployed using the RTP Portal Network Element,
  - the BladeCenter-T RTP Media Portal conveys telemetry (Logs, Alarms, and Operational Measurements) through the RTP Portal Network element,

- and the BladeCenter-T RTP Media Portal is managed (Start, Stop, Kill) through the RTP Portal Network Element.

- The BladeCenter-T RTP Media Portal appears identical from the perspective of the controlling Call Server as viewed in the Control-plane because it supports the same version of the Media Portal Control Protocol (MPCP) that is supported by legacy systems.
- The BladeCenter-T RTP Media Portal also provides the same media-layer functions as provided in legacy systems and so appears identical in terms of Media-plane capabilities.

Note: There is a new RTCP CNAME screening capability introduced into the Media-plane as part of this feature activity. This new capability was implemented as part of the Media Packet Engine – and so is common to both legacy and BladeCenter-T RTP Media Portals. Thus compatability, and equivalence is maintained across platforms.

94.6 BladeCenter-T RTP Media Portal Service Instantiation

94.6.1 Overview

The following activities must be performed in order to deploy the RTP Media Portal to actively provide service in the network:

1. Installation and Commissioning of the base hardware (IBM BladeCenter-T) and software (Red Hat Advanced Server 3) platforms. This ensures proper cabling, network connectivity, and IP address assignments. Refer to “The BladeCenter-T RTP Media Portal Installation and Commissioning Guide”[1] for detailed information on the installation and commissioning procedure.
2. Configuration of the Service. (Refer to the "Configuration” section of this feature.)
3. Deploy the Service software to distribute the service logic to each of the Blade Servers participating in the Service Cluster.
4. (Finally) The Service Instance must be started (the START command must be issued from the Management Console) in order for instatiation to occur and service to be provided.

The Deploy and Start activities are described in more detail in the following sections.

Note: Deploy and Start are very similar for Stand-Alone and Service Cluster configurations, but each will be described separately for completeness.

94.6.2 Stand-Alone RTP Media Portal Instance

94.6.2.1 Stand-Alone Instantiation

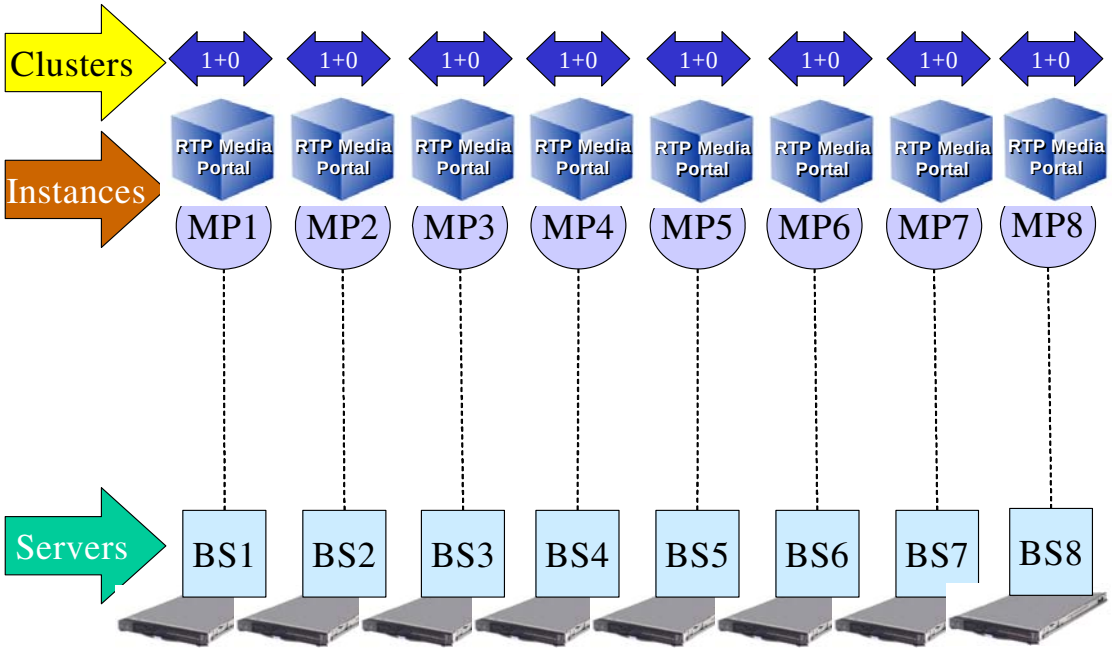
This section describes the deployment of Service software and the start-up of the RTP Media Portal service for a Stand-Alone RTP Media Portal Service Instance. The deployment phase places the Service software on the target Blade Server, and the start phase causes the instantiation of run-time structures so that the Stand-Alone RTP Media Portal Service Instance can become active and begin providing service.

The Stand-Alone RTP Media Portal Service is a single non-redundant instance of the service that runs independently of all other instances. Even though the Stand-Alone RTP Media Portal Instance is operationally different from the RTP Media Portal Service Cluster in a number of ways, it is configured as if it were a “1+0” Cluster – that is one (1) active service instance and zero (0) standby instances.

One characteristic that distinguishes a Stand-Alone RTP Media Portal Instance from an RTP Media Portal Service Cluster is that the stand-Alone Instance is only configured with one element of Service Instance Data (in Network Data => Clusters). When instantiated this effectively creates as one-to-one association of the Stand-Alone RTP Media Portal Service Instance with the target Blade Server.

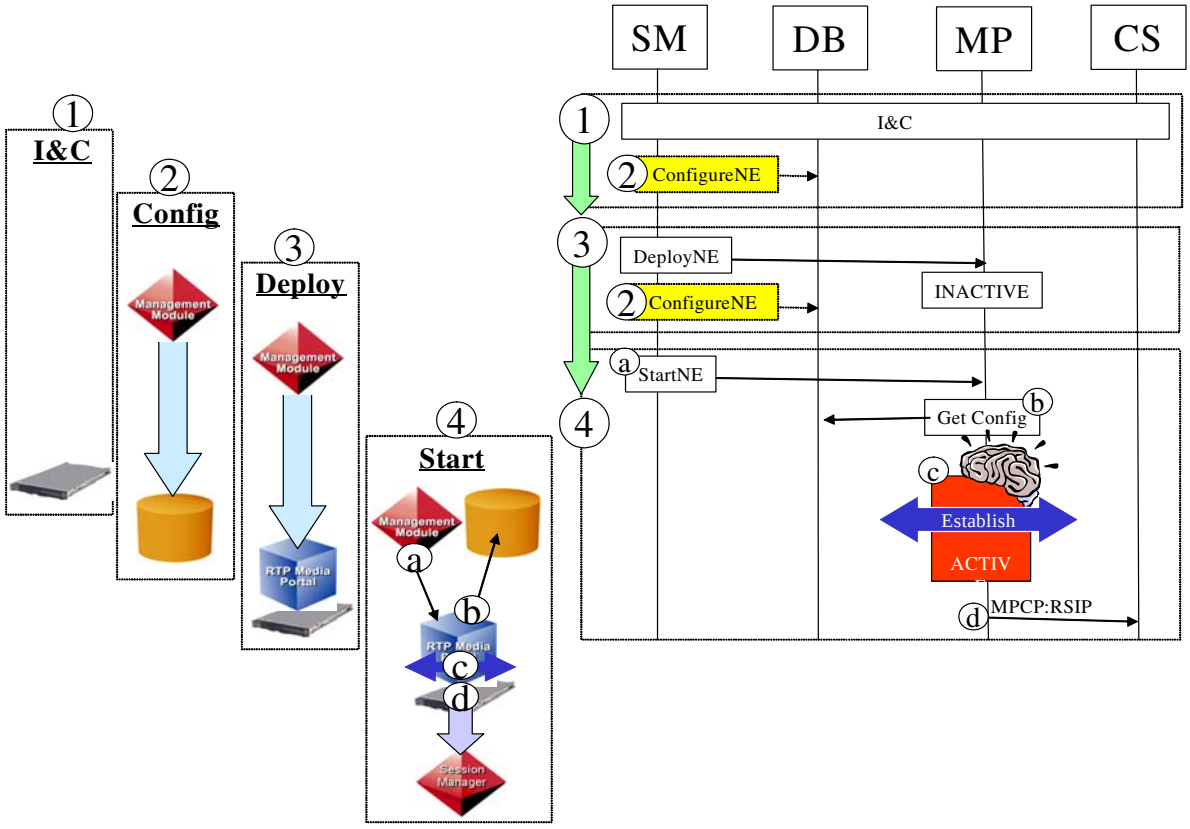
A single BladeCenter-T chassis can host up to eight (8) Stand-Alone RTP Media Portal Instances (refer to the following figure).

Figure 6 Stand-Alone RTP Media Portal Service Instances (Logical View)

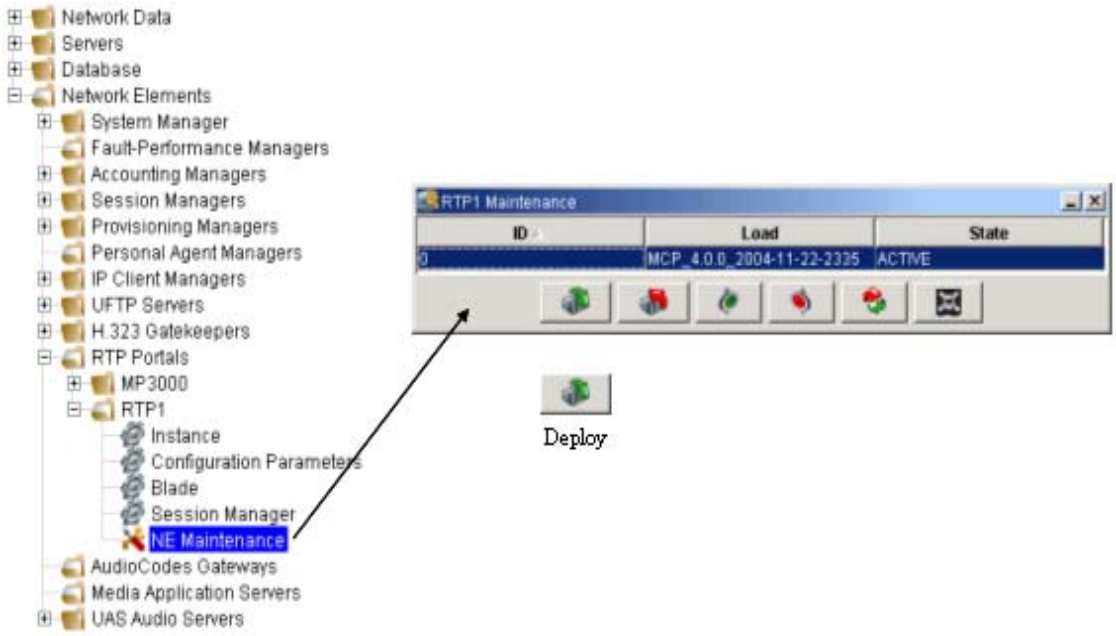


The following figure is provided as reference for the activities to be discussed that are performed in in the course of introducing a new Stand-Alone RTP Media Portal Service Instance into a site.

Figure 7 RTP Media Portal Service Deploy

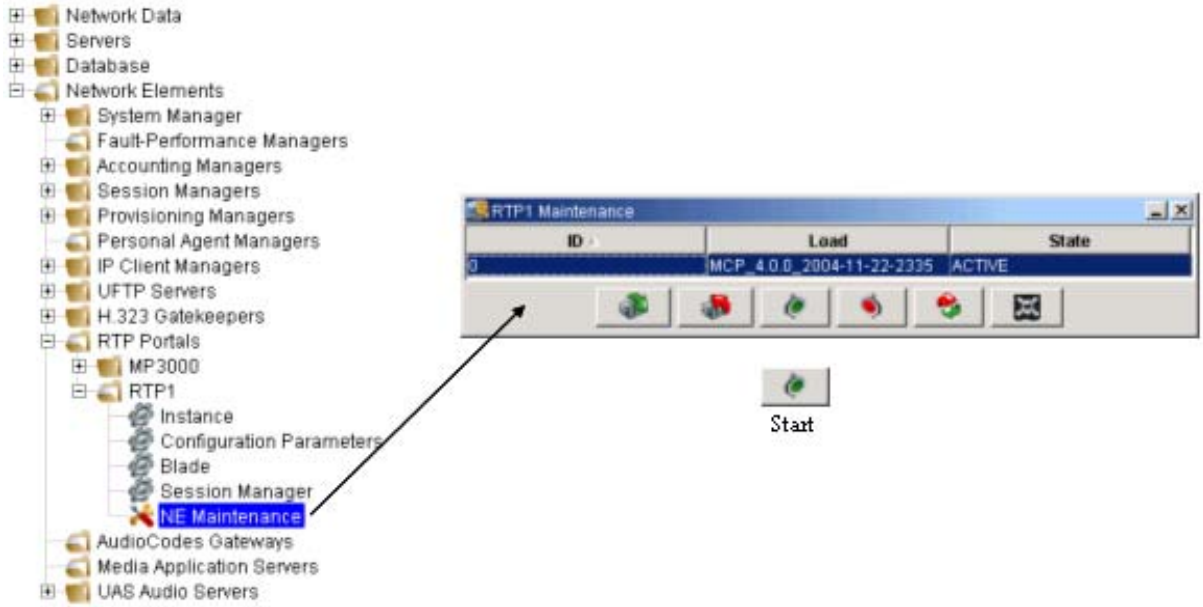


1. Installation and Commissioning of the base hardware and software platforms. Refer to “The BladeCenter-T RTP Media Portal Installation and Commissioning Guide”[1] for detailed information on the installation and commissioning procedure.
2. Configuration of the Service. The RTP Media Portal Service configuration can be changed at any time but (for the most part) is only picked up by the service on start-up. Refer to section “Service Configuration.”
3. Navigate the Management Console to the RTP Portal Network Element representing the Blade Server participating in this “1+0” Service Cluster (this will be the only RTP Portal NE that has been configured to participate in this Cluster – making it a Stand-Alone). Open the NE Maintenance window and click the Deploy button to dispatch all Service software to the Blade Server:



4. Once successfully deployed the Service Instance must be started so that instantiation of the run-time structures occurs and the service can be offered:

   a. Once again, navigate the Management Console to the RTP Portal Network Element representing the Blade Server participating in this "1+0" Service Cluster. Open the NE Maintenance window and click the Start button to start-up a RTP Media Portal Service Instance on this Blade Server:



b. As the RTP Media Portal Service Instance on the target Blade Server begins to come into service it retrieves its configuration data from the MCS Database Server. The RTP Media Portal Service Instance determines that it is configured to participate in a Cluster and then locates the specific Cluster configuration in the Network Data. Instantiation then proceeds using the Cluster Network Data to configure the service.

c. Some of the first processes started by the RTP Media Portal Service Instance are those that support the N+1 Fault Tolerant Framework (i.e. they allocate the configured multicast address and port, start the reliable messaging framework to open the intra-cluster communications channel, etc.). As the N+1 Fault Tolerant Framework Processes come up they establish the Cluster in run-time. Since this is the first RTP Media Portal Service Instance in the Cluster it is determined to be an active instance.

d. Once a RTP Media Portal Service Instance is set to active state, it issues MPCP RSIP messages to all of its configured Call Controllers (as configured in the Cluster Network Data) in order to advertise its ability to provide service. After this point the RTP Media Portal Service Instance will be called upon to service calls.

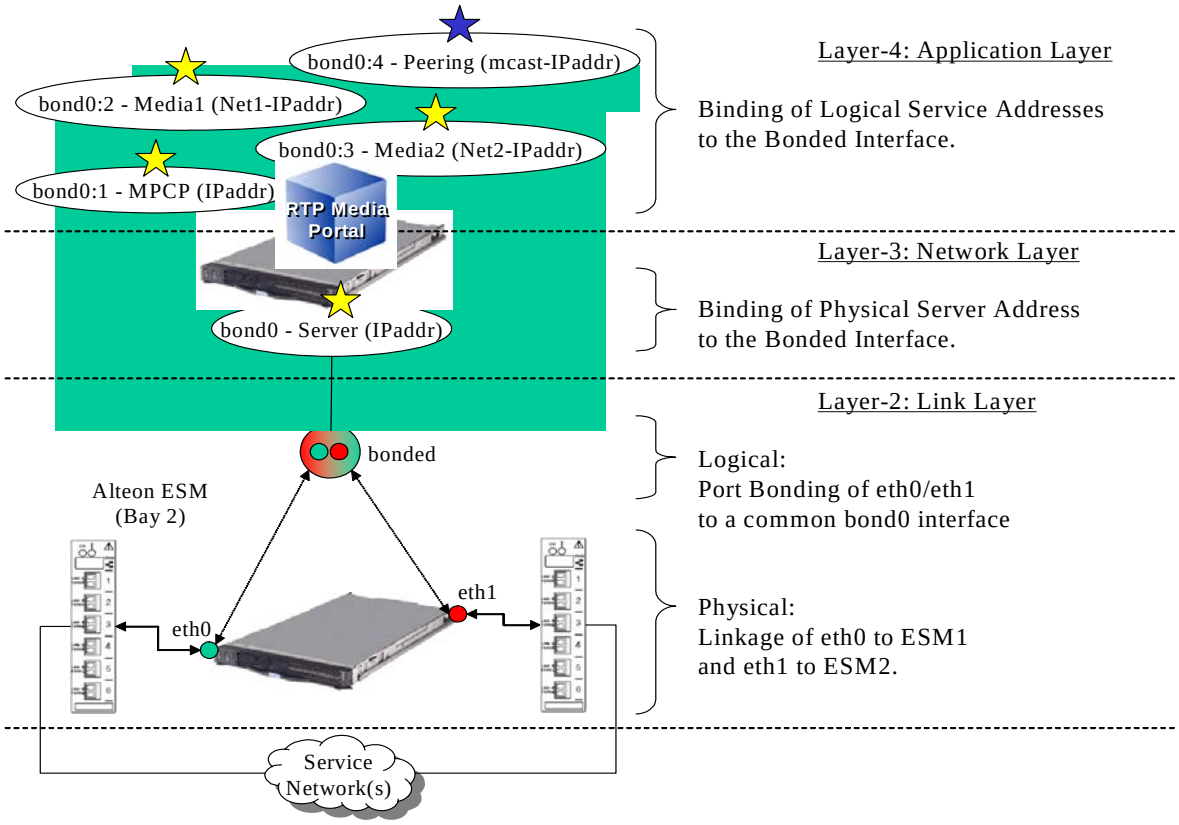
94.6.2.2 Stand-Alone Run-Time

Once instantiated the Stand-Alone RTP Media Portal Service Instance consists of the following run-time characteristics: (refer to the following figure.)

- A single physical Server IP address (bond0) that is connected to the Service Network(s) through redundant (Active/Standby Network Interface Teaming) Layer-2 connections. This physical Server IP address establishes the RTP Media Portal Service Instance's presence in the Management-plane through which the service can be managed.
- A single logical MPCP Control IP address (bond0:1) that is associated with bond0 – and so benefits from the configured Active/Standby Network Interface Teaming. This logical MPCP Control IP address represents this RTP Media Portal Service Instance in the Control-plane establishing a point from which the service can advertise its availability – and from which to process service requests.
- One, or two, logical Media IP addresses (bond0:2 and bond0:3) that are also associated with bond0 (and its redundant Layer-2 network connectivity). The Media IP addresses provide points of presence in the Media-plane to which endpoints can direct their media streams for handling by the RTP Media Portal Service Instance.
- A single logical multicast IP address (bond0:4) associated with bond0 and its inherent benefits. The multicast IP address (and port) uniquely identify a Cluster to its members. This multicast IP address represents the Cluster in the Peering-plane and is used by all Cluster members as the

communications channel through which they participate in the Cluster. In the case of a “1+0” Cluster there is only one member active on this channel and so that lone member is effectively operating in a Stand-Alone configuration.

Figure 8 RTP Media Portal Service Instance: Stand-Alone Run-Time

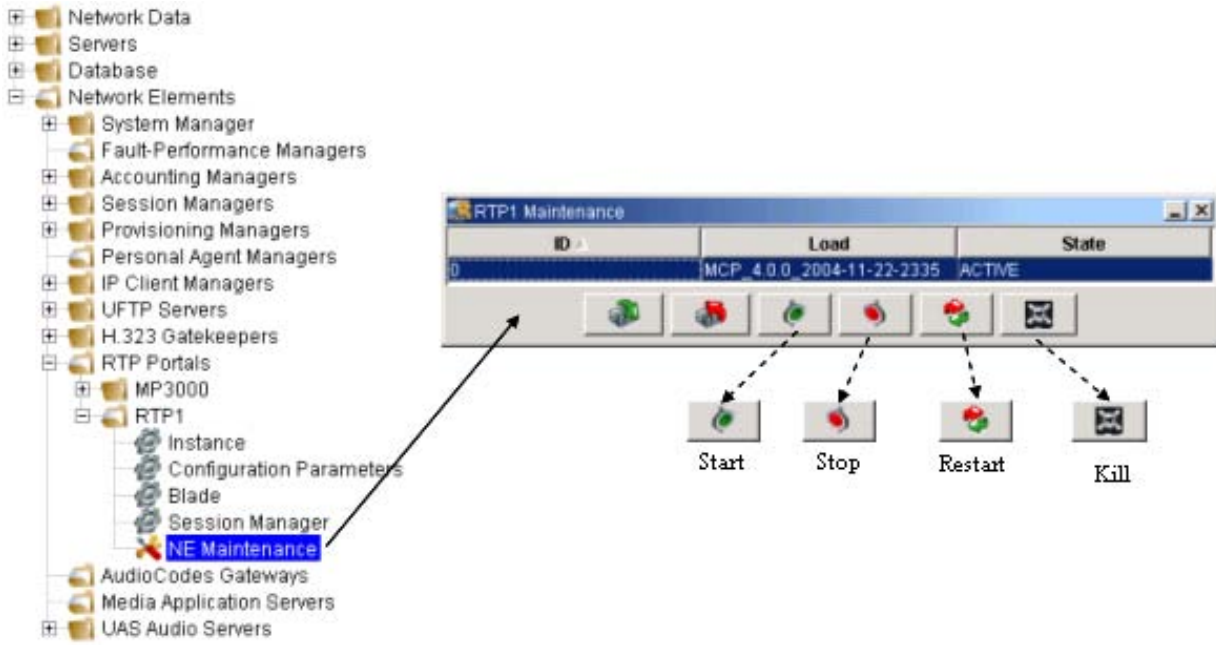


94.6.2.3 Stand-Alone RTP Media Port Management

The Stand-Alone BladeCenter-T RTP Media Portal is managed (telemetry monitoring and state changed) in exactly the same manner used to manage the stand-alone RTP Media Portal components that existed in all previous releases – that is the MCP System Management Console.

Logs, Alarms, and Operational Measurements are viewed in their respective areas of the Management Console.

Likewise, State Management (Start, Stop, Kill commands) continues to be performed through the RTP Portal NE’s Instance window:



94.6.3 RTP Media Portal Service Cluster

94.6.3.1 Service Cluster Instantiation

This section describes the deployment of Service software and the start-up of the RTP Media Portal service for an RTP Media Portal Service Cluster. The deployment phase places the Service software on the target Blade Servers, and the start phase causes the instantiation of run-time structures so that the RTP Media Portal Service Cluster forms and begins to actively provide service.

The RTP Media Portal Service Cluster is an N+1 redundant collection of RTP Media Portal Service Instances. Each instance of the RTP Media Portal Service that runs in the Cluster coordinates its activities with the other member instances. Service coordination takes place over the intra-Cluster communications channel (the Reliable Messaging Framework) that is used to form (using the Election Protocol) and maintain the Cluster (using the Checkpointing functions).

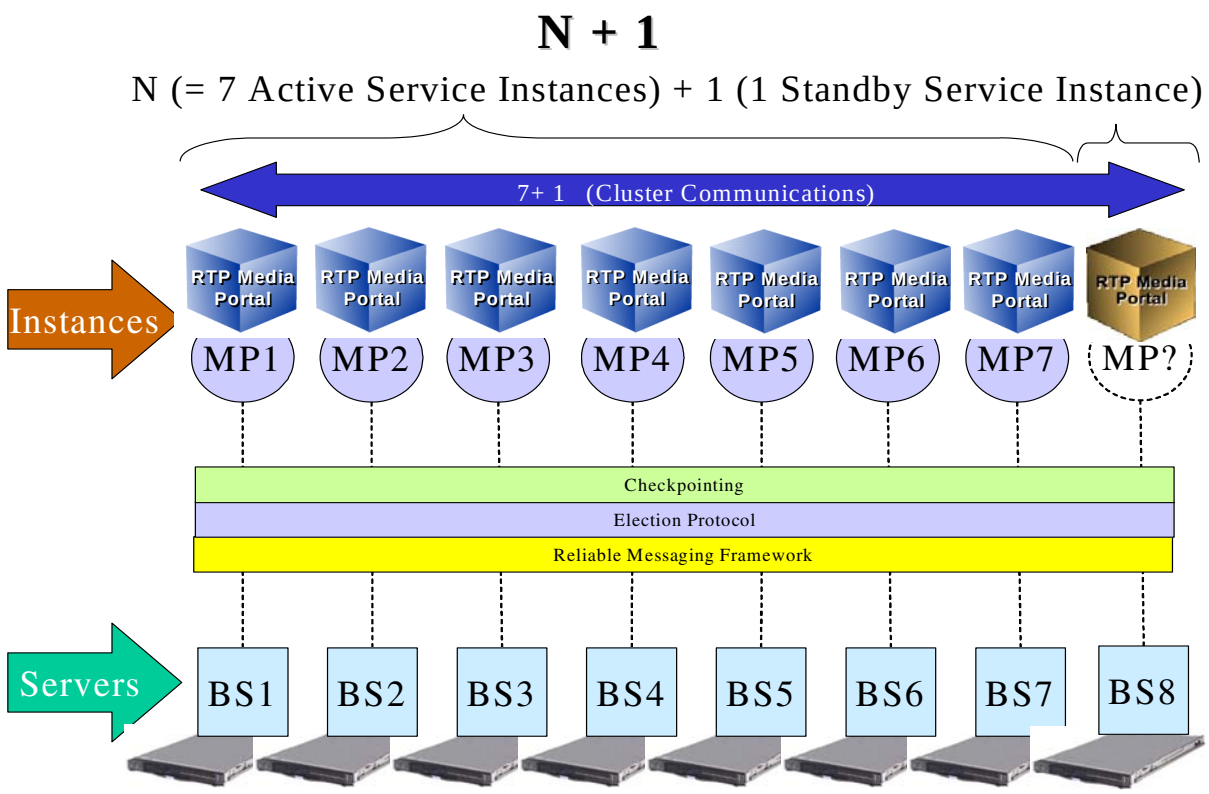
When forming an N+1 Cluster (“N” active instances and “1” standby instance), the lastinstance to join the Cluster becomes the standby instance. This ensures that that a Cluster reaches optimal operational capacity as quickly as possible before electing a standby instance.

The characteristic that distinguishes the configuration of an RTP Media Portal Service Cluster from a Stand-Alone RTP Media Portal Instance is that the Service Cluster is configured with multiple of Service Instance Data elements (in Network Data => Clusters). Once instantiated, any of the RTP Media Portal

Service Instances in the Cluster can be running on any of the Blade Servers participating in the Cluster – ther is NOT a one-to-one relationship..

A single BladeCenter-T chassis can host an RTP Media Portal Service Cluster of up to “7+1”: seven (7) active RTP Media Portal Service Instances and one (1) standby RTP Media Portal Service Instance (refer to the following figure).

Figure 9 RTP Media Portal Service Cluster (Logical View)



The following figures are provided as a reference when performing the next set of numbered steps.

Figure 10 RTP Media Portal Service Cluster Deploy (1 of 2)

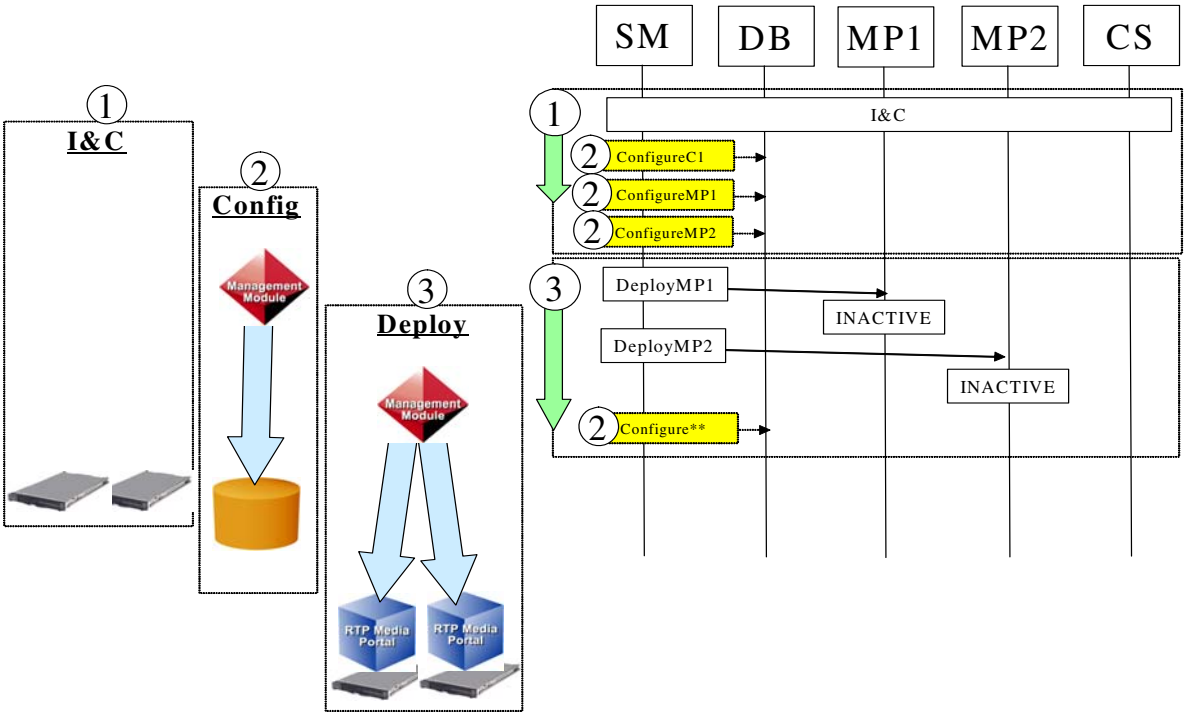


Figure 11 RTP Media Portal Service Cluster Deploy (1 of 2)

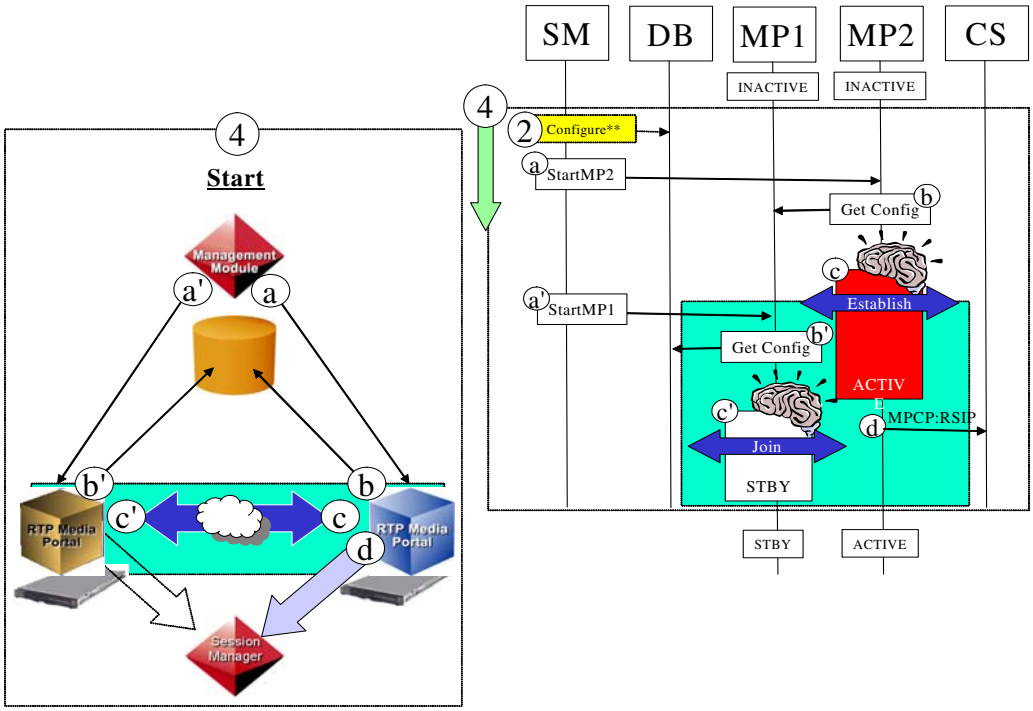
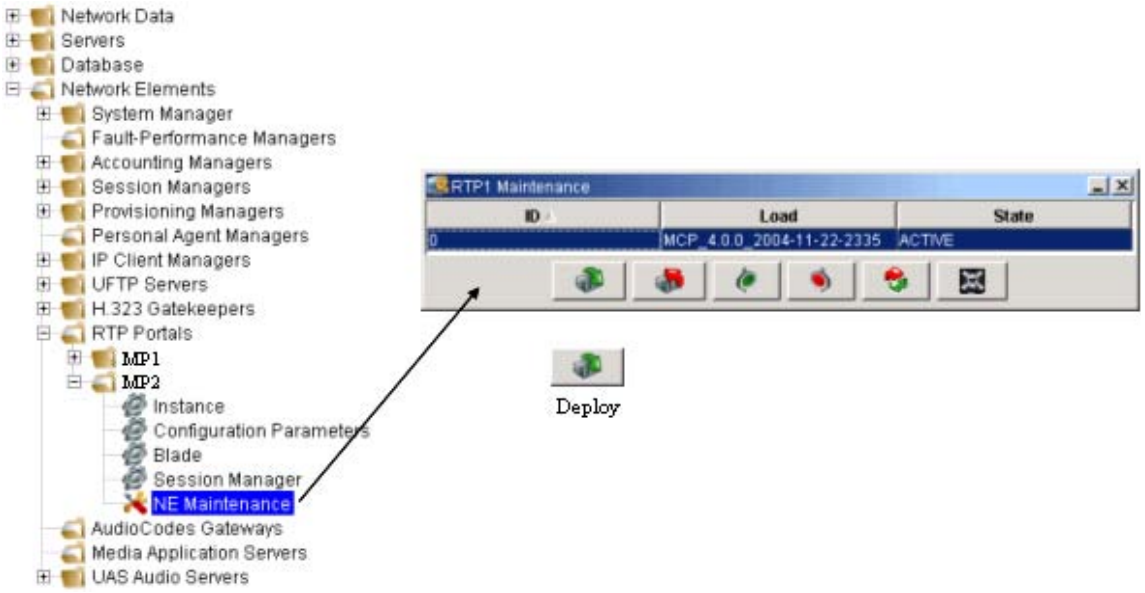
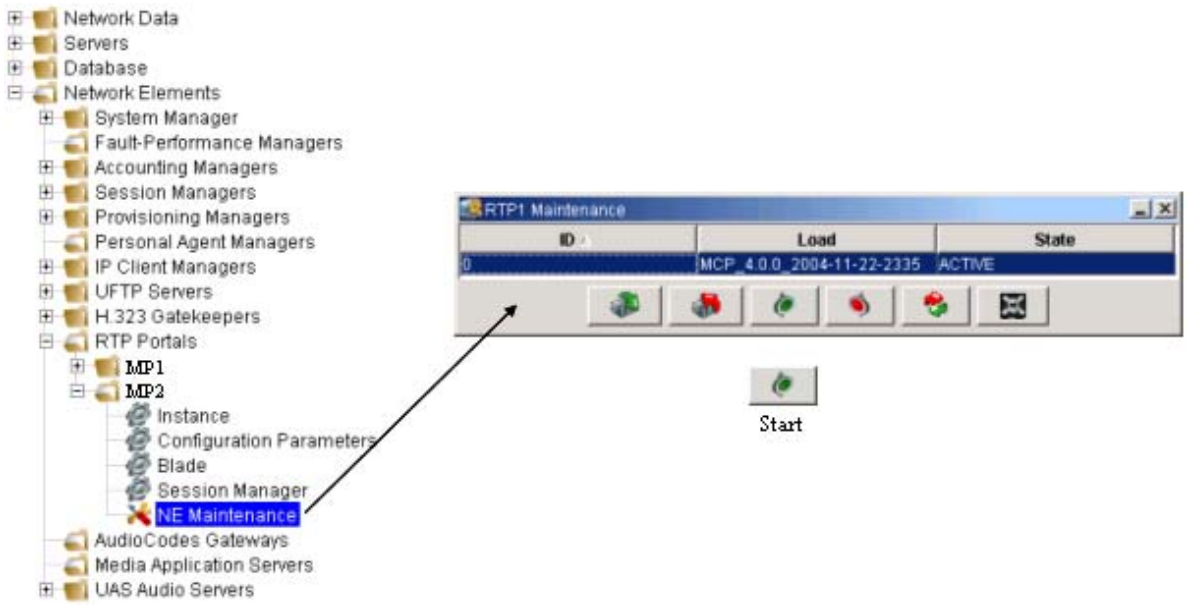


The following activities are performed in the course of introducing a new RTP Media Portal Service Cluster into a site:

1. Installation and Commissioning of the base hardware and software platforms for each of the Blade Servers intended to participate in the Cluster. Refer to “The BladeCenter-T RTP Media Portal Installation and Commissioning Guide”?[1] for detailed information on the installation and commissioning procedure.
2. Configuration of the Service. The RTP Media Portal Service configuration can be changed at any time but (for the most part) is only picked up by the service on start-up. Refer to the “Service Configuration” section of this feature.
3. Navigate the Management Console to the RTP Portal Network Elements representing each of the Blade Servers that will participate in this (“1+1”) Service Cluster. For each of these RTP Portal NEs: open the NE Maintenance window and click the Deploy button to dispatch all Service software to the associated Blade Server:



4. Once successfully deployed the member Service Instances must be started so that instantiation of the run-time structures occurs, the Cluster forms, and the service can be offered. Start-up of the individual Service Instances can occur any time after the service software is deployed to the BladeServers participating in the Cluster. This process is repeated for each of the RTP Portal NEs representing a member of the Cluster:
    a. Once again, navigate the Management Console to the RTP Portal Network Element representing a Blade Server participating in this “1+1” Service Cluster. Open the NE Maintenance window and click the Start button to start-up a RTP Media Portal Service Instance on this Blade Server:



(a' – Issuing Start command to the RTP Portal NE representing the next Cluster participant occurs in a similar fashion)

b. As the RTP Media Portal Service Instance on the target Blade Server begins to come into service it retrieves its configuration data from the MCS Database Server. The RTP Media Portal Service Instance determines that it is configured to participate in a Cluster and then locates the specific Cluster configuration in the Network Data. Instantiation then proceeds using the Cluster Network Data to configure the service.

   (b' – The next RTP Media Portal Service Instance starts-up in a similar fashion)

c. Some of the first processes started by the RTP Media Portal Service Instance are those that support the N+1 Fault Tolerant Framework (i.e. they allocate the configured multicast address and port, start the reliable messaging framework to open the intra-cluster communications channel, etc.). As the N+1 Fault Tolerant Framework Processes come up they establish the Cluster in run-time. Since this is the first RTP Media Portal Service Instance in the "1+1" Cluster it is determined by the N+1 Fault Tolerant Framework to be an active instance.

   (c' – As the second RTP Media Portal Instance starts-up and joins the Cluster, the N+1 Fault Tolerant Framework determines that, since this is configured as a "1+1" Cluster, this instance must be the Standby. The second RTP Media Portal Instance operates in Standby mode –

checkpointing all service data from the active Service Instance and monitoring its status – waiting for the opportunity to assume activity in the event that the active Service Instance encounters a fault)

d. Once a RTP Media Portal Service Instance is set to active state, it issues MPCP RSIP messages to all of its configured Call Controllers (as configured in the Cluster Network Data) in order to advertise its ability to provide service. After this point the Cluster has come into service (not yet at full capacity, but able to provide service) and this RTP Media Portal Service Instance will be called upon to service calls. In the course of processing its service requests, all active RTP Media Portal Service Instances communicate inside the Cluster to checkpoint service data and convey status so that the Cluster remains synchronized and able to survive the failure of one of its members.

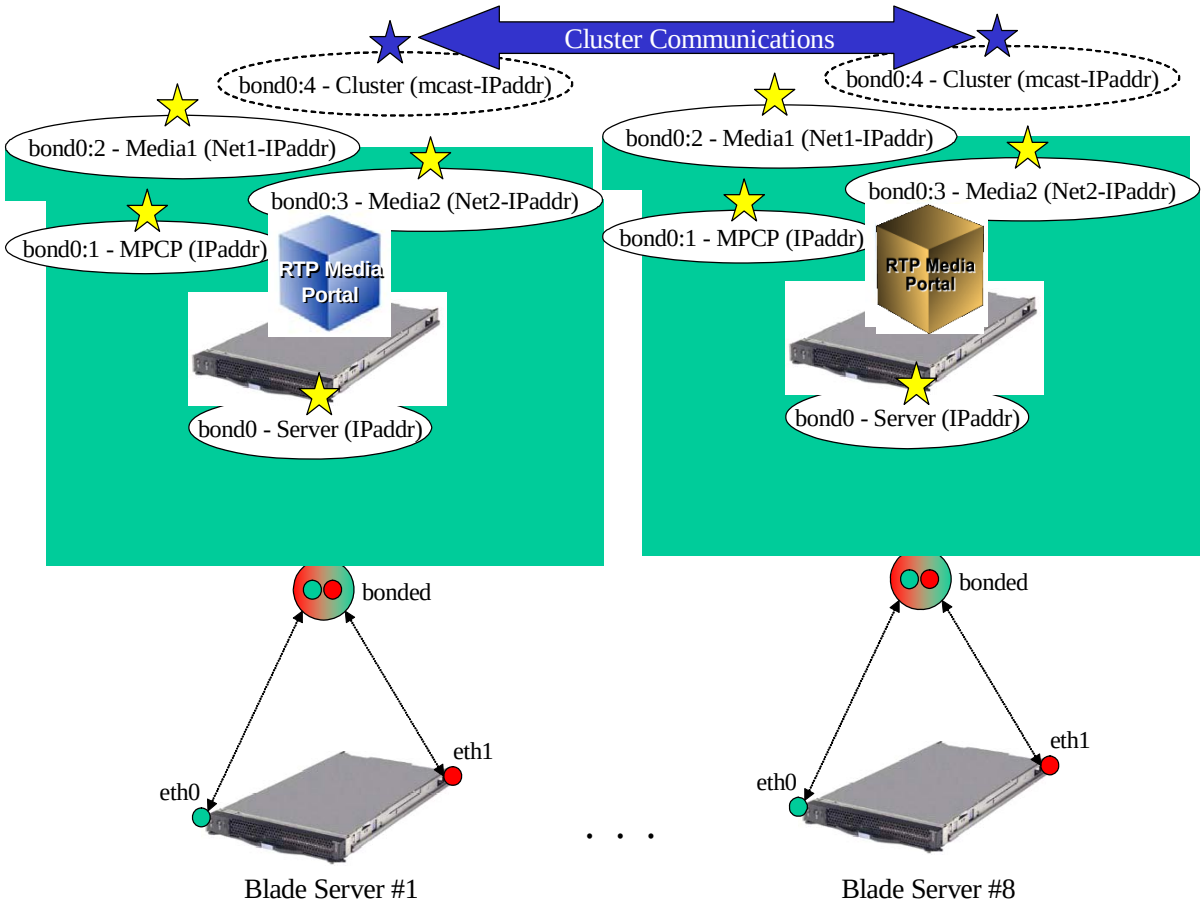
94.6.3.2 Service Cluster Run-Time

Once instantiated, an RTP Media Portal Service Cluster exists as a collection of individual RTP Media Portal Service Instances that communicate with each other (within the Cluster) to checkpoint service data and convey status information. As such the run-time characteristics of the RTP Media Portal Service Cluster is comprised of the run-time characteristics of the member Service Instances. These characteristics are very similar to the Stand-Alone RTP Media Portal Service Instance with the exception of the activity in the Peering-plane: (refer to the figure that follows).

- Each member Service Instance has a single physical Server IP address (bond0) that is connected to the Service Network(s) through redundant (Active/Standby Network Interface Teaming) Layer-2 connections. This physical Server IP address establishes this member RTP Media Portal Service Instance's presence in the Management-plane through which the service can be managed.
- Each member Service Instance has a single logical MPCP Control IP address (bond0:1) that is associated with bond0 – and so benefits from the configured Active/Standby Network Interface Teaming. This logical MPCP Control IP address represents this member RTP Media Portal Service Instance in the Control-plane establishing a point from which the service can advertise its availability – and from which to process service requests.
- Each member Service Instance has one, or two, logical Media IP addresses (bond0:2 and bond0:3) that are also associated with bond0 (and its redundant Layer-2 network connectivity). The Media IP addresses provide points of presence in the Media-plane to which endpoints can direct their media streams for handling by this member RTP Media Portal Service Instance.
- Each member Service Instance in a Service Cluster shares a logical multicast IP address (bond0:4) associated with bond0 and its inherent

benefits. The multicast IP address (and port) uniquely identifies a Cluster to its members. This multicast IP address represents the Cluster in the Peering-plane and is used by all Cluster members as the communications channel through which they participate in the Cluster. In the case of a “1+1” Cluster there is one active RTP Media Portal Service Instance on this channel and and one standby RTP Media Portal Service Instance on this channel. Generally, active Service Instances provide service and convey their service data over the Cluster communications channel to the standby Instance. The standby RTP Media Portal Service Instance checkpoints the service data received from all active Service Instances so that it can effect a transparent take-over of activity for any of the active Service Instances (should the need arise). The standby RTP Media Portal Service Instance also monitors the health of the active Service Instances so that it can take-over activity if a fault is detected on any one of the active Service Instances.

Figure 12 RTP Media Portal Service Cluster Run-Time



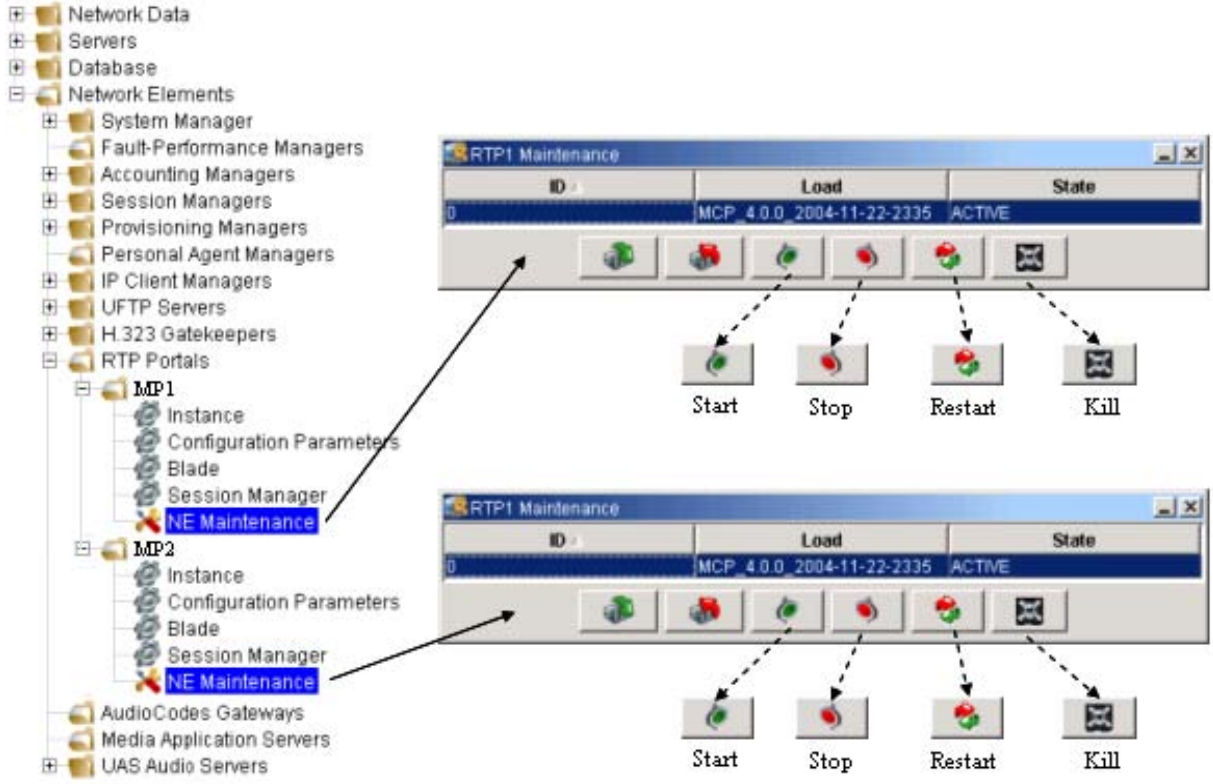
94.6.3.3 RTP Media Portal Service Cluster Management

Unfortunately, there is no capability provided to manage at the Cluster-level. As a result the BladeCenter-T RTP Media Portal Service Cluster is managed (telemetry monitoring and state changed) through administrative coordination of the management of each individual RTP portal NE.

This effectively reduces the management of the RTP Media Portal Service Cluster to the coordinated management of the collection of member RTP Portal NEs through the MCP System Management Console.

Logs, Alarms, and Operational Measurements are available for each member RTP Portal NE and are viewable in their respective areas of the Management Console.

Likewise, State Management (Start, Stop, Kill commands) must be performed in a coordinated fashion on the member RTP Portal NEs in order to achieve the desired operational result. Each member RTP Portal NE is managed using the RTP Portal NE's Instance window:



94.7 Hardware Dependencies

This feature requires IBM BladeCenter-T hardware:

- Chassis.
- DC Power Modules.
- Media Tray.
- Management Modules.
- Blower Modules.
- KVM Module.
- LAN Module.
- IO Modules.
- Blade Servers.

94.8 Software Dependencies

This feature requires Red Hat Linux Advanced Server 3 Linux Operating System.

94.8.1 Network Component Dependencies

This feature requires the collaboration of the following components:

- Management Server (and Management Console): to enable configuration and management through the MCP OAM Framework.
- Database Server: to enable persistence of configuration data and to integrate into the MCP OAM Framework.

94.8.1.1 Nortel Networks Components

Management Server (and Management Console)

The Management Server and the Management Console provide a graphical interface from which to configure and manage the BladeCenter-T RTP Media Portal. In addition to pre-existing functions, the Management Console provides access to the following new structures:

- The new Clusters are created in the Network Data.
- The new Cluster field introduced into the RTP Portal NE Instance Data.

Database Server

The Database Server provides persistent storage and centralized distribution for the newly introduced configuration information related to the BladeCenter-T RTP media Portal:

- Clusters Table (new table)
- RTP Portal Network Entity Table (new Cluster field)

94.8.1.2 Non Nortel Networks Components

Not Applicable.

94.9 Accounting

Pre-existing MCS functionality captured the following information in the accounting stream to identify which RTP Media Portal resources were selected to facilitate a call:

- mediaPortalHost: the RTP Media Portal Host IP address used to facilitate the media path of the call
- origMPConnAddr: The RTP Media Portal Media Blade IP address that replaced the Originator's media connection IP address in the SDP.
- origMPPort: RTP Media Portal Media Blade Port that replaces the Originator's media connection Port in the SDP.
- termMPConnAddr: RTP Media Portal Media Blade connection IP address that replaces the Terminator's media connection IP address in the SDP.
- termMPPort: RTP Media Portal Media Blade Port that replaces the Terminator's media connection Port in the SDP.

This information is still conveyed in the accounting stream but, as a result of this feature, some of the relationships previously implied by this information may no longer exist. Specifically, in previous releases this data not only identified service information – it also uniquely identified a piece of hardware. With the introduction of the RTP Media Portal Service Cluster the service information has been abstracted from the hardware information (a set of Service Instances can be executing on any of the hardware platforms participating in the Cluster at any given point in time) and so there is no longer a precise correlation between service information and hardware information.

94.10 Glossary

Term	Definition
APD	Address and Port Discovery
BPT	Bulk Provisioning Tool
CPU	Central Processing Unit
ERL	Emergency Response Location
FD	Functional Description
FSD	Functional Specification Document
FW	Firewall
IP	Internet Protocol

Term	Definition
MCP	Multimedia Communications Platform
MGCP	Media Gateway Control Protocol
MP	Media Portal
MPCP	Media Proxy Control Protocol (for control of RTP Media Portal)
MPG	Media Portal Group
NAT	Network Address Translation
NAPT	Network Address and/or Port Translation
PSAP	Public Safety Answering Point
PSTN	Public Switched Telephone Network (the legacy circuit-switched telephone network)
RSIP	Restart In Progress (an MPCP message)
RTCP	Real-time Transport Control Protocol
RTP	Real-time Transport Protocol
SIP	Session Initiation Protocol
UDP	User Datagram Protocol

95: Functional Description(FN): A00009711

95.1 Feature name and Feature ID

A00009711 Multimedia Communication Server E911 Caller Hold

95.2 Description

The MCS 3.0 Enhanced 911 feature provided the ability for an MCS originated emergency call to be routed to a local PSAP based on the location of the client device as chosen by the user. It also provided an ANI to the PSAP which could be used to query an ALI database to determine the physical location of the caller. The ANI also provided a callback number to the PSAP in order to allow the PSAP operator to call back the originator of an E911 call.

This feature provides the following enhancements to the MCS E911 service:

1. Denial of originator initiated mid-call features on an E911 call.

2. Terminator call control on an E911 call.

The first enhancement provides the capability to deny the originator of a 911 call the ability to invoke a feature that essentially puts the call on hold. This includes the following features:

- Hold
- Transfer
- Call Park
- Conferencing
- Making a 2nd call from the device (where applicable)
- Receiving incoming requests outside the emergency session

The second enhancement disallows an MCS originator of an E911 call from disconnecting the call. The only party that can disconnect the E911 call is the PSAP.

95.3 Session Manager Behavior

To offer terminator call control and mid-call request denial during an emergency call, the behavior of the Session Manager Emergency service has been modified to perform the actions described in the following sections.

95.3.1 Addition of Resource-Priority Header

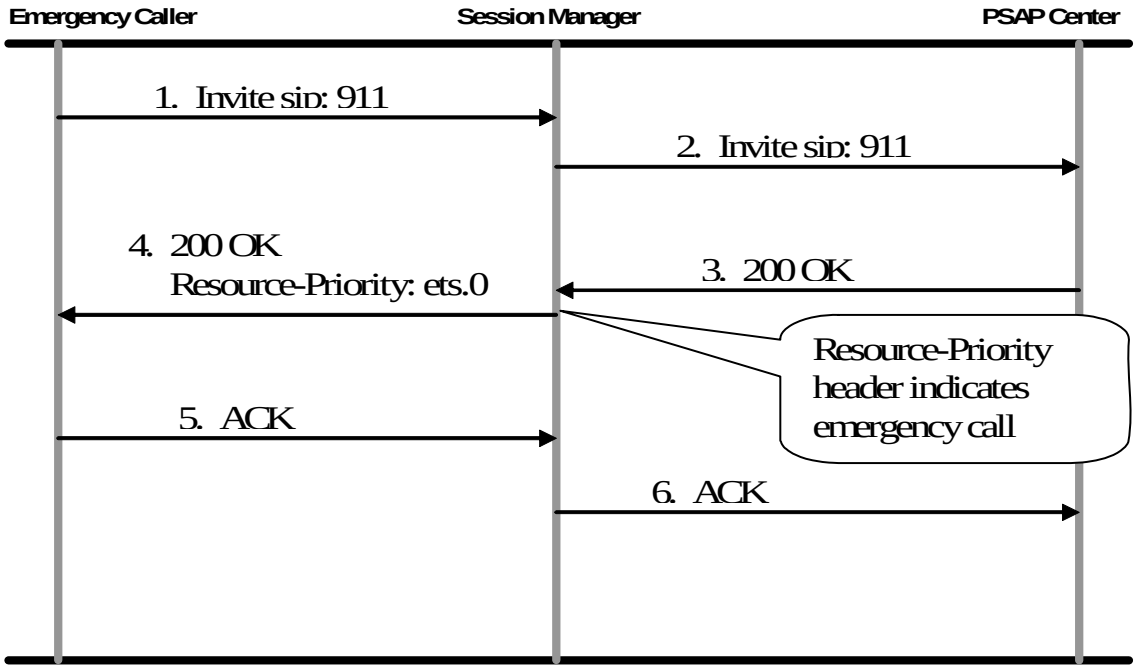
As described in Internet-draft [1], the Resource-priority header may be used to interrupt lower-priority requests at a user terminal, such as an IP phone. Thus, upon discovering that the caller is making an emergency call, the session manager may add a Resource-Priority header to the answer signal (200 OK) during initial call setup signaling. The purpose of the Resource-Priority header in the answer signal is to instruct the caller's device that the call is an emergency call and to set itself in emergency mode. By emergency mode we expect the device to reject any action taken by the user that would interfere with the voice path between the caller and the PSAP operator.

The MCS Session Manager will send a Resource-Priority header in the following format.

```
Resource-Priority: ets.0
```

The namespace ets and priority 0 is used to indicate the call is an emergency call with highest priority, thus instructing the device to handle the current session in emergency mode and to grant high priority to voice services.

Figure 1 Emergency Call Setup



Actions that are expected to be blocked by the emergency caller's device are:

- Terminating the call
- Logging out, Exiting
- Putting the call on hold
- Transfer
- Conferencing
- Receiving/Initiating new calls
- Receiving/Initiating instant messages
- Receiving/Initiating Collaboration
- Codec changes
- Muting the phone

The criteria used by the Session Manager to determine whether a Resource-Priority header is added during the answer setup message is based on a property provisioned at the domain or sub-domain: E-911 Originator Hold.

The Resource-Priority SIP header applies to IADs, gateways, CS2K, and softclients.

95.3.2 Configurable ANI Registration Time

The emergency application on the session manager will be modified to allow a configurable ANI registration time for enterprise Emergency Response Location (ERL). The value is assigned on the provisioning client (refer to Section 95.6.2.1).

95.3.3 Profile Override

The emergency application on the session manager will be modified to allow a direct association between an ERL and a CS2K profile, thereby overriding the profile of the originating subscriber. The profile override is assigned on the provisioning client (refer to Section 95.6.2.2).

95.3.4 Checkpoint Impact

The session manager implements a checkpoint mechanism to achieve fault tolerance[1]. During an enterprise emergency call an ANI is selected from a pool and temporarily associated with the originator. This temporary association is accomplished using the SIP REGISTER method where the expires time is the ANI registration time. Therefore, for enterprise PSAP callbacks to work after failover, the ANI registration times are checkpointed.

Provisioned data, such as the Emergency Response Locations, are synchronized across all session managers using an alternate data-sync (NOTIFY) mechanism.

[1]A00009045 - Call Processing Checkpointing

95.3.5 Mid-Call request denial

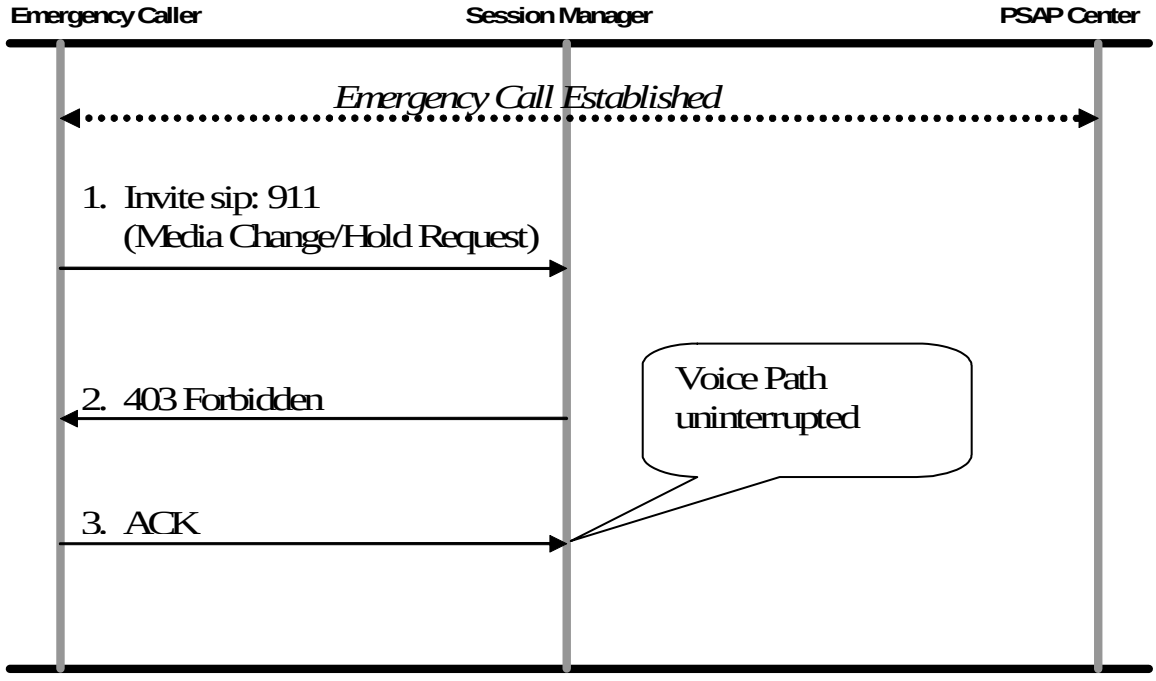
Once an emergency call is established, the session manager will reject all incoming mid-call requests that may affect voice path between the emergency caller and the PSAP operator. Mid-call requests denial applies to all emergency calls independent of the value of the 'Emergency Caller Hold' property. Specific Mid-Call request denial actions taken by the Session Manager are described below.

95.3.5.1 Media changes including Hold requests

Any type of media changes such as putting the call on hold, changing audio settings and adding video will be rejected during an emergency call by the session manager. Media changes initiated with a Re-Invite message will be rejected by the Session manager with a 403 Forbidden error response. The error response is expected to be interpreted as a denial for media change and not as a termination of the media path. While the request for media change and denial is processed, the media path established during call setup must not be interrupted by the caller's device. It is expected that third party devices initiating a mid-call request, do not interrupt media until successful response (200 OK) for media change is received from the Session Manager.

Since most mid-call services (Transfer, Conference, Call Park) start out with a successful hold request, blocking the hold at the session manager will indirectly prevent these mid-call services from being requested.

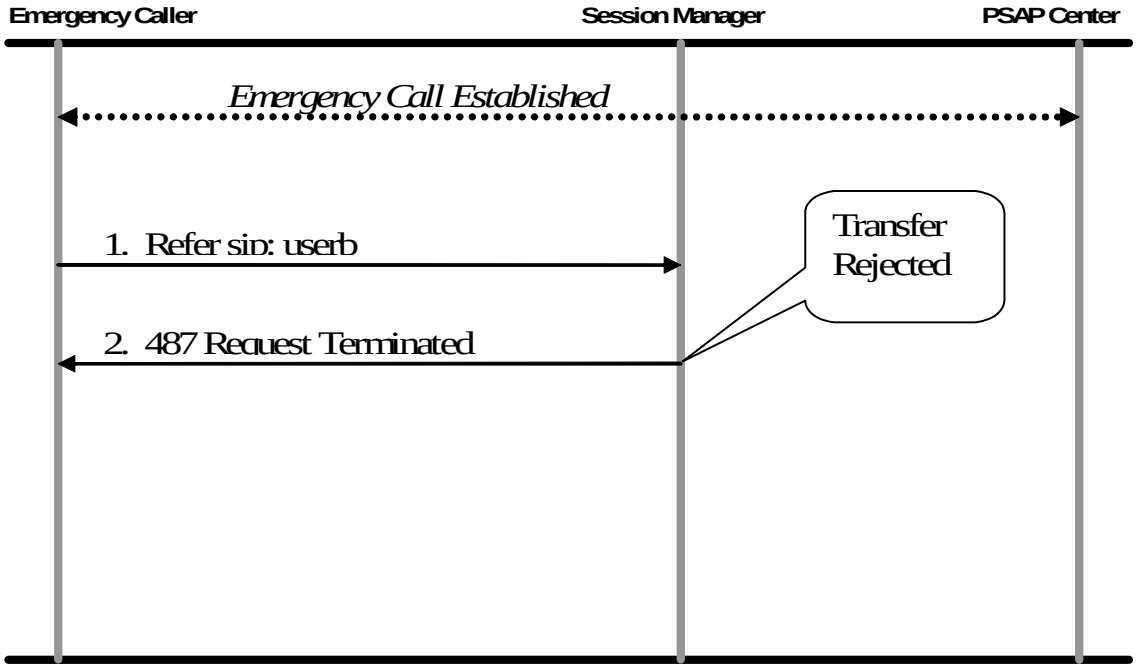
Figure 2 Mid-Call - Media Change Request Denial



95.3.5.2 Transfer

Transferring a call is typically initiated by putting the existing call on hold followed by a REFER message. The session manager will send a 403 in response to the hold request and expect the emergency caller's device to give up on the transfer. However in the event that the device of the emergency caller sends a REFER, the session manager will deny the transfer by failing the transfer request. This is done by sending a “487 Request Terminated” in response to the REFER. The expected client behavior in receiving the 487 would be to revert back to the previous audio stream.

Figure 3 Mid-Call Transfer Request Denial



95.3.5.3 Consultative Transfer and Ad Hoc Conference

Consultative transfers are basically calls where the originator establishes a three-way call by transferring the terminator to a conference server. Typically the caller puts the existing call on hold, then initiates a new call to the conference server and then transfers the existing call on hold to the conference server.

In this scenario, the session manager will block the call hold by sending a 403 response when the emergency caller attempts to put the PSAP operator on hold (similar to Figure 2). It is expected that the emergency caller's device will quit the consultative transfer after receiving the 403 and do not attempt to establish a new call with the conference server.

In the event that the emergency caller's device is non-compliant to the 403 response to the hold and establishes a new call with the conference server, the voice path between the original emergency parties will be broken.

95.3.5.4 New Call

Typically when making a new call while on an active call, the active call is first put on hold and the new call is established. While an emergency call is active the ability to place a new call must be blocked by the emergency caller's device by disabling any New Call controls. However, devices that allow the media hold request signal to be sent to the Session Manager will receive a 403 response (similar to Figure 2). It is expected that the emergency caller's device will quit the consultative transfer after receiving the 403 and do not attempt to establish a new call with the new destination.

In the event that the emergency caller's device is non-compliant to the 403 response to the hold and establishes a new call with the new destination, the voice path between the original emergency parties will be broken.

95.3.6 Emergency Caller Termination

Since RFC 3261 states that clients should stop sending and receiving media just after constructing the BYE (RFC3261-Sec. 15.1.1), the media path between the emergency caller and the PSAP center would be lost if the caller's device allows the user to end the call. Thus enforcing caller hold for emergency call is a feature that must be enforced by third-party clients.

Devices that receive a Resource-Priority header are expected to prevent the user from disconnecting the call by any means. A call may be terminated by putting the handset on-hook, pressing a Hang Up/Release button or closing an Active Call Dialog window of a soft-phone.

However, in the case where the device allows the user to disconnect despite the presence of the Resource-Priority header the session manager will allow the call to disconnect by forwarding the disconnect signaling to PSAP terminator gateway. It is strongly advised that third party devices interacting with MCS are compliant with the Resource-Priority header to avoid undesired emergency call interruptions.

95.3.7 Abnormal Disconnect

Emergency calls that abnormally disconnect should be detected and handled so that emergency resources can deallocate promptly. This feature will introduce a mechanism to detect abnormal disconnects at the session manager for emergency calls.

During an emergency call, an audit (polling) mechanism will transmit a SIP INFO message to the originator at a periodic fixed interval of thirty seconds. In the event that the client does not respond to the INFO request or responds

with an unacceptable response, the audit will fail indicating an abnormal disconnect.

The following INFO responses (from client) are considered unacceptable and will cause an audit failure:

- 404 Not Found
- 408 Request Timeout
- 410 Gone
- 480 Temporarily Unavailable
- 481 Call Leg Transaction Does Not Exist[1]
- 604 Does Not Exist Anywhere

Upon audit failure, the session manager will procede to tear down the call. Accounting records are created each time the audit runs indicating the outcome of the audit.

95.4 SMC Call Control Behavior

When the PC Client is used to originate an E911 call the behavior of the client will change during that call to prevent the originator from disconnecting or initiating new mid-call features. Since the client does not have knowledge of the emergency dial plans, the client will be modified to trigger this feature when the SIP Resource-Priority header is present in the 200 OK.

95.4.1 Call Setup

When a subscriber makes an emergency call, the clients existing behavior is unchanged. That is, the originator may abandon the call while ringing (during call setup), provided the operator has not answered (Figure 4). As part of call setup, the session-manager can signal the client to enable this ‘originator hold’ feature via the Resource-Priority SIP header (Section 95.3.1).

[1]Except when sent from an MCS Session Manager

Figure 4 E911 call window during call setup

95.4.2 Call Established

By default, this feature is disabled in provisioning. In this trivial case, this feature is not activated and the call windows existing behavior applies. The following figure illustrates the non-modal active call window which is common for all calls established on the client.

Figure 5 E911 call window without Originator Hold

95.4.2.1 Originator Hold

When this feature is enabled (provisioned on the originators domain), all buttons on the pop-up window for the emergency call will be disabled and the window cannot be terminated by pressing the “Close” button in the top right corner (Figure 6). The following PCC buttons will be disabled and illustrate a greyscale icon:

- Stop
- Instant Message
- Share
- Hold
- Start Camera
- New Call
- Transfer
- Call
- Send File
- Hang Up
- Mute
- Audio Quality
- Conference

Figure 6 E911 call window with Originator Hold enabled

While the client is in an emergency session, the active call window will become modal (blocking frame with active focus over all other PCC windows). The clients main window (or any other) cannot be accessed until the active call dialog is released. This prevents the originator to shut down by “Login -> Exit” menu.

The emergency call can be disconnected if the process crashes or is killed from the task manager. Within thirty seconds, the session manager will detect the abnormal disconnect and cleanup all resources. After the emergency session

has completed, the client returns to the state it was in prior to the emergency call.

95.4.2.2 DND Behavior

During the E911 call, this feature will transition the client into a mandatory Do-Not-Disturb (DND) mode. This results in rejecting all new inbound requests. Requests subject to being rejected include: new calls, instant messages, collaborations, etc. After the operator disconnects the call, the client will disable this DND behavior.

95.4.2.3 Active Collaboration Behavior

Active collaboration sessions (those created before an emergency call) will be cancelled if the client establishes a call to the emergency operator. Remote participants of the collaboration will observe the cancelled collaboration as if the used had clicked the “Stop” button of the collaboration session window.

95.4.2.4 Client Set Behavior

During the E911 call, the i200x device will behave as described in Section 95.5 “i200x Call Control Behavior”.

95.4.3 SMC Backward Compatability

The complete E911 Originator Hold feature will not be sourced in the 3.x clients. However, 3.x clients can benefit from the ‘mid-call request denial’ (Section 95.3.5) portion of the feature, as this is a network feature. Additionally, limited compatability testing will be performed to ensure the 3.x clients function correctly with the MCS 9.0 Session Manager. For instance, the mid-call reject scenarios should always revert the call back to the PSAP operator.

95.5 i200x Call Control Behavior

When the i200x client is used to originate an E911 call, the behavior of the set will change during that call to prevent the originator from disconnecting the call or initiating mid-call features.

95.5.1 Emergency Call Established

By default provisioning this originator hold feature is disabled. In this case, the clients behavior is not modified. However, if the feature is enabled and an emergency call is established, the device behavior will be modified in the following areas:

1. Do-not-disturb (DND) behavior will be enabled for the life of the call
2. All soft-keys are removed from the LCD display.
3. Subset of keys will not function.
4. Device mode behavior is modified

95.5.1.1 DND Behavior

During the emergency call this feature will temporarily enable DND on the device that is involved in the call. This results in rejecting all new inbound requests. Requests subject to being rejected include: new calls, instant messages, collaborations, etc. After the operator disconnects the call, the device will disable this DND behavior.

95.5.1.2 Soft Key Behavior

During the emergency call this feature will remove all soft-labels from the LCD display, and disable all softkeys. This new behavior prevents the originator from initiating new mid-call features.

95.5.1.3 New Key Behavior

During an emergency call this feature will consume key press events that would normally allow the call to be disconnected. For instance, pressing the 'Release' key or the 'onhook' button (on which the handset usually rests) would typically disconnect the call. The i2004 illustrated in Figure 7 highlights the keys that are impacted. The following keys will be disabled during an E911 call:

- Hold
- Line Keys
- Mute
- Inbox
- Service
- Release
- Soft Keys
- Address Book
- Outbox
- Transfer

Figure 7 i2004 during E911 call with originator hold enabled

95.5.1.4 Device Mode Behavior during Emergency Call

During the emergency call, new behavior will be assigned to the ‘Release’ button and hook-switch button as illustrated in Table 2. Bidirectional transitions between handset mode and speakerphone (or headset) mode are allowed. After the emergency session has completed, the i200x returns to the state it was in prior to the emergency call.

Table 2: i200x Emergency Terminator Call Control Behavior

Emergency call is made using:	Action taken: Handset On-hook (assuming handset was offhook)	Action taken: Release Key Pressed
Handset Mode	The device transitions to speakerphone mode. The call is not disconnected.	No action taken. The call continues in handset mode. The call is not disconnected.
Speakerphone Mode	No action taken. The call continues in speakerphone mode. The call is not disconnected.	No action taken. The call continues in speakerphone mode. The call is not disconnected.
Headset Mode	No action taken. The call continues in headset mode. The call is not disconnected (current behavior).	The device transitions to speakerphone mode. The call is not disconnected.

95.5.1.5 Multi-Line Behavior

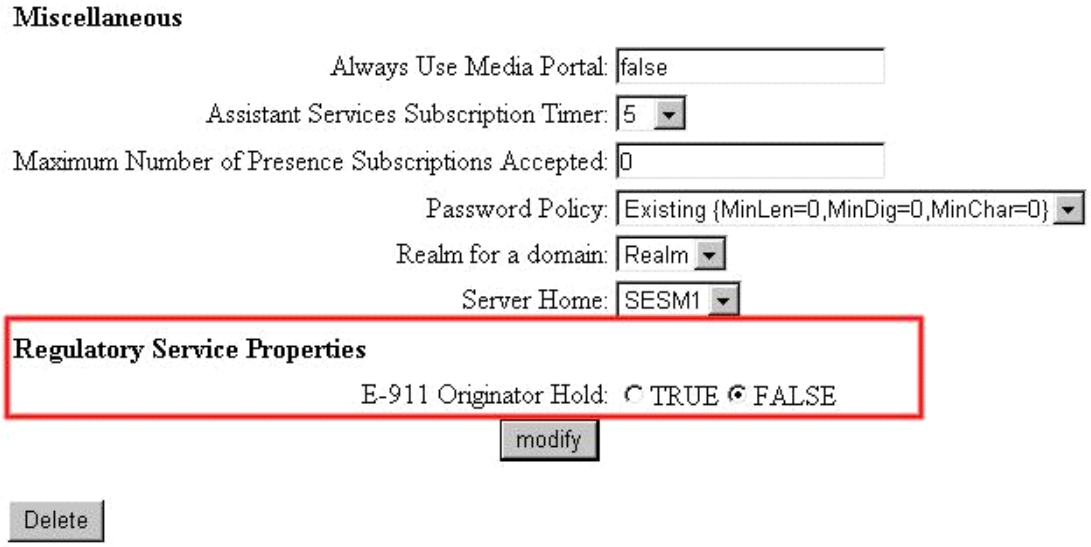
The i200x devices allow for multiple subscribers (6 maximum) to be concurrently logged in to the device. When this feature is enabled, the line that establishes a call to an emergency operator will become active and the remaining lines will be ignored. For instance, inbound calls for any subscriber logged in on the device will not be presented when an emergency call is active.

95.6 Provisioning Client Behavior

95.6.1 Domain Configuration

The E911 Originator Hold feature will be provisioned as a boolean (sub) domain parameter. Provisioning the service option against the domain allows the feature to be enabled on inbound 911 calls from non-registered routes, for instance a PRI gateway. The default value of this parameter will be false indicating that the feature is disabled. The figure below illustrates this domain parameter.

Figure 8 E911 Originator Hold domain parameter

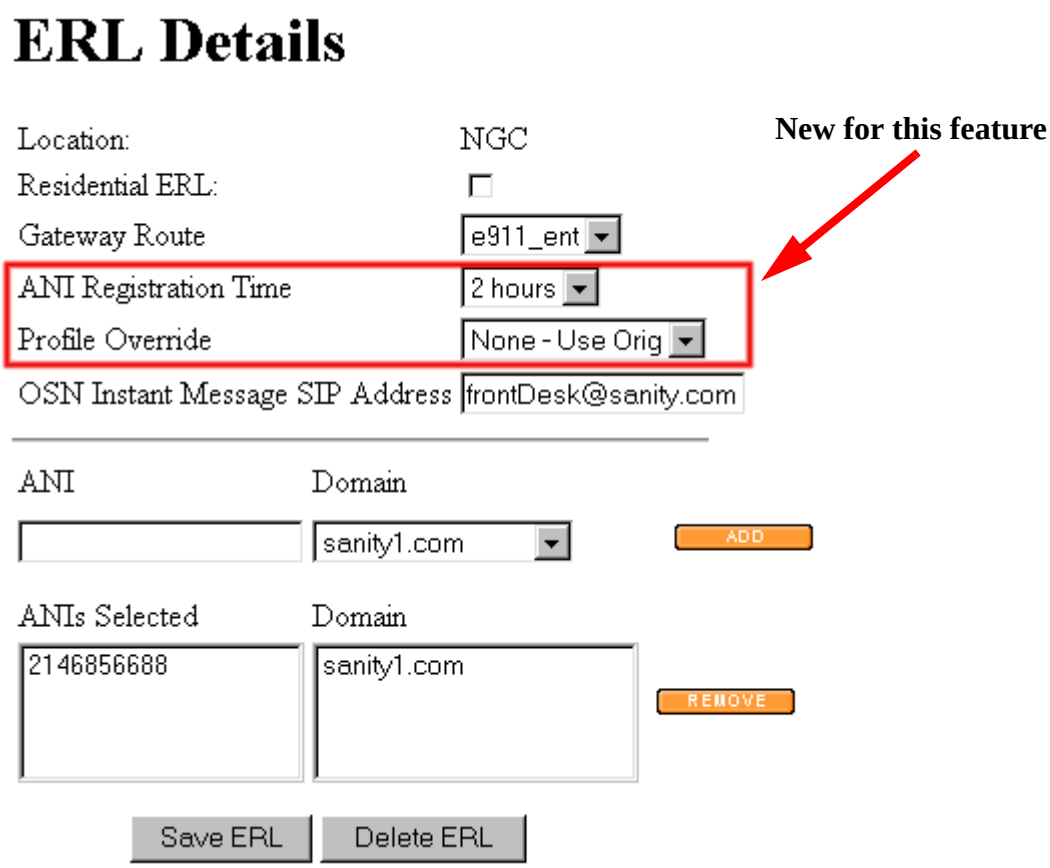


The parameter configuration at the sub-domain will have higher precedence over the configuration at the root domain.

95.6.2 ERL Configuration

The Emergency Response Location provisioning will be modified by this feature to include a customizable ANI Registration time and a Profile Override.

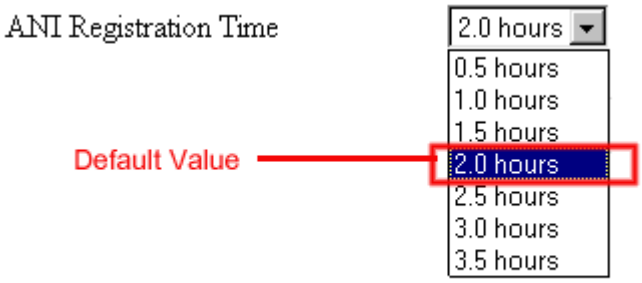
Figure 9 ERL Provisioning



95.6.2.1 ANI Registration Time

This parameter allows the domain administrator to configure the amount of time a enterprise callback number is bound to the originating E911 subscriber. Previously, this value was fixed at 2 hours. The dropdown will allow the administrator to select a value from a list as shown in Figure 10 .

Figure 10 Ani Registration Time

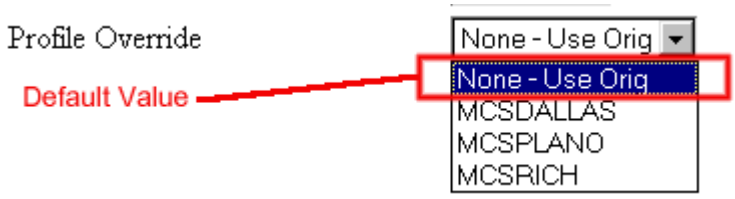


The ANI registration time applies only to enterprise ERLs.

95.6.2.2 Profile Override

This parameter allows the administrator to associate a CS2K profile to an ERL location. This simplifies routing on the MCS session manager[1] by not using telephony translations to override the profile. The dropdown will display all CS2K profiles available in the root domain and all sub-domains, as well as the default value of 'None - Use Orig' as shown in Figure 11 .

Figure 11 Profile Overide



The profile override parameter applies only when routing to CS2K gateway routes that require a different profile. For example, routing to a CS2K that has connectivity to multiple PSAP jurisdictions.

The default value of 'None- Use Orig' should be used to continue using the profile of the originating subscribers (sub)domain. That is, no static association between the ERL location and the profile.

95.6.3 Open Provisioning Interface

The open provisioning interface allows third-party applications to invoke methods on the remote MCS provisioning server. This feature will add two new attibutes to the ErlInfo provisioning entity:

- ANI_REG_TIME
- PROFILE_OVERRIDE

Additionally, a new OPI exposed method will be added under "Domain Profile Operations" to allow a client to retrieve a list of profiles under a given root domain. An OPI client would invoke this method prior to adding or modifing the ERL(s).

String[]::getAllDomainProfiles(String::domainName)

95.7 Hardware Requirements or Dependencies

Not Applicable.

[1]Q00902906 : E911 calls can complete to wrong E911 PSAP

95.8 Software Requirements or Dependencies

Not Applicable.

95.9 Limitations and restrictions

1. The behaviors introduced by this feature are limited to the MCS clients, and may not work with third party SIP clients or legacy clients not compliant with the Resource-Priority header.
2. MCS clients compliant are SMC 4.0, SMC 9.0 and IPCM 9.0.
3. Unable to establish a three way call with an emergency number.
4. During an emergency call the operator will not hear a tone when the originator attempts to disconnect the call.
5. Protocols implementing a single stage release (e.g. H323 protocol) will not be able prevent the originator from disconnecting the call.
6. Emergency calls from foreign domains, including other MCS systems, are not supported.
7. Emergency calls initiated using Click-To-Call will not complete when the Session Manager is in overload.
8. Blind transfer to an emergency number are not allowed.
9. All limitations and restrictions documented in [3] (“MCS3.0 E911 Enhanced 911”) also apply to this feature.

95.10 Compliance Statement

This feature introduces a partial implementation of the Resource-Priority SIP header as documented in draft-ietf-sip-resource-priority-05 [2].

The documented intention of the Resource-Priority header is to request a level of priority when allocating resources (by including the Resource-Priority header in a SIP Request message). The MCS intention of the Resource-Priority header is to add a Resource-Priority header in the 200 OK response message to indicate the User Agent Client that the call is an emergency call and that a certain level of priority has been granted.

The MCS session manager does not implement request behavior relating the Resource-Priority SIP header as described in [2].

95.11 Interactions

95.11.1 Call Park

Call Park is service supported only with MCS core clients. Thus the Call Park service is disabled in emergency calls by disabling Call Park controls from MCS clients during emergency calls.

95.11.2 Assistant / Assisted User

95.11.2.1 Assistant calls 911

In the event the assistant calls an emergency number and establishes a call to the PSAP operator, the clients will exhibit modified behavior to minimize interruptions to the emergency call.

The assistant console will continue to be updated with presence information of the assisted users. However, the context menu will disallow any new call or session from being initiated from the assistant console during that call.

When an assisted user parks a call while an assistant is on a 911 call, the assistant will *not* be presented with this parked call. After the emergency call is completed, the assistant would need to logout and login again to receive the notification of the parked calls. The assisted user can retrieve the parked call at any time. The purpose is to prevent any distractions while the client is engaged in an emergency call.

95.11.2.2 Assisted User calls 911

The emergency call from an assisted user behaves in the same manner as previously describer in the client sections (Section 95.4 for SMC or Section 95.5 for i200x Device).

95.11.3 Click-to-Call

Click-To-Call calls are made either by: directly by logging in to the Personal Agent (PA) from the Click-To-Call page or indirectly by initiating a call form a SMC in converged mode.

Click-To-Call calls work by having the PA establish a call with the originator and then transferring the originator to the terminator. Added complexity is introduced depending on whether the originating user is hosted by a CS2K device.

Emergency calls attempted via Click-To-Call will be established. However limited caller hold feature support is provided. Detailed scenario behavior is presented in the following sections.

Warning: It is not recommended to place emergency calls using Click-To-Call for the following reasons:

- The selected emergency location is determined by the location provisioned in the user screen of the Provisioning Client and not the location selected during login / registration.
- The emergency numbers dial plan and translations may not be synchronized between the PAD's switch and MCS.
- The E911 caller hold feature is not enforced on all Click-To-Call scenarios.

95.11.3.1 PA Click-To-Call; Orig: Sip User, Term: emergency number

This scenario works as long as the subscriber originating the call is located at Provisioning Client User location. The Sip User's client will receive the Resource-Priority header and should be able to disable all mid-call and terminating controls.

95.11.3.2 PA Click-To-Call; Orig: emergency number (hosted by CS2K), Term: Sip User

In this scenario the Emergency center is called first and then transferred to the Sip User. The Emergency center operator will answer the call and hear ringback until the Sip User Answers the call. If the terminator does not answer the call, the operator will hear ringback until the answer timer expires.

However, if the Click-To-Call call is established, the caller hold feature would not be enforced by the terminator's device. Mid-call requests will be rejected by the session manager.

95.11.3.3 PA Click-To-Call; Orig: emergency number (not hosted by CS2K), Term: Sip User

In this scenario the Emergency center is called first and then transferred to the Sip User. The Emergency center operator will answer the call and hear ringback until the Sip User Answers the call. If the terminator does not answer the call, the operator will hear ringback until the answer timer expires.

However, if the Click-To-Call call is established, the caller hold feature would not be enforced by the terminator's device. Mid-call requests will not be rejected by the session manager.

95.11.4 Converged Desktop Calls

95.11.4.1 Emergency Call originated from PAD

In this scenario the subscriber is dialing the emergency number directly from the Preferred Audio Device (PAD). The device hosting the PAD may be engineered to route emergency calls directly or through the MCS Session Manager.

When the call is routed directly by the PAD's hosting switch the emergency call will follow the PAD's switch emergency call policy.

When the call is routed via the MCS, the MCS session Manager will send the Resource-Priority header back to the switch hosting the PAD in the 200 OK. The PAD's switch must implement the Resource-Priority Header in order to prevent caller disconnect. Mid-call requests will be rejected by MCS Session Manager with a 403 error response.

95.11.4.2 PA Click-To-Call; Orig: 911 (hosted by CS2K) , Term: Converged Desktop User

In this scenario the Emergency center is called first and then transferred to the Sip User. The emergency center operator will answer the call and hear ringback until the Sip User Answers the call. If the terminator does not answer the call, the operator will hear ringback until the answer timer expires.

If the Click-To-Call call is established, the CD user will be allowed to terminate the call. Mid-call requests will be rejected by the session manager.

95.11.4.3 PA Click-To-Call; Orig: 911 (not hosted by CS2K) , Term: Converged Desktop User

In this scenario the Emergency center is called first and then transferred to the Sip User. The emergency center operator will answer the call and hear ringback until the Sip User Answers the call. If the terminator does not answer the call, the operator will hear ringback until the answer timer expires.

If the Click-To-Call call is established, the CD user will be allowed to terminate the call. Mid-call requests will not be rejected by the session manager.

95.11.4.4 PA Click-To-Call; Orig: Converged Desktop User with PAD hosted by CS2K, Term: 911

In this scenario the subscriber PAD device is called first and then transferred to the emergency center.

After the Click-To-Call call is established, the CD user will be allowed to terminate the call, but mid-call requests will be rejected by the session manager.

95.11.4.5 PA Click-To-Call; Orig: Converged Desktop User (not hosted by CS2K), Term: 911

In this scenario the subscriber PAD device is called first and then transferred to the emergency center.

It is assumed that the switch hosting the PAD is engineered to route the emergency call directly, thus following the PAD's switch emergency call policy.

95.11.4.6 Emergency Call originated from SMC Converged Client

Same behavior as Personal Agent Click-To-Call. See Section 95.11.4.4 and Section 95.11.4.5.

95.11.5 Call Pickup

Emergency Enterprise callbacks to a subscriber belonging to a Call Pickup group will not be routed to the call pickup terminal. Call Pickup terminal routing is driven by CPL routes which are disabled during emergency enterprise callbacks.

95.12 Glossary

Term	Description
MCS	Multimedia Communication Server
SMC	Personal Communication Client
PAD	Preferred Audio Device
PA	Personal Agent

2. Communications Resource Priority for the Session Initiation Protocol (http://www.ietf.org/internet-drafts/draft-ietf-sip-resource-priority-05.txt)
3. MCS3.0 FTR307 Enhanced 911 Feature Description

96: Functional Description(FN): A00009726

96.1 Feature name and Feature ID

A00009726, Addition of CALIX_C7 Gateway certificate

96.2 Purpose

In SN09, the gateway certificate/profile “CALIX_C7” is created in order to provision the Calix C7 H.248 large line gateways in SESM. The Calix C7 gateway will support up to 1023 endpoints (POTS lines) per VMG.

This MG is being introduced under ICAF A00009726. The SESM provisioning code was submitted as part of activity A00011746. That feature was introduced to set the LGRP type in the certificate.

96.3 Customer Facing Document Changes

After the code changes, when associating a media gateway using SESM GUI, in the “Gateway Profile Name” pull down list, the following new profile name in addition to the existing profiles will show up as a selection choice.

CALIX_C7

The characteristics of the above gateway are listed in the following table.

GW Profile Name	GW Category	Signal Protocol	Protocol Version	Protocol Port	Service Type	Port/EP Capacity	GWC Profile No.
CALIX_C7	Large	MEGACO(4)	1.0	2944	Line	1023	74

When creating an OSSGATE input XML file for associating a “CALIX_C7” gateway, please reference the above table for values of the tags <mgProfileName>, <mgProtocolType>, <mgProtocolVersion>, and <mgProtocolPort>.

96.4 Related Documentation

GWProfile LGRP_Type (A00011746).doc

The above feature was done in support of assigning a specific LGRP type to a gateway based on the content of the certificate as part of MG association.

97: Functional Description (FN): A00009777

97.1 Feature name and Feature ID

A00009777 - IEMS Mediant 2000 Integration

97.2 Description

IEMS serves as an integrated platform for managing various devices. This document lists the changes that are required in IEMS in order to manage the new device MG 3200 (Network Element).

IEMS will handle the Fault and Performance Management for this new device through SNMP interface.

97.2.1 Acronyms used

NE - Network Element

OID – Object Identifier

MS2000 - Media Server 2000

MG 3200 - Media Gateway 3200

EMS - Element Management System

MIB – Management Information Base

IEMS - Integrated Element Management Systems

SNMP - Standard Network Management Protocol

HTTPS - Secure Hypertext Transfer Protocol

97.2.2 MG 3200 Provisioning

The MG 3200 Network Element can be added using Tools--> Add--> EMS / NE menu. In the initial screen, the "IP Address" field represents the IP of the MG 3200 device to be added, "Type" represents whether it is a EMS or NE (in our case it is "NE"), "Device Type" represents the name of the device to be added (in our case it is "MG 3200"), "Device Version" represents the version of device (in our case it is "9.0") to be added and the "Web Username and Web Password" are the username and password that are needed for the configuration tool.

The subsequent screens gets all the necessary SNMP interface details that are needed for fault and performance. IEMS supports only SNMP "v1" and "v2c" versions of MG 3200 not of "v3" version.

97.2.3 Automatic INI File Backup

MG 3200 has the IPSec configurations stored in a INI file named BOARD.ini, this file will change based on IPSec Configuration changes. IEMS will be taking a backup of this file at regular intervals (configurable) and store it for future use.

IEMS will have the following abilities with respect to the MG 3200 INI Backup functionality,

IEMS will be using HTTPS to communicate and retrieve the INI Files from the MG 3200 device. The design of the HTTPS communication will be by creating an URLConnection with the specified HTTPS URL and establishing a connection. The Authentication will be
taken care by using the appropriate Headers in the URLConnection (basic and digest authentication).

The Right Click Menu on the MG 3200 will have a new menu item to Configure INI Backup . This will popup the INI Configuration dialog similar to that of a MS 2000 device. This screen will have the provision to configure the INI Backup to occur daily or a weekly basis and at a particular time.

A successful configuration will initiate and schedule the next back up time using the timer scheduler. In the design part IEMS will mostly be using the MS 2000 code for scheduling and the GUI pop up. IEMS will write new code to handle the HTTPS communication, Certificate Handling and Authentication for MG 3200 INI Backup. The following will give a clear picture and what can be done and not done:

- IEMS will be using the following URL to retrieve the INI File - https://<mg3200 ip>/FS/BOARD.ini
- The web username and web password given while datafilling the MG3200 device in to IEMS will be used for Authentication.
- Thus retrieve INI files will be stored in the /data/loads/audiocodes/<mg3200 ip>/<current time>.Board.ini If the file is encoded in the device, the IEMS backup will retrieve and store it in the same way. Please refer Appendix 3 for INI encoding details.
- IEMS will trigger the INI Backup based on earlier configurations during a warmstart of the IEMS.
- IEMS will not push this file to the SDM as it is the case in MS2000

- Configuration of INI back up can be done to all the MG3200 devices configured on the IEMS and not for a single MG3200. And you can schedule it and cannot execute it immediately.

97.2.4 IPSec and IKE Configuration

This feature adds IPSec and IKE configuration capabilities to the MG 3200 node configuration tool. This will allow the craftsperson to enable IPSec for secure messaging between the IEMS and MG 3200 as well as configure the IPSec and IKE parameters necessary for the MG 3200 to securely send and receive messages.

A menu "IPSec and IKE Config Tool" will be available on the right click of the MG 3200 Map Symbol. On clicking this menu, IEMS opens a panel over which the IPSec Configuration frame is embedded.

Refer to the document IPSecFN_CN.pdf for "Add IKE and IPSec parameters to the MG 3200 for IEMS MG 3200 secure messaging."

98: Functional Description (FN): A00009822

98.1 Feature name and Feature ID

A00009822 - General Security Log When the User Logs Out

98.2 Description

The Client Session Monitor tracks and records the authentication's, client starts and client stops of the users within the system. For SN09, those applications which begin reporting client start and stops are MG9kEM and CS2M.

The Client Session Monitor allows the end security user to view reports that display which client application sessions are currently active and for what user. It will also provide the reporting ability to view historical data regarding client application usage by user, date or device. The historical data includes start and end times of client sessions, source ip, destination ip, application name and reason for the session end.

The Client Session Monitor also provides interfaces for the clients to retrieve the last time a given user successfully authenticated against the system. This feature modifies the common launch page to display this last successful authentication time - as well as the sspfs LoginAuthentication GUIs.

The Client Session Monitor Reporting Utility is launchable via the IEMS client as well as direct URL or a cli interface provided on the server.

98.3 Hardware Requirements or Dependencies

This feature is available only on IEMS Central SS systems.

98.4 Software Requirements or Dependencies

SN09 IEMS Central SS software
Oracle

98.5 Limitations and restrictions

Only successful user initiated authentications which are authenticated via the IEMS SS are recorded. Any authentication which is performed locally will not be recorded in the Client Session Monitor.

In the case where a client session appears to still be active via the report - but the security user knows the session to no longer be active - the security user can mark that session as completed. Marking a session as completed will not cause any actions outside the realm of this report. It will simply update the

session activity in the database - it will not force a user off - end their session - etc. If a user is still active and their session is marked completed, when the user truly ends the session - the row will be updated with that action's end time.

98.6 Interactions

None

98.7 Glossary

Term	Description
CS2M	Call Server 2000 Manager
IEMS	Integrated Element Manager Server
IEMS Central SS	IEMS Central Security Server
MG9kEM	Media Gateway 9000 Element Manager

99: Functional Description (FN): A00009823

99.1 Feature name and Feature ID

A00009823 - Security Logging for SSPFS

99.2 Description

This feature adds security logging to the SSPFS CLI scripts. Security logs are to be generated whenever any security affecting parameter is changed from the CLI.

In the event that a hacker or user were to change a security parameter using the CLI, a discrete entry will be written to the security log. Each security log will contain a description of the action, an action identifier, the identity of the user, source address of the user, and the date and time that the action occurred.

99.2.1 Security Log location

The Security Log file is stored at:

/var/log/securitylog

99.2.2 Affected CLI Scripts

99.2.2.1 Login Retries Limit

SSPFS CLI will log whenever an MSAP access threshold is changed. CLI 2-14-6; Login Retries Limit in login_timeout.ksh.

99.2.2.1.1 Security Log output

Feb 22 16:36:31 wnc0y0nr PROG=login_timeout.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=login_timeout.ksh MESSAGE="Setting Retries Limit = 3"

99.2.2.2 Login Session (User Inactivity) Timeout

SSPFS CLI will log whenever an MSAP time interval that controls keyboard lockout is changed. CLI 2-14-1; Login Session (User Inactivity) Timeout configuration in login_timeout.ksh.

99.2.2.2.1 Security Log output

Feb 22 16:33:05 wnc0y0nr PROG=login_timeout.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=login_timeout.ksh MESSAGE="Setting Login Session Timeout = 1440"

99.2.2.3 User Termination Timeout

SSPFS CLI will log whenever an MSAP time interval that controls keyboard lockout is changed. CLI 2-14-2; User Termination Timeout configuration in login_timeout.ksh.

99.2.2.3.1 Security Log output

Feb 22 16:33:28 wnc0y0nr PROG=login_timeout.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=login_timeout.ksh MESSAGE="Setting Login Session Termination Timeout = 1440"

99.2.2.4 User Reauthentication Disable Timeout

SSPFS CLI will log whenever an MSAP time interval that controls keyboard lockout is changed. CLI 2-14-3; User Reauthentication Disable Timeout configuration in login_timeout.ksh.

99.2.2.4.1 Security Log output

Feb 22 16:33:44 wnc0y0nr PROG=login_timeout.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=login_timeout.ksh MESSAGE="Setting Login Session Reauthentication Disable Timeout = 30"

99.2.2.5 Login Session Master Server

SSPFS CLI will log whenever an MSAP time interval that controls keyboard lockout is changed. CLI 2-14-4; Login Session Master Server configuration in login_timeout.ksh.

99.2.2.5.1 Security Log output

Feb 22 16:34:14 wnc0y0nr PROG=login_timeout.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=login_timeout.ksh MESSAGE="Setting Login Session Master Server = test"

99.2.2.6 Socks Security Service

SSPFS CLI will log whenever changes to MSAP security profiles and attributes occurs. CLI 2-13-1-1; Socks Security Service configuration in configureSocksPorts.sh.

99.2.2.6.1 Security Log output

Feb 22 16:41:08 wnc0y0nr PROG=configureSocksPorts.sh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=configureSocksPorts.sh MESSAGE="Setting Socks Server port = 10080"

Feb 22 16:41:12 wnc0y0nr PROG=configureSocksPorts.sh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=configureSocksPorts.sh MESSAGE="Setting Socks Client port = 10090"

99.2.2.7 IEMS Server IP Address

SSPFS CLI will log whenever changes to MSAP security profiles and attributes occurs. CLI 2-13-1-1; IEMS Server IP address configuration in chg_iems_ip.ksh.

99.2.2.7.1 Security Log output

Feb 22 16:42:09 wnc0y0nr PROG=chg_iems_ip.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=chg_iems_ip.ksh MESSAGE="Setting IEMS Server IP Address = 4.4.4.4, Domain Name = wnc0y0nr"

99.2.2.8 Default PAM

SSPFS cli will log whenever changes to the MSAP security configuration (e.g., routing to a security server) occurs. CLI 2-13-3-1-1; Default PAM configuration in pam_switch.ksh.

99.2.2.8.1 Security Log output

Feb 22 16:45:12 wnc0y0nr PROG=pam_switch.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=pam_switch.ksh MESSAGE="Setting Default PAM Configuration"

99.2.2.9 Radius PAM

SSPFS cli will log whenever changes to the MSAP security configuration (e.g., routing to a security server) occurs. CLI 2-13-3-1-2; Radius PAM configuration in pam_switch.ksh.

99.2.2.9.1 Security Log output

Feb 22 16:46:25 wnc0y0nr PROG=pam_switch.ksh SRC.USR=root SRC=wnc0y0nr STAT=Success EVNT.TYPE=USER_ACT_EMS_Prov CMD=pam_switch.ksh MESSAGE="Setting PAM Radius Parms: Radius Client Timeout = 12, SAML Connection Timeout = 20, SAML Request Timeout = 10"

99.6 Interactions

Not applicable.

100: Functional Description (FN): A00009828

100.1 Feature name and Feature ID

A00009828 - Granular Service Packaging

100.2 Background

Curretly services like Instant Messaging, Client Collaboration features like webpush, filetransfer, whiteboard, transfer clipboard, Etherset support for 1220x phone etc. are part of the basic services and are not service package controlled. There was no way to limit the availability of these services to the end users on a per domain/user basis. The objective of this feature is to make these services part of the service package framework, so that these can be controlled on a per domain/user basis.

100.3 Overview

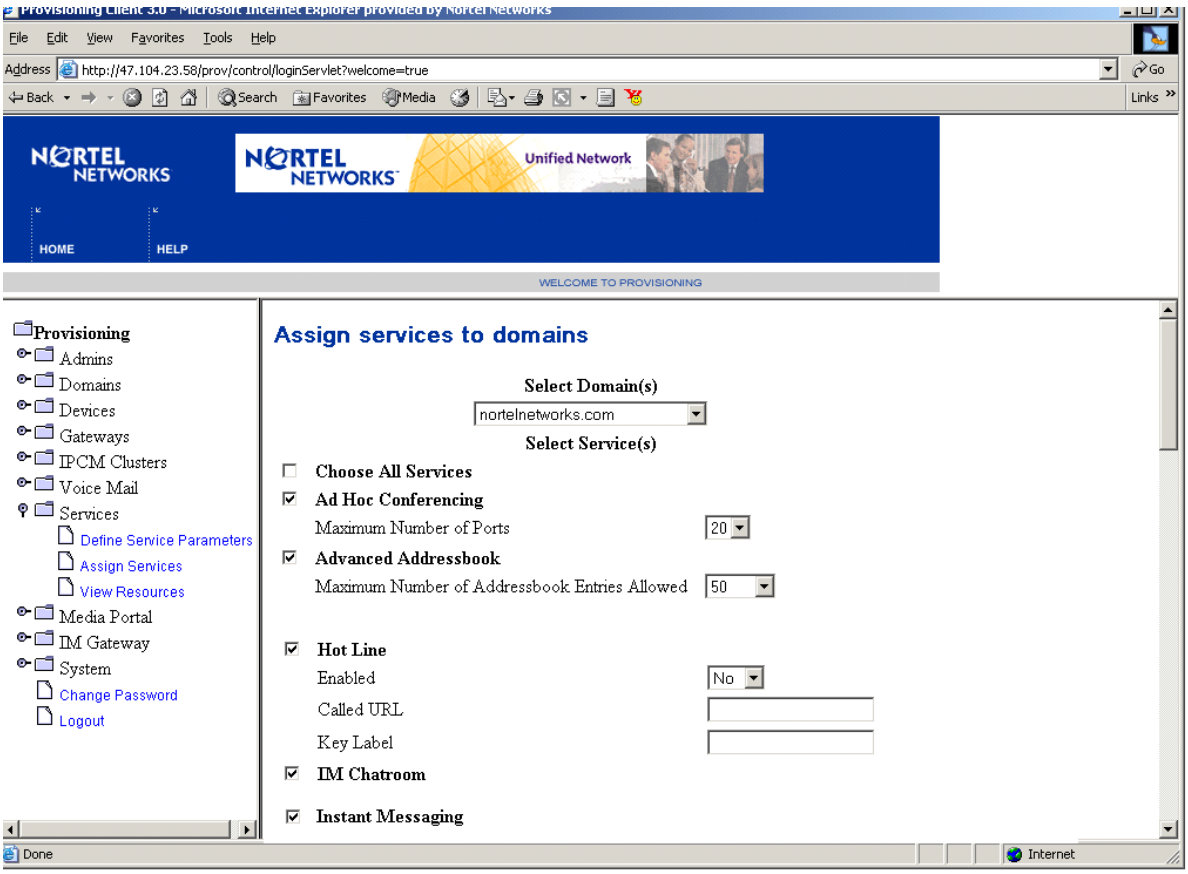
These new services enable an MCS customer to limit the availability of these services to the end users and will provide an option to create service packages at a more granular level.

100.4 Feature Description

100.4.1 Administrator Configuration and Provisioning

100.4.1.1 Instant Messaging Service

Figure 1 Assign Services to Domain(s)



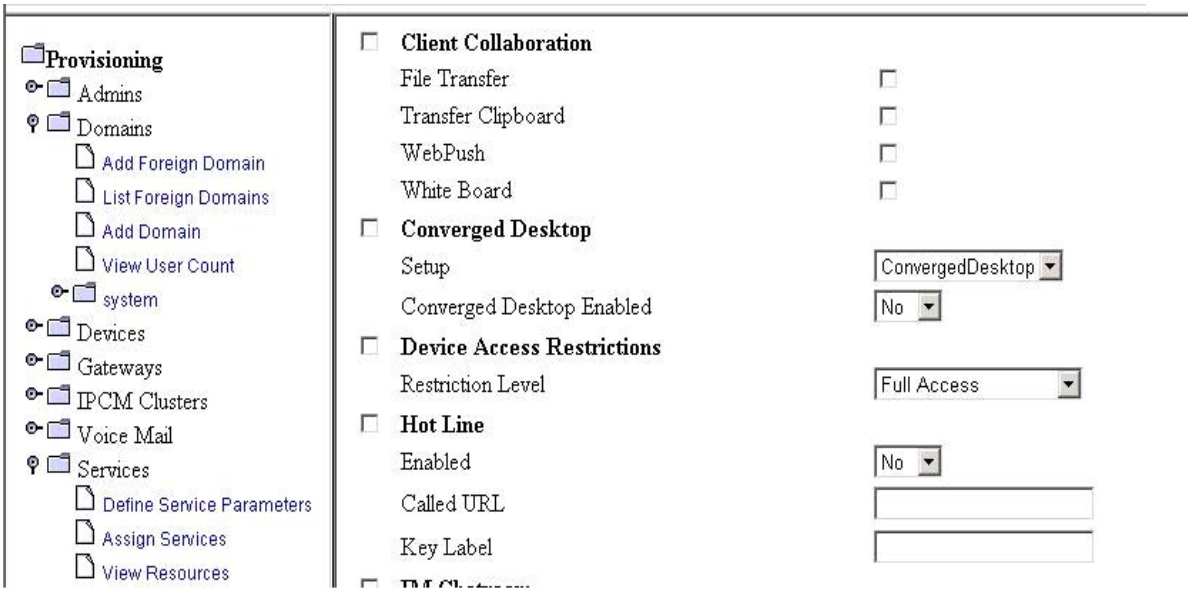
As part of this feature a new service called “Instant Messaging” is defined.

The above web page shows how this service can be assigned to domain(s) in order to include it in the service packages created within that domain.

The “IM Chatroom” service is dependent on the “Instant Message” service. Therefore, the “IM Chatroom” service cannot be assigned to a service package without the “Instant Messaging” service. This dependency is enforced by the Provisioning Client and the Provisioning Module’s service framework.

100.4.1.2 Client Collaboration Service

Figure 2 Assign Services to domain(s)

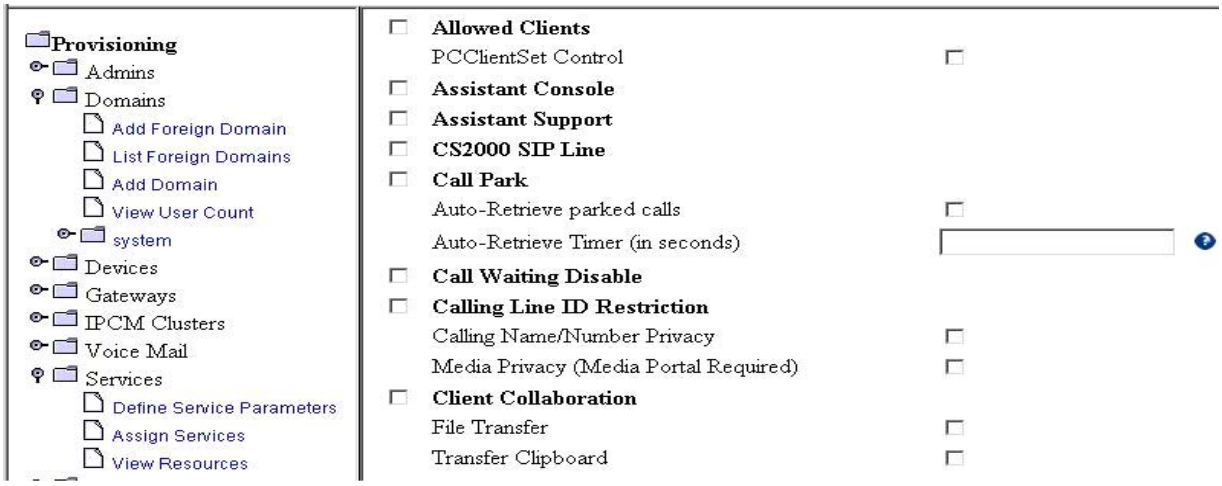


As part of this feature a new service called “Client Collaboration” is defined.

“File Transfer”, “Whiteboard”, “Transfer Clipboard” and “Web Push” are each considered a collaboration that is exposed for use by the subscriber using the Multimedia PC Client as provisioning parameters of the “Client Collaboration” Service.

100.4.1.3 Allowed Clients Service

Figure 3 Assign Services to domain(s)



As part of this feature a new service called “Allowed Clients” is defined. This service will have all the different clients as parms. A new parm called “PC ClientSet Control ” is defined under this service. Interaction of the PC Client with the Nortel i200x phone is controlled by this service parm.

100.4.2 Feature Provisioning

None.

100.4.3 Instant Messaging Service

A new service called “Instant Messaging (IM)” will be defined as part of this feature. A user who has this service in their service package will be able to send/ receive instant messages to/ from other users in the system via the PC Client, PC Client Set, or device as controlled by the IPCM.

Removing this service from the user’s service package will take away this ability from the user. In addition the PC Client will no longer display the icon for this service. Chat services will also be disabled since instant messaging service is necessary to participate in chat services. IM Broadcast service will also be disabled. The IM Routing option will not be available for the user if the IM service is not present in this service package.

The service package contains indication of whether to enable instant messaging for the user. When the “Instant Messaging” service is included in the service package, instant messaging will function on the PC Client, PC Client Set, and IPCM device as it did previous to this feature.

When the “Instant Message” service is absent from the user’s service package, the following changes in functionality will be observed as described in the following subsections.

100.4.3.1 Instant Messaging Service - Multimedia PC Client

This section describes Multimedia PC Client functionality that is removed when the “Instant Messaging” service is absent from the user’s service package.

100.4.3.1.1 Main GUI

The Instant Message and Chat icons will not be present on the icon panel of the main GUI.

Figure 4 Instant Message and Chat Icons on Main GUI

100.4.3.1.2 Quick Start Menu

The Instant Message and Chat icons will not be present on the the Quick Start panel.

Figure 5 Instant Message and Chat Icons on Quick Start Pane

100.4.3.1.3 Session Frame

The Session Frame no longer shows an icon for opening the Instant Message panel. The user will not be able to access the panel, nor will the panel be opened if the PC Client receives an instant message.

Figure 6 Session Frame without Instant Message Icon

100.4.3.1.4 In Session Frame

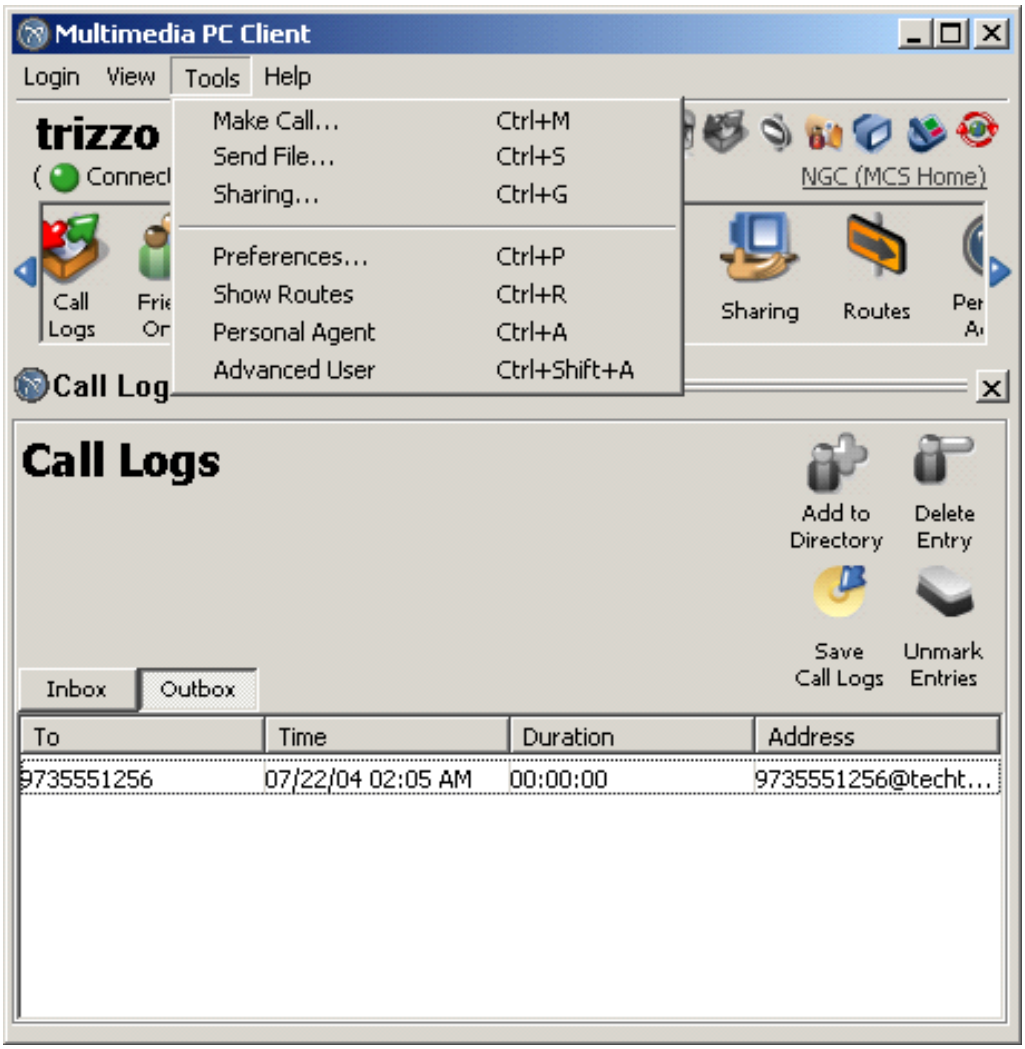
The In Session Frame will no longer show the “Reply with IM” option if the user does not have Instant Messaging Service.

Figure 7 Session Frame without Reply with IM option

100.4.3.1.5 Menus

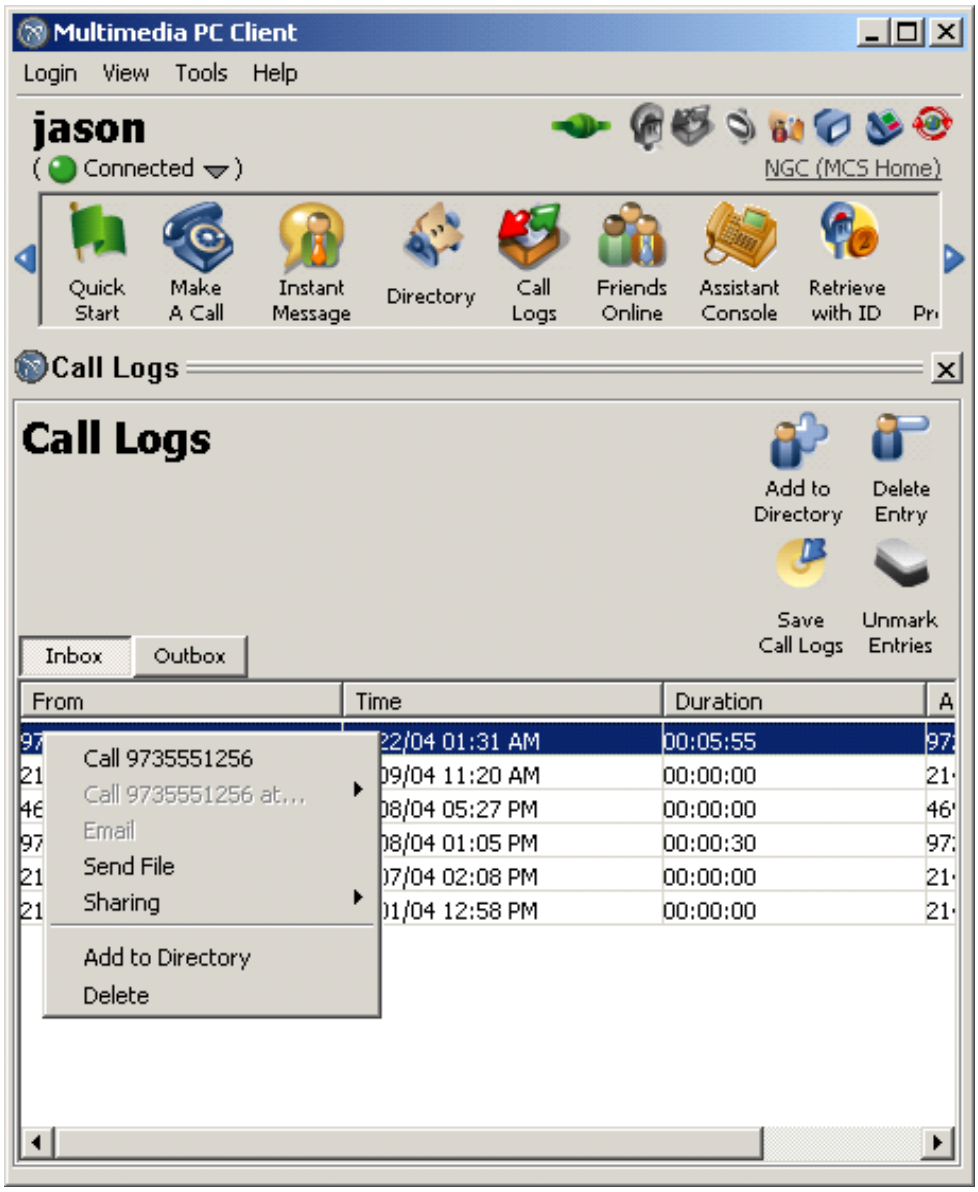
The “Instant Message” and “Start Chat” options will not be present on the Tools menu of the main GUI.

Figure 8 Tools Menu without Instant Message and Chat Items



The right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Send Instant Message” or “Start Broadcast” options.

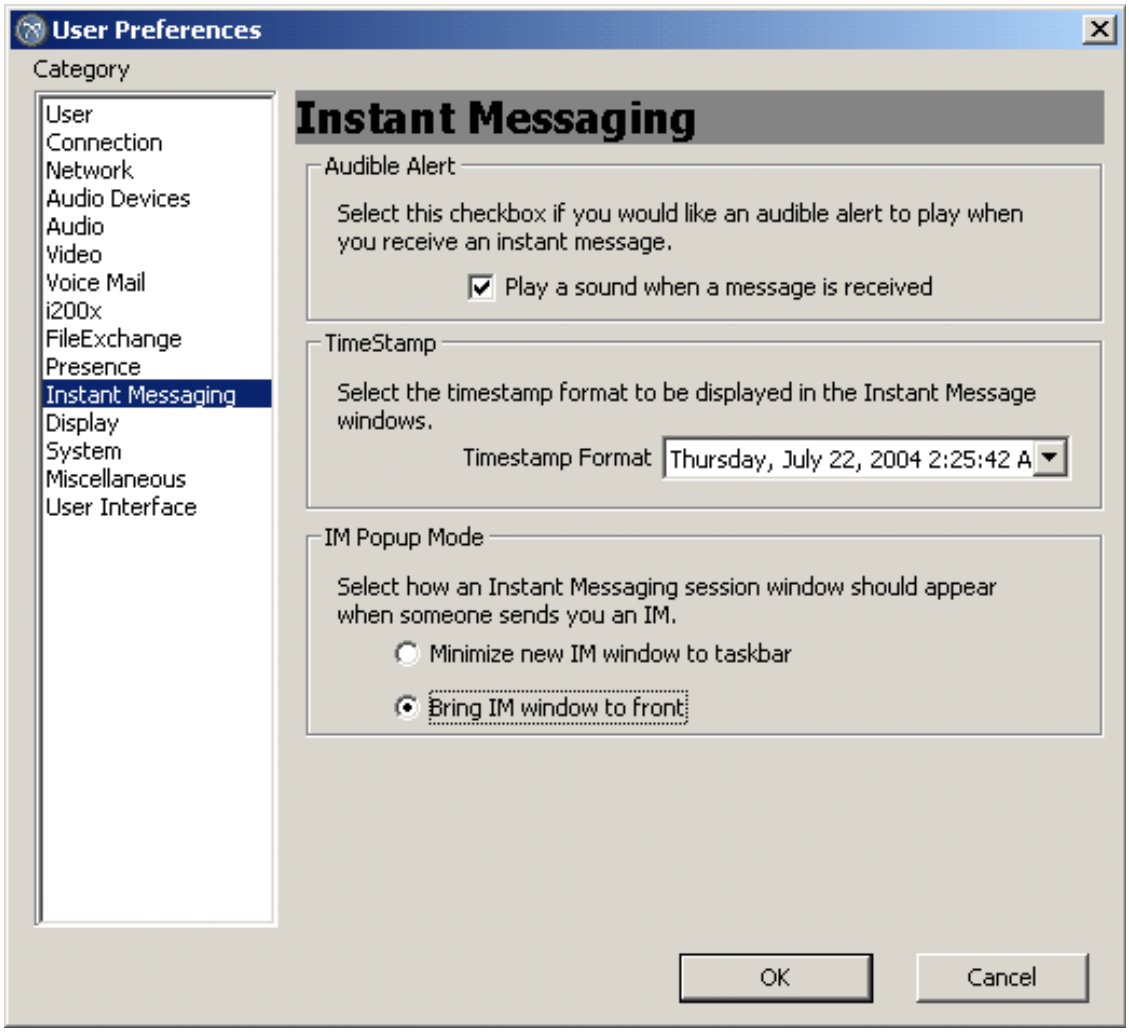
Figure 9 Call Logs Right-Click Menu without Instant Message and Broadcast Items



100.4.3.1.6 1.1.3.1.1.6Preferences

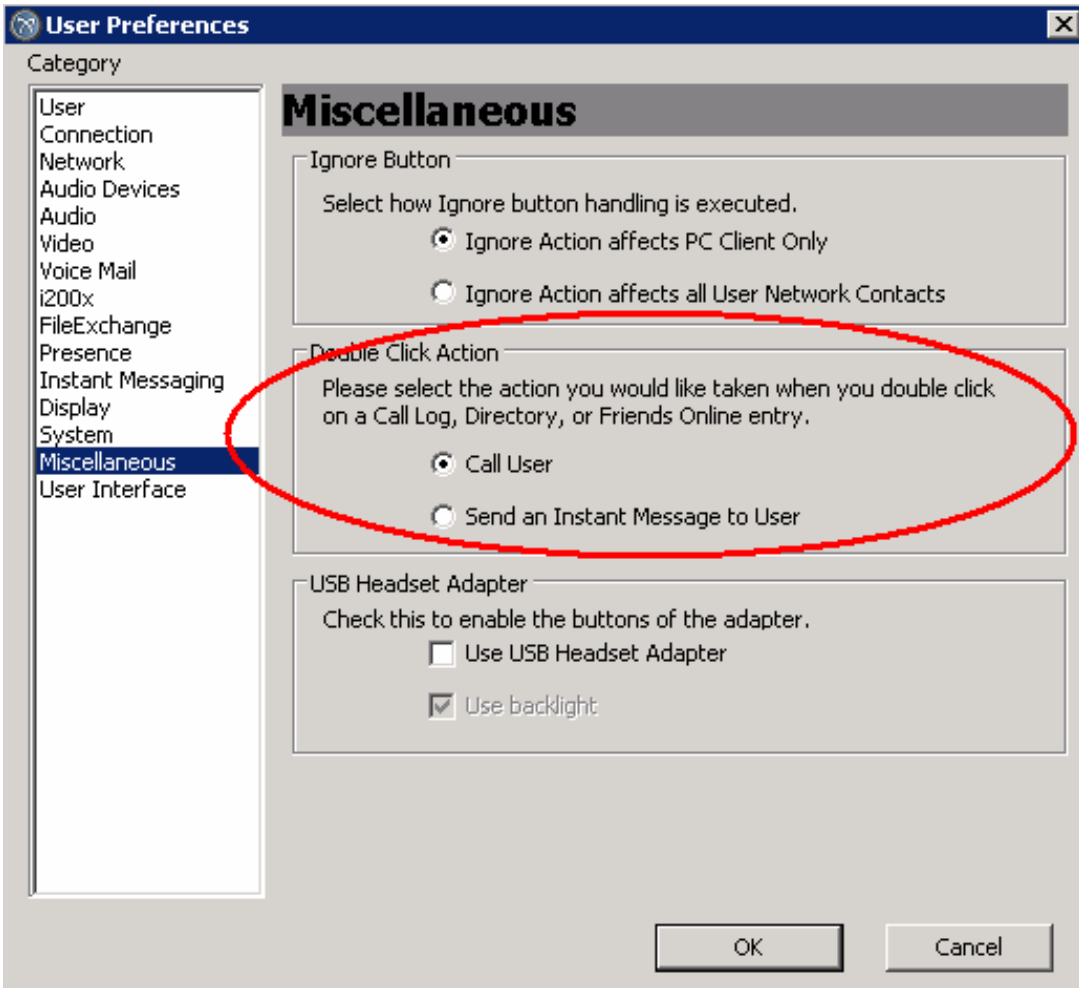
The “Instant Messaging” tab will not be included on the Preferences Panel.

Figure 10 IM tab will not be present when Instant Messaging is disabled



In addition to the Instant Messaging tab, there is a reference to Instant Messaging in the Miscellaneous tab – you can set whether a double-click in the Directory initiates a call or an IM. The entire “Double-Click Action” section of the Miscellaneous tab will not be included, and the double-click action will always be to initiate a call.

Figure 11 Double-click action will not be shown and will always initiate a call



100.4.3.1.7 Messaging

With Instant Messaging disabled, the PC Client will not be able to receive instant messages. If the client does receive an instant message, it will respond to the SIP MESSAGE message with a SIP 415: Unsupported Media Type response.

The same response will be sent if the user receives an invitation to a chat room. The message that is displayed to the user in the GUI will be

“Contact does not have support for instant messages.” for IMs and

“Contact does not have support for chat.” for chatroom invitations.

100.4.3.2 Instant Messaging Service - Multimedia PC Client Set

This section describes Multimedia PC Client Set (200x device that is controlled by the Multimedia PC Client) functionality that is removed when the “Instant Messaging” service is absent from the user’s service package.

100.4.3.2.1 Service Menu

When the “Instant Messaging” service is not included in the user’s service package, the PC Client restricts the device display of the Instant Messaging service menu option as depicted in the following figure.

Note: The option “Send IM” is removed from the Services menu.

Figure 12 Services Menu without “Instant Messaging” Service

100.4.3.2.2 Friends and Address Book

When the “Instant Messaging” service is not included in the user’s service package, the PC Client controlling the 200x device restricts the ability for the user to send an IM from the Friends and Address book as depicted in the two figures that follow.

Note: The option “Send IM” is removed as it was previously available via soft key 3.

Figure 13 Friends Menu without “Instant Messaging” Service

When a user has the “Instant Messaging” service, the Address Book allows the user the abilty to “Send IM (via soft key 2) when viewing the details for a given contact. When the user does not have the “Instant Messaging” service, “Send IM” functionality is removed from the Address Book.

Figure 14 Address Book without “Instant Messaging” Service

100.4.3.3 Instant Messaging Service – IPCM Device

This section describes device functionality that is removed from the user’s devices (200x devices controlled by the IPCM) when the “Instant Messaging” service is absent from the user’s service package.

100.4.3.3.1 Service Menu

When the “Instant Messaging” service is not included in the user’s service package, the IPCM restricts display of the Instant Messaging service menu option as depicted in the following figure: Services Menu without “Instant Messaging” Service.

Note: The option “Send IM” is removed from the Services menu.

Figure 15 Services Menu without “Instant Messaging” Service

100.4.3.3.2 Friends and Address Book

When the “Instant Messaging” service is not included in the user’s service package, the IPCM restricts the ability for the user to send an IM from the Friends and Address book as depicted in the following figure.

Note: The option “Send IM” is removed as it was previously available via soft key 3.

Figure 16 Friends Menu without “Instant Messaging” Service

When a user has the “Instant Messaging” service, the Address Book allows the user the abilty to “Send IM (via soft key 2) when viewing the details for a given contact. When the user does not have the “Instant Messaging” service, “Send IM” functionality is removed from the Address Book.

Figure 17 Address Book without “Instant Messaging” Service

100.4.3.3.3 Assistant Console

When the “Instant Messaging” service is not included in the user’s service package, the IPCM restricts the ability for the user to send an IM from an Assistant Console Quick Actions menu for an “Assistant Console” service subscriber. For more information on the “Assistant Console” service, please see “FTR308 Boss-Secretarial Services” Fuctional Description.

Note: Note: The option “IM” is removed as it was previously available via soft key 3.

Figure 18 Assistant Console Quick Actions without “Instant Messaging” Service

100.4.3.3.4 Messaging

With Instant Messaging disabled, the IPCM device will not be able to receive instant messages. If the IPCM receives an instant message for a user that does not have the “Instant Messaging” service, it will respond to the SIP MESSAGE message with a SIP 415: Unsupported Media Type response.

The message that is displayed to the user in the GUI will be

“Contact does not have support for instant messages.”

100.4.3.4 Client Collaboration Service

A new service called “Client Collaboration” is defined as part of this feature. “File Transfer”, “Whiteboard”, “Transfer Clipboard” and “Web Push” are each considered a collaboration that is exposed for use by the subscriber using the Multimedia PC Client as provisioned parameters of the “Client Collaboration” Service.

If the user’s service package does not contain the “Client Collaboration” service or the respective collaboration parameters are not enabled, then the respective collaboration functionality on the Multimedia PC Client is disabled

as described in the following subsections. The service “Client Collaboration” is used to define if the user can receive any collaboration form other users. If the service is present, then the user will be able to receive all kinds of collaboration requests from other users. The individual service parms are used to define if the user can initiate any collaboration requests. If the parms are not present then the user will not be able to initiate any collaboration request.

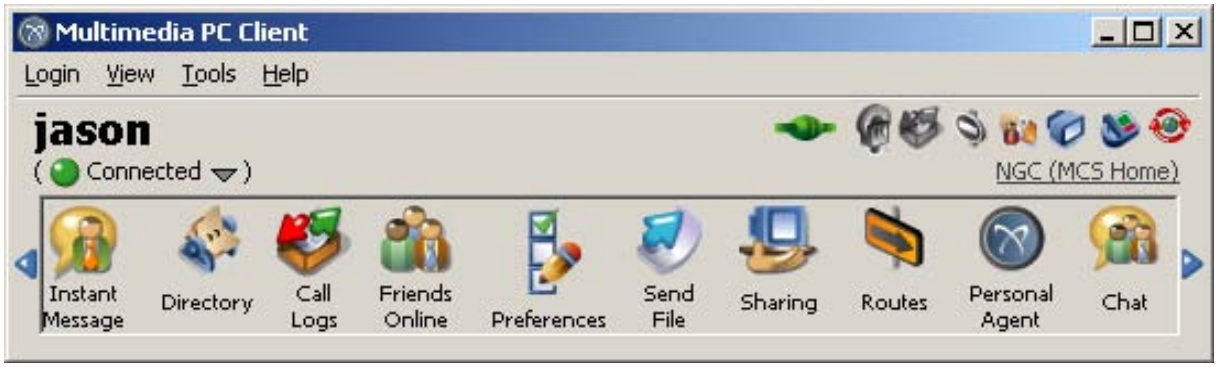
100.4.3.4.1 File Transfer

This section describes how the File Transfer functionality is restricted on the PC Client when the “File Transfer” collaboration is disabled in the service package.

100.4.3.4.2 Main GUI

The *Send File* icon will not be present on the icon panel of the main GUI.

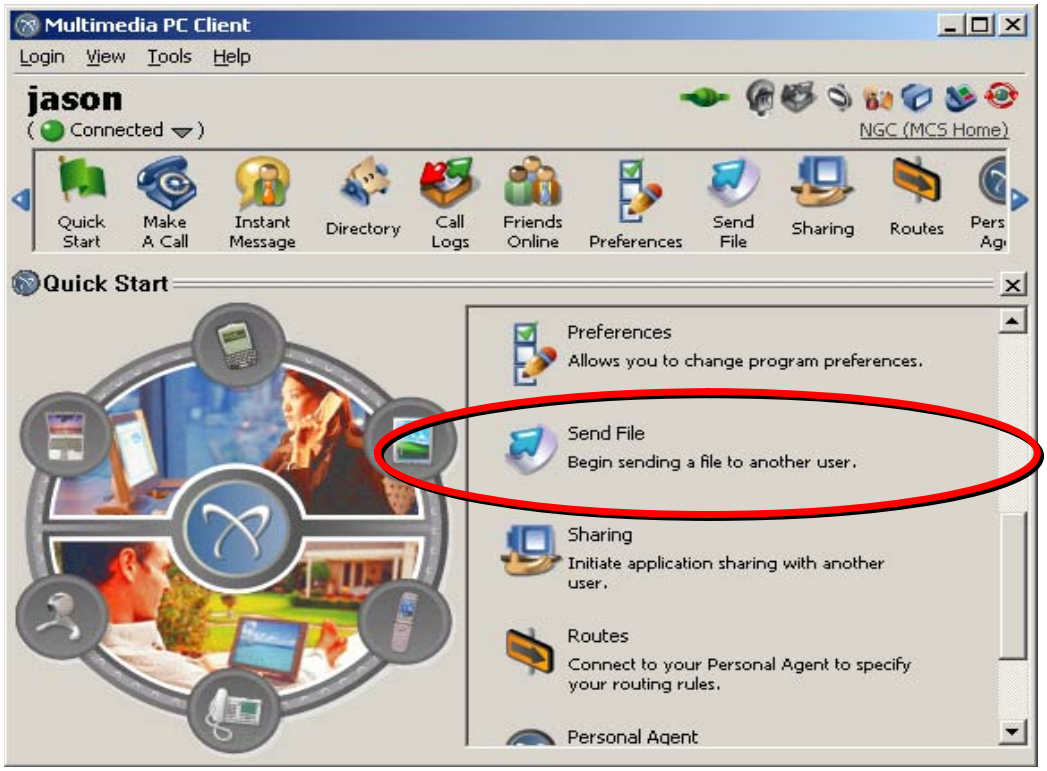
Figure 19 Send File Icon on the main GUI Icon Panel



100.4.3.4.3 Quick Start Menu

The Send File icon will not be present on the the Quick Start panel.

Figure 20 Send File Icon on Quick Start Panel



100.4.3.4.4 Session Frame

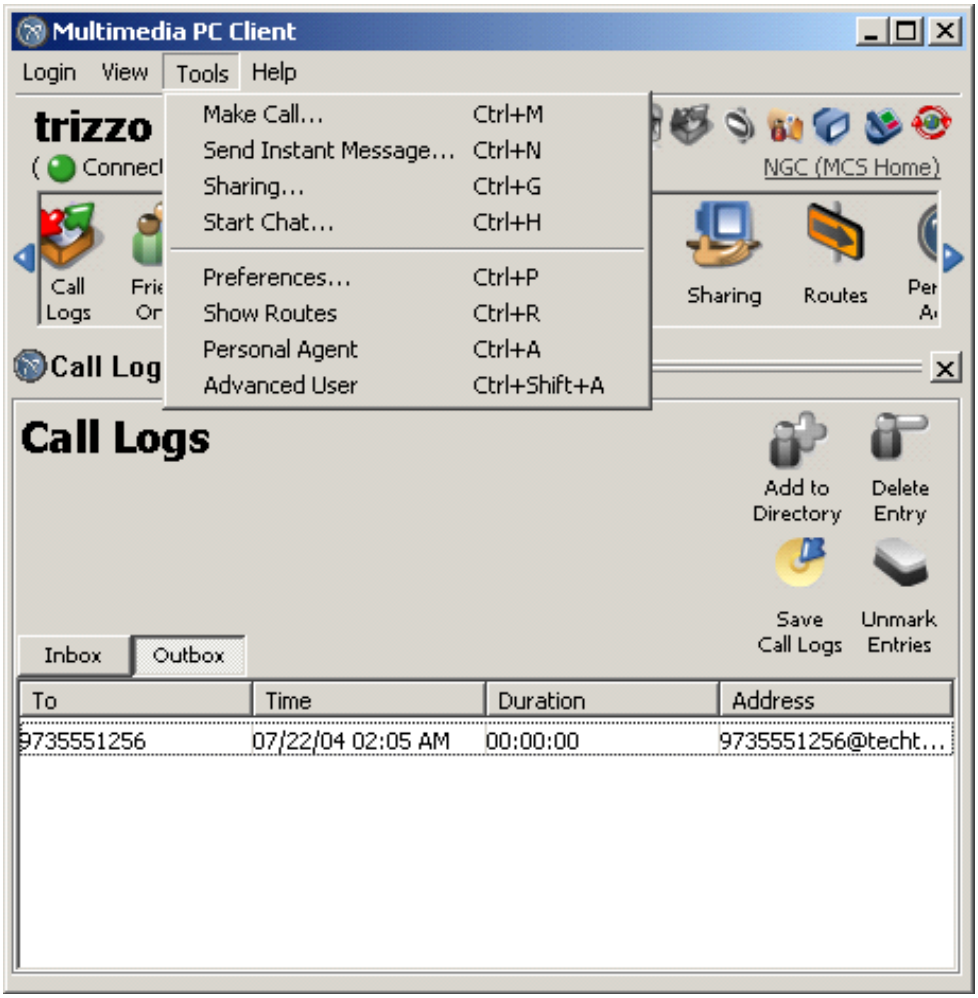
The Session Frame no longer shows the Send File icon. Additionally, the Share panel will not show its Send File icon either.

Figure 21 Collab Panel of the Session frame without the Send File Icon

100.4.3.4.5 Menus

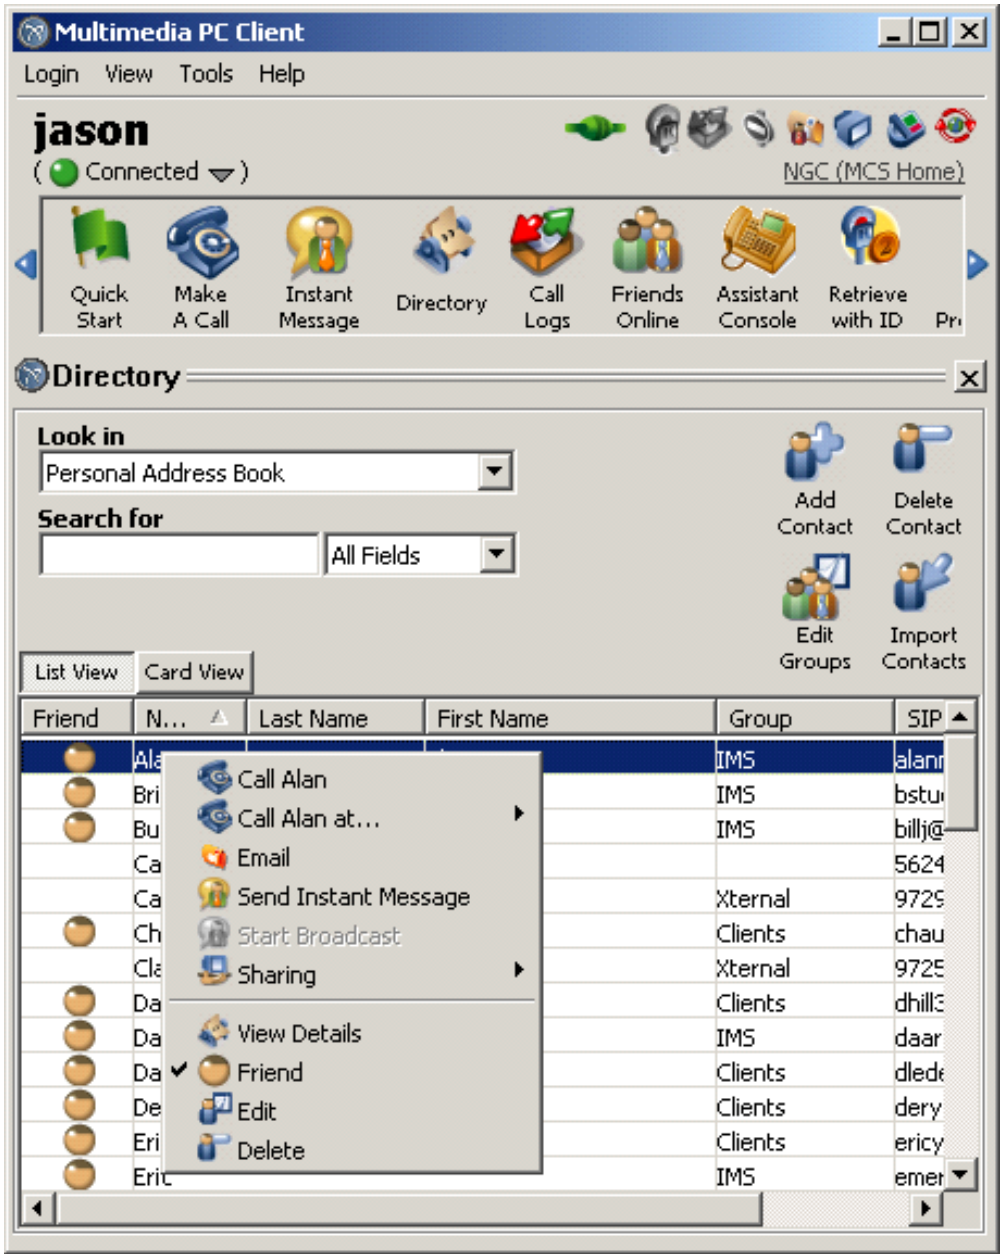
The “Send File” option will not be present on the Tools menu of the main GUI.

Figure 22 Tools Menu without the Send File Item



The right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Send File” option.

Figure 23 Right-Click Menu of the Directory Panel without the Send File Item



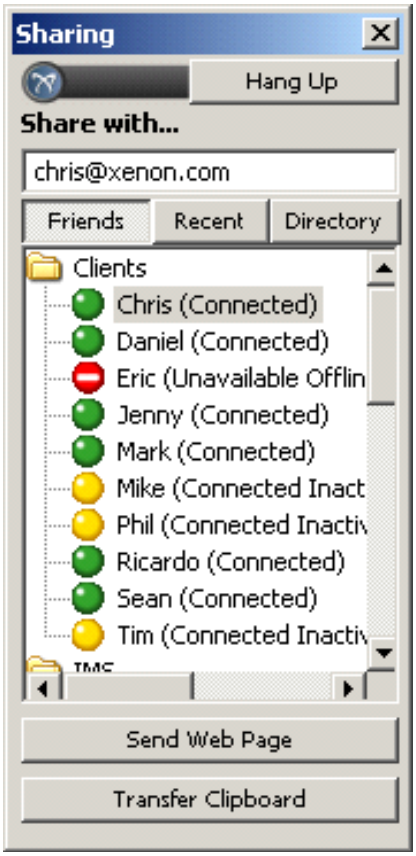
100.4.3.4.6 Whiteboard

This section describes how the Whiteboard functionality is restricted on the PC Client when the “Whiteboard” collaboration is disabled in the service package.

100.4.3.4.7 Share Dialog

The Share Whiteboard button will not be present on this dialog panel.

Figure 24 Share Dialog without the Share Whiteboard Button



100.4.3.4.8 Session Frame

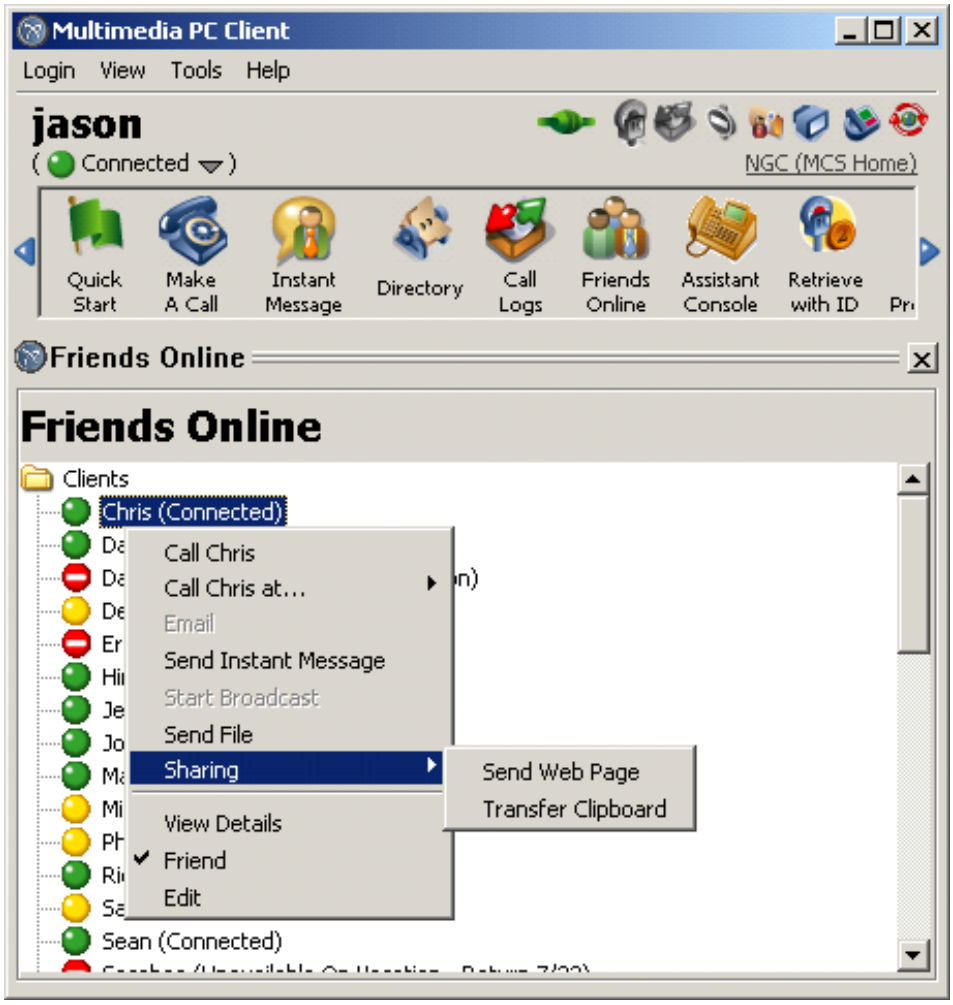
The Share panel on the Session Frame no longer shows the Share Whiteboard icon.

Figure 25 Collab Panel of the Session Frame without the Share Whiteboard Icon

100.4.3.4.9 Menus

The “Sharing” sub-menu of the right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Share Whiteboard”option.

Figure 26 Right-Click Menu of the Friends Panel without the Share Whiteboard Item



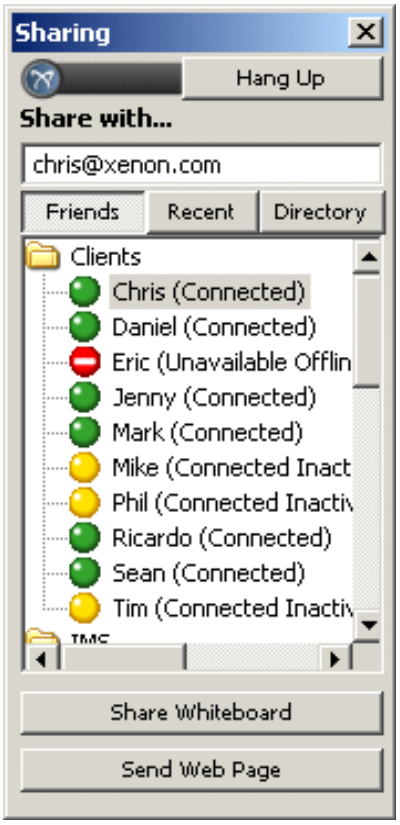
100.4.3.4.10 Transfer Clipboard

This section describes how the Transfer Clipboard functionality is restricted on the PC Client when the “Transfer Clipboard” collaboration is disabled in the service package.

100.4.3.4.11 Share Dialog

The Transfer Clipboard button will not be present on this dialog panel.

Figure 27 Share Dialog without the Share Whiteboard Button



100.4.3.4.12 Session Frame

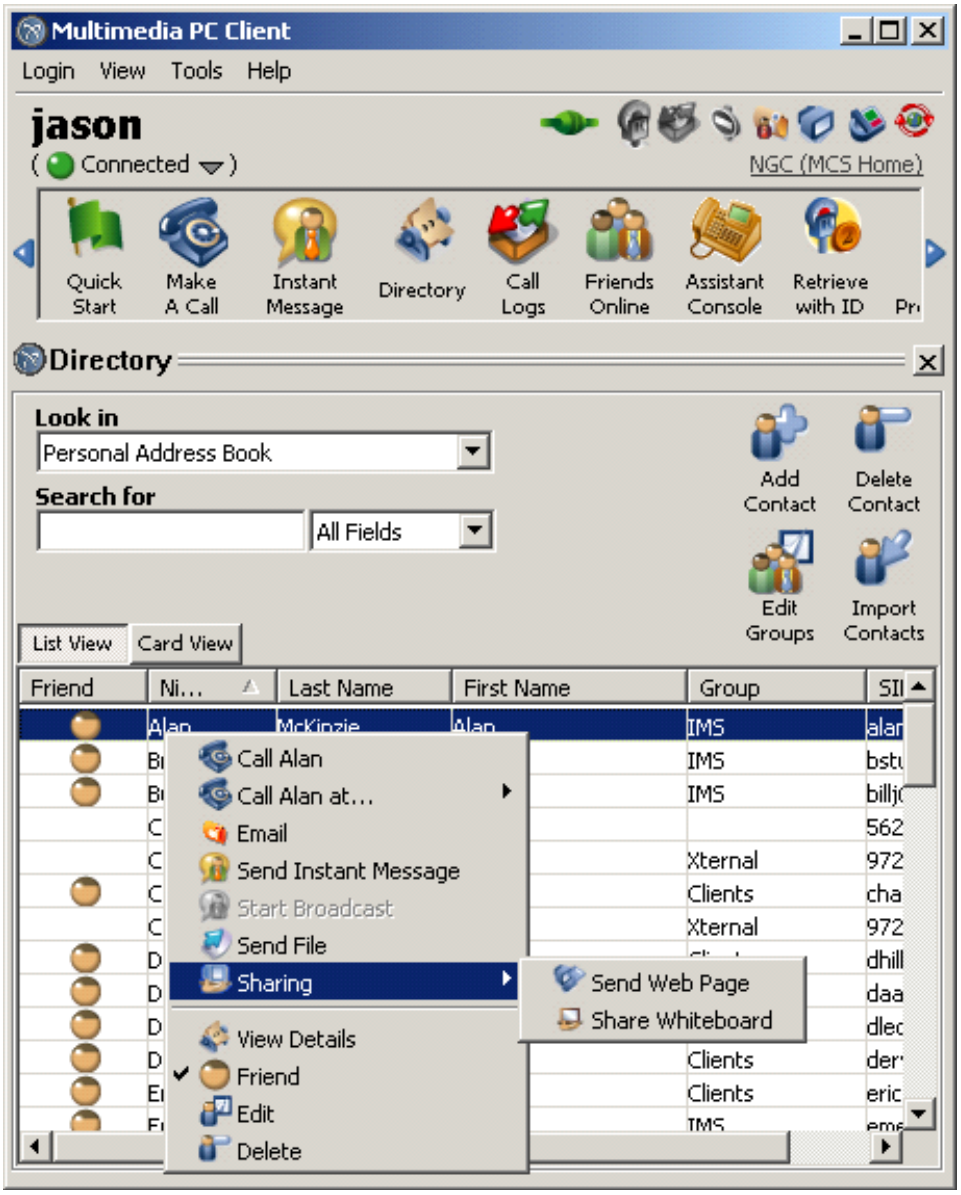
The Share panel on the Session Frame no longer shows the Transfer Clipboard icon.

Figure 28 Collab Panel of the Session Frame without the Transfer Clipboard Icon

100.4.3.4.13 Menus

The “Sharing” sub-menu of the right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Transfer Clipboard” option.

Figure 29 Right-Click Menu of the Directory Panel without the Share Whiteboard Item



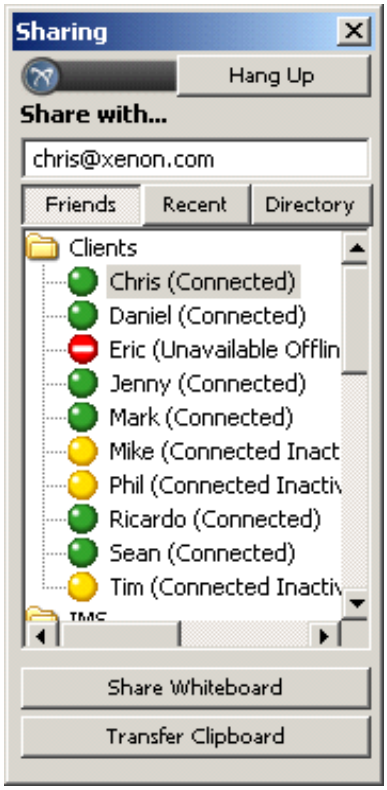
100.4.3.5 Web Push

This section describes how the Web Push functionality is restricted on the PC Client when the “Web Push” collaboration is disabled in the service package.

100.4.3.5.1 Share Dialog

The Send Web Page button will not be present on this dialog panel.

Figure 30 Share Dialog without the Send Web Page Button



100.4.3.5.2 Session Frame

The Share panel on the Session Frame no longer shows the Send Web Page icon.

Figure 31 Collab Panel of the Session Frame without the Send Web Page Icon

100.4.3.5.3 Menus

The “Sharing” sub-menu of the right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Send Web Page” option.

Figure 32 Right-Click Menu of the Friends Panel without the Send Web Page Item

100.4.3.6 Additional Behavior

In addition to the functionality described in the previous sections for the individual collaboration, the following behaviors are also present when disabling collaboration functionality.

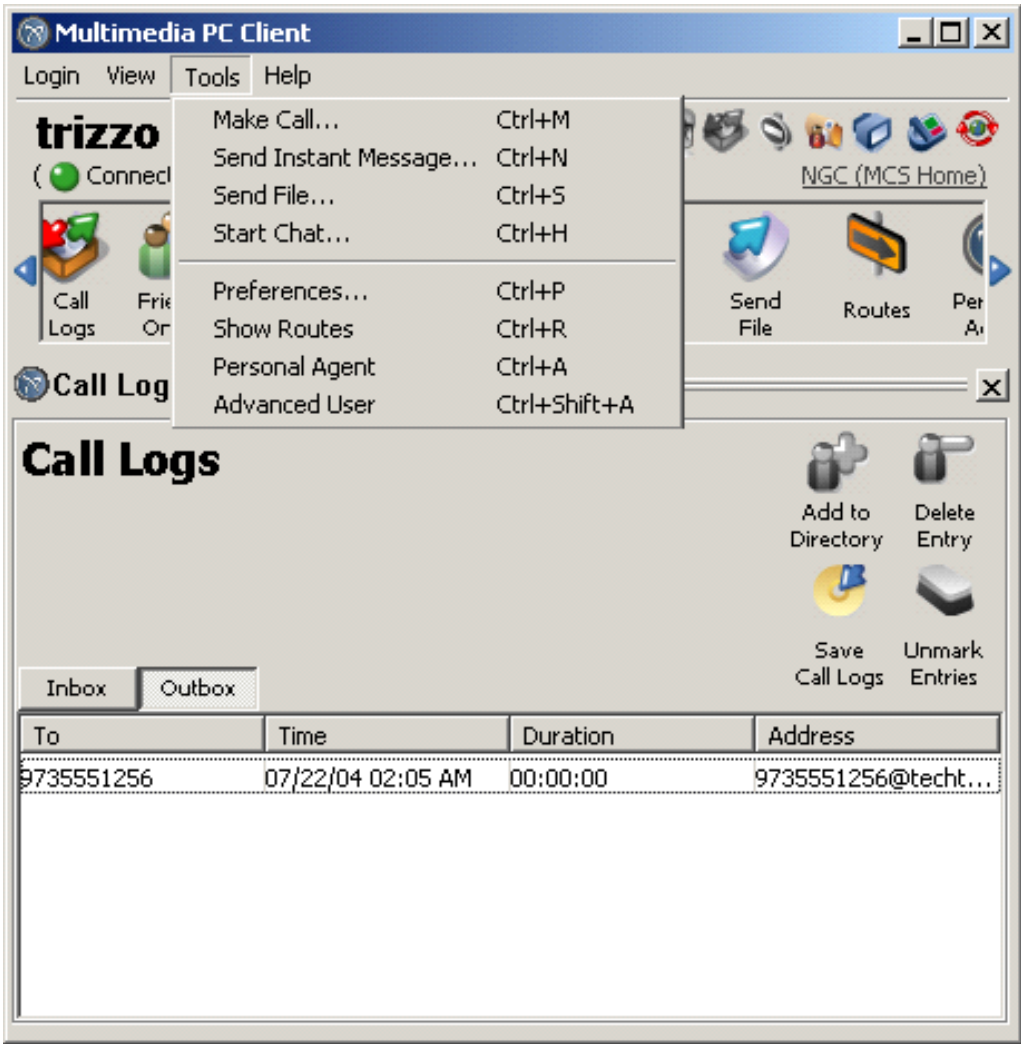
100.4.3.6.1 Collective Sharing Service

Since the Whiteboard, Transfer Clipboard, and Web Push collaboration functionality is grouped for the user on the PC Client as “Sharing” functions, when all three of these collaborations are disabled through the service framework, the “Sharing” functionality will also be disabled as identified in the following subsections.

100.4.3.6.2 Main GUI

The Share icon will not be present on the icon panel of the main GUI.

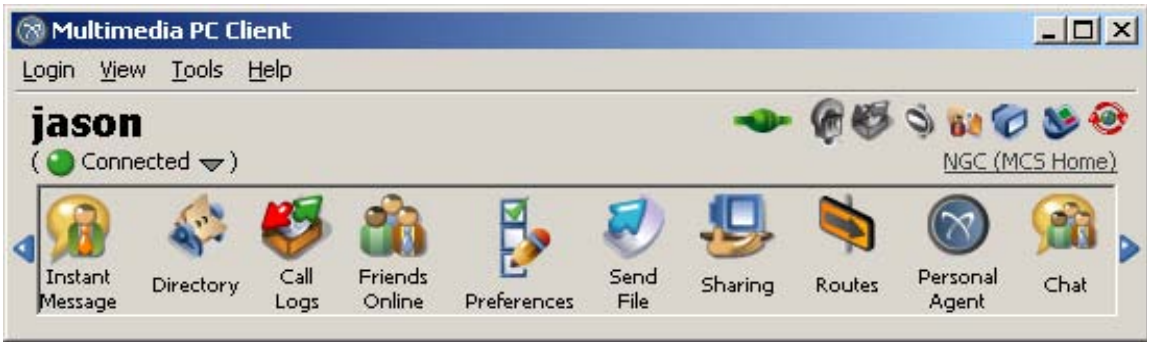
Figure 33 Tools Menu without the Sharing Item



100.4.3.6.3 Quick Start Menu

The Share icon will not be present on the the Quick Start panel.

Figure 34 Sharing Icon on the Main GUI Icon Panel



100.4.3.6.4 Session Frame

The Session Frame will continue to show the Share icon if the File Transfer collaboration is enabled. This icon serves to open and close the collaboration panel on the Session Frame, which is also used for File Transfer. If File Transfer is also disabled, the Share icon will not be present on the Session Frame.

Figure 35 Collab Panel of the Session Frame with only the Send File Icon

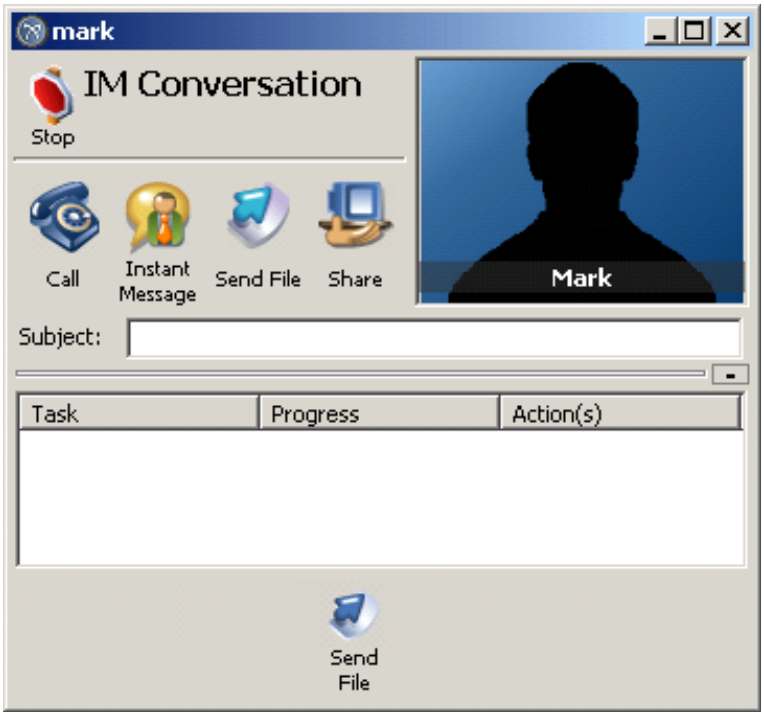


Figure 36 Session Frame without the Sharing and Send File Icons

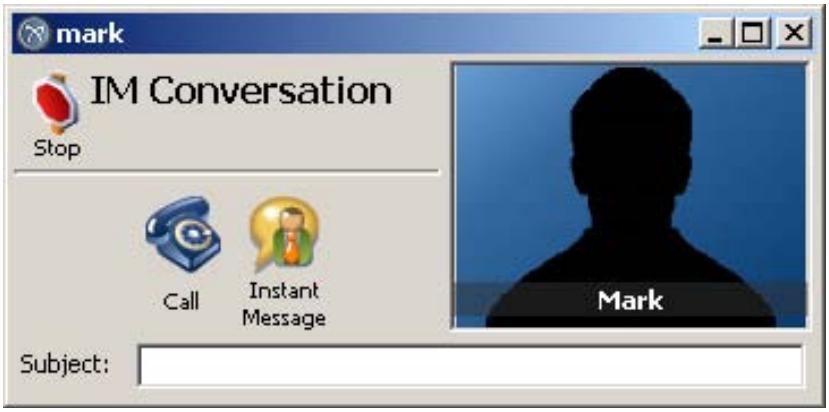
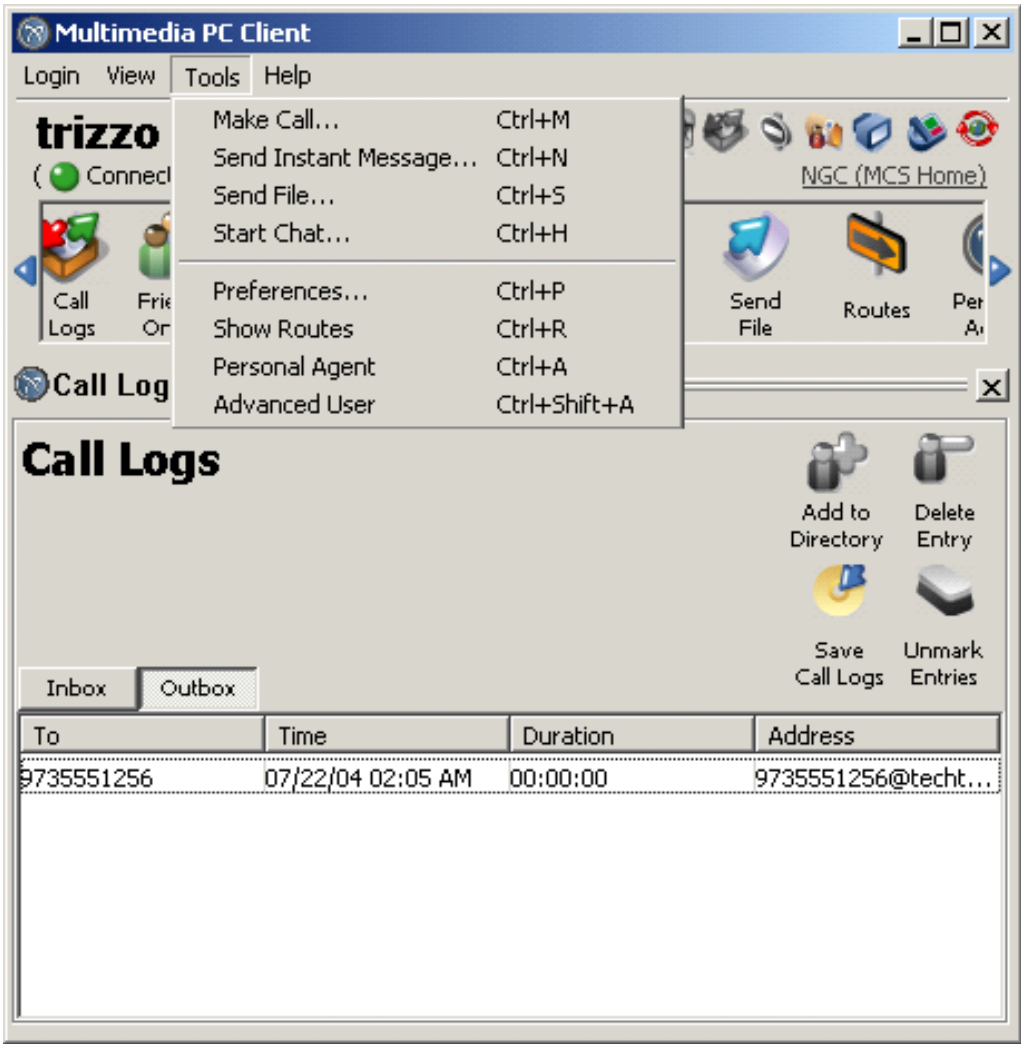


100.4.3.6.5 Menus

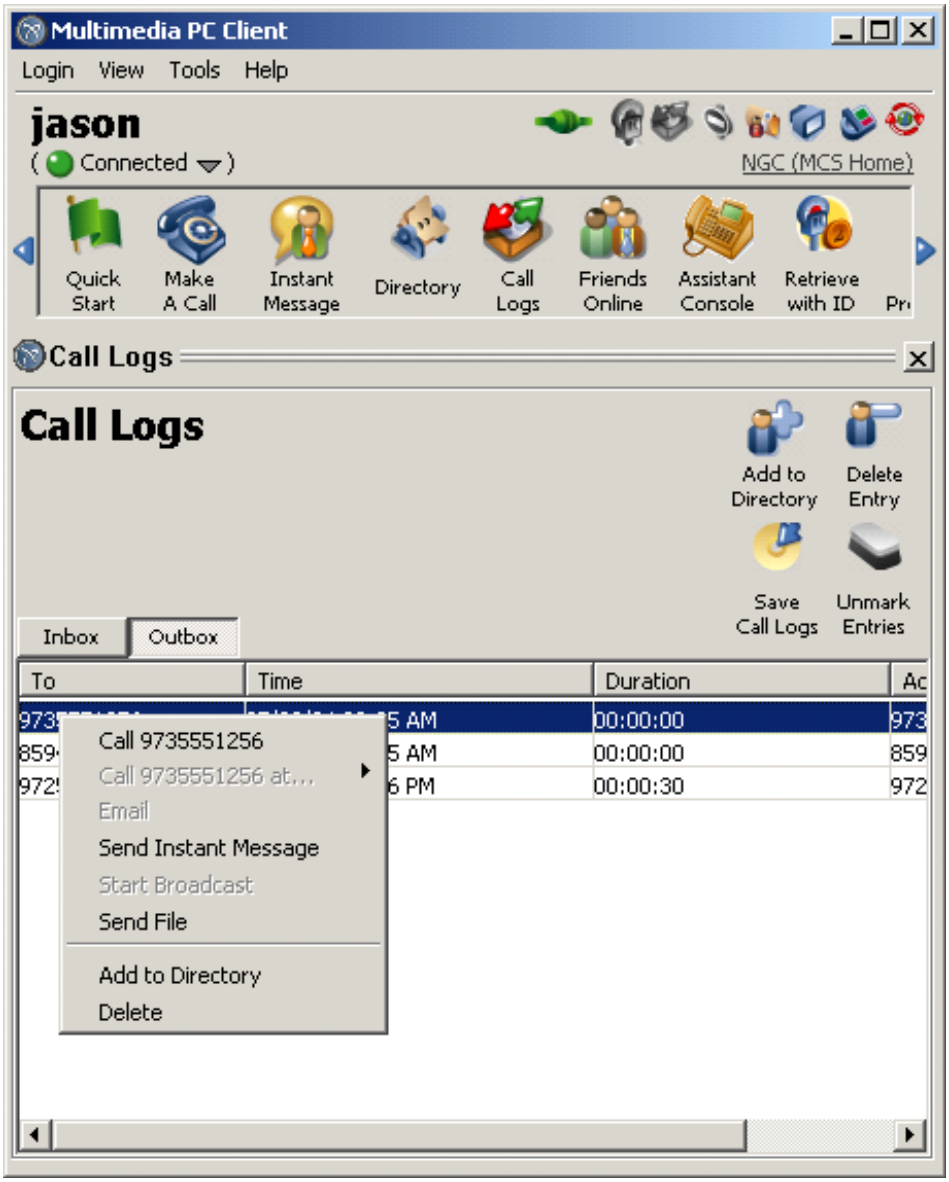
The “Share” option will not be present on the Tools menu of the main GUI.

Figure 37 Tools Menu without the Sharing Item



The right-click popup menus on the Call Logs, Address Book, and Friends panels will not contain the “Sharing” sub-menu.

Figure 38 Right-Click Menu of the Call Logs without the Sharing Sub-Menu



100.4.3.6.6 Messaging

When any collaboration is disabled, the PC Client will respond with a SIP 415: Unsupported Media Type response to any SIP MESSAGE message which invokes a disabled collaboration. MESSAGE messages invoking enabled services will receive SIP 200 OK responses as before.

> ***Note:*** The SIP message that is returned may vary depending on the type of collaboration INVITE that is received.

The message that is displayed to the user in the GUI will be

"Contact does not have support for [collab service]." where [collab service] may be file exchange, whiteboard, application sharing, etc.

100.4.3.7 PC Client Control of Etherset Service

A new service parm called "PC ClientSet Control " is defined as part of the new service "Allowed Clients" . Interaction with the Nortel i200x phone is exposed for use by the subscriber using the Multimedia PC Client as provisioned parameters of the "Allowed Clients" Service.

If the user's service package does not contain the "PC ClientSet Control " parm then the i200x interaction functionality on the Multimedia PC Client is disabled as described in the following subsections.

100.4.3.7.1 Main UI

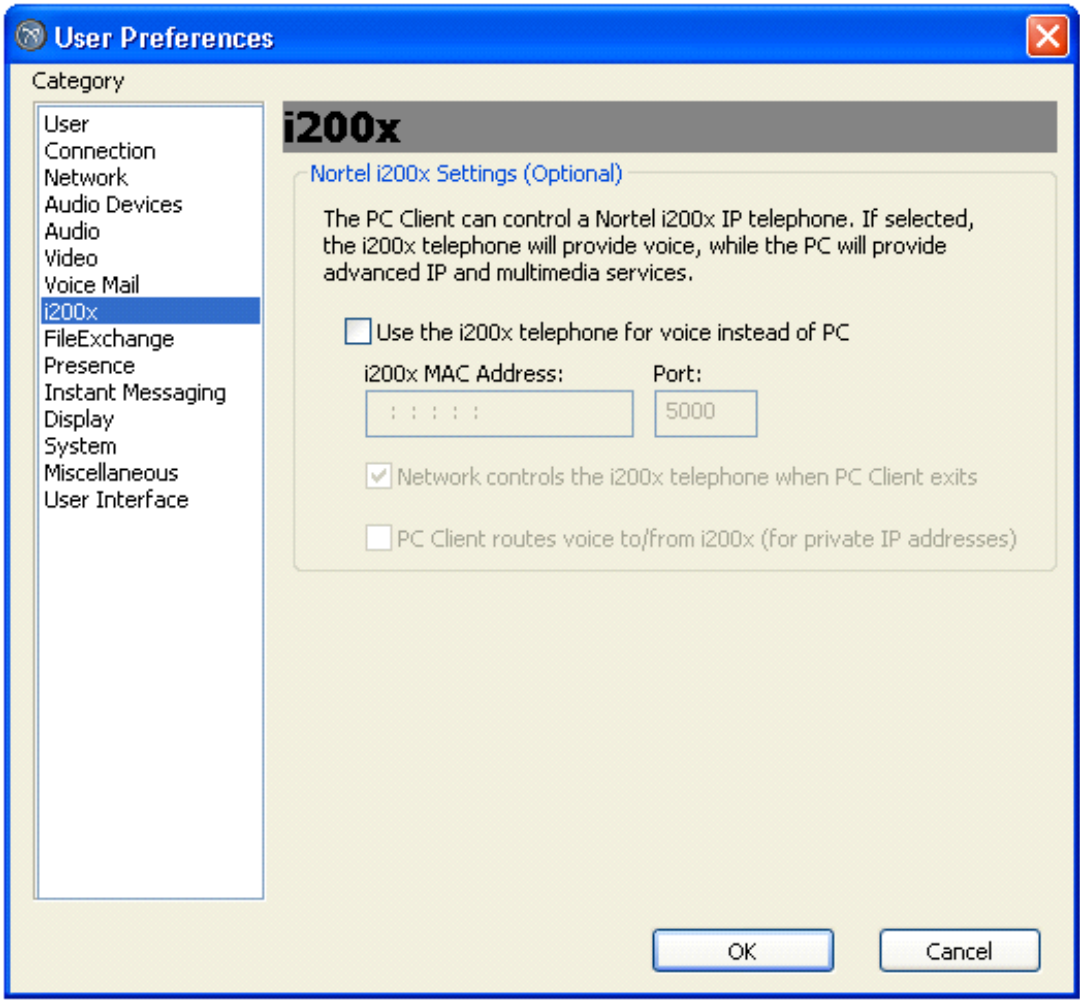
The changes on the main UI will consist in the removal of the i200x button.

Figure 39 i200x button is removed from main window

100.4.3.7.2 Preferences

The "i200x" tab will not be included on the Preferences Panel.

Figure 40 i200x page is removed



100.4.3.8 Special Cases

100.4.3.8.1 Services Disabled by Default

When the user is not logged in, any service whose availability depends on the service is assumed to be unavailable and therefore hidden in the UI and disabled at the network level. Therefore, when the user is logged out of the PC Client, the IM and Sharing services will not be visible or functional. Only when the user has logged in and retrieved the service package will the enabled services activate.

Note: Default behavior will be just like Assistant Console feature, which does not appear by default but pops up when the service package is downloaded with the Boss/Secretary service enabled.

100.4.3.8.2 Dynamic Change of Service Package

If a user is logged in and suddenly receives a new service package which disables one of the granular services, all activity related to the service will be stopped and all UI disabled and hidden except for the following:

- In the case of an IM session in progress, the send button will be disabled and no further IMs can be sent or received. The IM panel remains open until the user closes it, allowing the user to save the IM conservation. No new IM panels can be opened.

Figure 41 IM Send Button Disabled

- Any collaborations in progress (file transfers, whiteboard session, etc.) will be allowed to finish, but no new collaborations can begin.

Figure 42 Collaborations in Progress

If PCClientSet Control service parm is lost, the i200x phone will continue to be controlled by the soft client until the connection is lost or the client is restarted.

100.4.3.8.3 Additional Client Behavior

- It is possible to still display a disabled UI control that would normally be hidden when a service is not available. This is done by setting the control's "collapsetype" property in the XML skin to "none". For example, in the main window's main.xml skin, set the IM button (mainWindowInstantMessaging component) property collapsetype=none. When the main window is loaded and IM is not an available service, the IM button will be visible but disabled.
- Systray menu options "Start Sharing...", "Start Send File..." and "Send Instant Message..." will be disabled and hidden if corresponding services are not available in the service package.
- IM and Collab buttons must collapse not only in the regular In Session window but also the Converged Desktop In Session window.

100.4.3.9 Personal Agent Enhancements

100.4.3.9.1 Instant Messaging Service

This service affects the Routes functionality of the Advanced Screening service in the following way:

- If a user does have the Instant Messaging service then the user will be able to send/receive any instant messages. Therefore the routes wizard will display the option for handling instant messages in the ‘Step 1. Initiate action’ screen.

As part of this feature, the routes wizard will be modified to display the Instant Messaging option only when the user’s service package contains the ‘Instant Messaging’ service.

The two variations of the screens are displayed as below.

Figure 43 Instant Messaging Present

100.7.3 Logs and Alarms

100.7.3.1 Change Log for User Service Package changes
Provisioning audit logs will be generated for user service package changes by the provisioning administrator's. The logs will have the following information.

a. The IP Address of the machine from which the operation was performed:

b. The admin name who is performing the operation

c. The command performed

d. Description

Here is the sample log for a user's service package change from package "silver" to "gold". In addition to the above information, the log will have the new service package name. The method name present in the log is "modifyExtendedUser", since that is the method used to perform the service package change.

PROV1_0 PROVC 606 INFO JAN05 12:17:06:207 MCP_4.0.0

RequestType:ProvClient, Username:admin, Command:Modify a single extended user (modifyExtendedUser) , IP Address:47.102.112.151, Comments: User name=[n1@nortel.com], User=[username:n1@nortel.com&firstname:n1&lastname:n1&servicepackage:gold]

Here is the sample log for the customization of a user's service package.In this case, the user's Presence and Unified Communications service preferences are being modified by the admin.

PROV1_0 PROVC 606 INFO JAN05 12:17:06:207 MCP_4.0.0

RequestType:ProvClient, Username:admin Command:Modify all preferences for a user (modifyAllUserPreferences), IP Address:47.102.112.151, Comments: User name=[n1@nortel.com], Service List=ListSize:2,ListContents[name:Presence,parms:(name:Report when inactive,value:N),(name:Report when on the phone,value:Y)&name:Unified Communications,parms:(name:Maximum Storage (in minutes),value:20),(name:Maximum Message Length (in seconds),value:180),(name:Maximum Number of Messages,value:50)]

100.8 Performance Management

Not Applicable.

100.8.1 Performance Management Strategy

Not Applicable.

100.8.2 Performance Management Tools and Utilities

Not Applicable.

100.8.3 Performance Measurements (PM), Operational Measurements (OM), and Stats

Not Applicable.

100.9 Upgrade

Since these services were part of the basic services that were supported by the clients in the previous releases (i.e. 3.0 ,2.0 ,1.1 etc), when the system is upgraded to 4.1/9.0, all the existing servicepackage's will be given the above set of services. This will enable the users to use these services when the system is upgraded to 9.0.

Also, since this functionality is implemented only on the clients, the customer has to update the clients used by the end-users to limit the availability of these new services to the end- users.

100.10 Restrictions and Limitations

- If a user's service package changes dynamically and a service that was enabled is suddenly disabled (such as IM), that service will be immediately disabled in the PCClient and will not be available for the user to use.
- The service Client Collaboration is used to define if the user can receive any collaboration requests. The individual service parms will define if the user can initiate any collab requests.
- PA behavior on Service Package changes. If a user who has the IM service is logged into the PA session and is creating routes and at the same time if his service package has been changed to remove the IM service, then the user will still be able to see the IM routing options but will not be able to save any routes or make any routes active which have the IM routing options in them. The user will not be able to see the IM options the next time he logs into the PA session. Same with the Send WebPage options. This is consistent with the current behavior in PA for other services.
- If a user has MeetMe service and no IM service, then he will not be getting MeetMe chair IM notifications.
- If a user has WebCollab and does not have the Client Collaboration service webpush parm, then web collaboration will not work.
- The enforcement for the availability of these services is done only at the client level
- UI components related to services which are not available will be hidden. Other visible UI components on the same dialog will not necessarily be re-centered to make up for excess space left by the hidden components.
- This feature does not have any impact or relation to the wireless communicator project.
- The wireless client will not be modified to enforce these new service restrictions.

101: Functional Description (FN): A00009829

101.1 Feature name and Feature ID

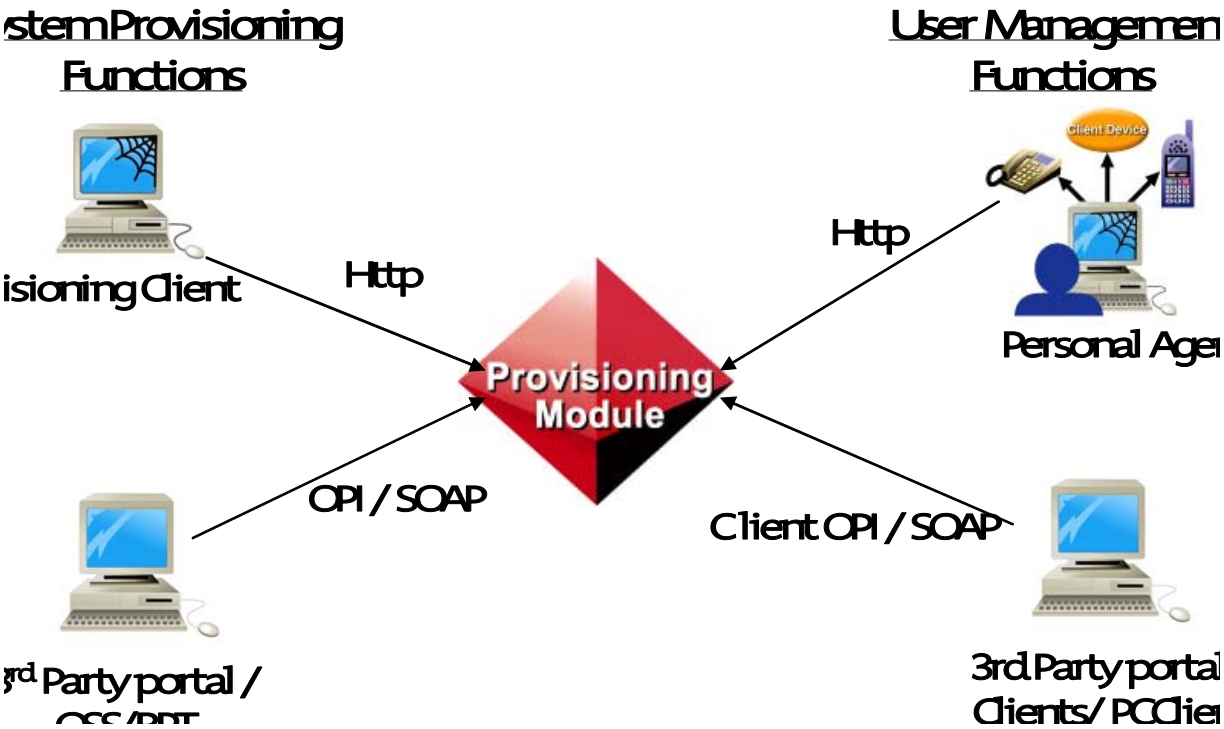
A00009829 - Subscriber Open Provisioning Interface Productization

101.2 Description

As of release MCS4.0, all the user management functions were performed via the provisioning interfaces like the Provisioning Client, Bulk Provisioning Tool(BPT) and/or the Open Provisioning Interface (OPI) and was limited to the provisioning administrators. The only interface available for the end users to manage their account was the Personal Agent (PA). Although, a small set of user related operations are available in the existing Client OPI interface, this is used only by the PCClient. However, this interface was never published for third party use like the provisioning OPI. This has given way to the Subscriber OPI (SOPI). The new interface will be an enhanced and extended version of the existing client OPI and will include all the options available in Personal Agent and PCClient for the end users to manage their accounts. Access to this functionality will be enforced by the service package framework via a new service that will be introduced. User credentials are used for authentication.

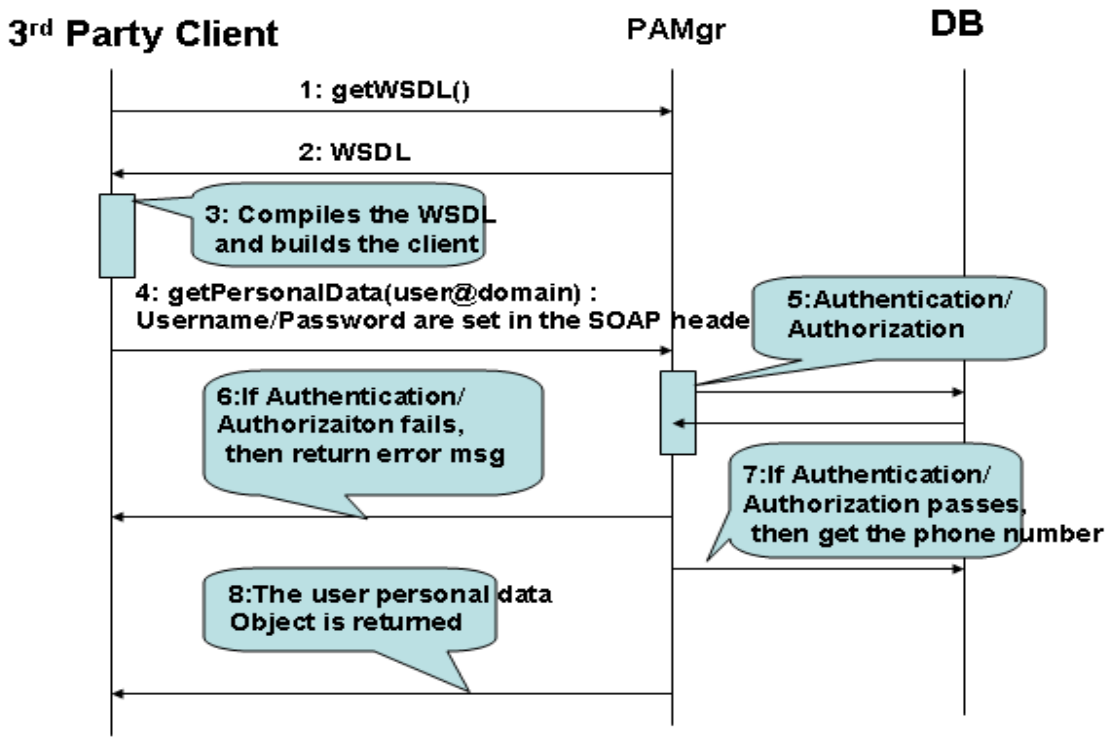
Some of the advantages of Subscriber OPI are as follows:

- Web-Service based API, providing an option for the customers to build their own clients and custom web portals for the end user to manage his account thereby giving the end users a different look and feel.
- This interface can be used to add MCS user management functions into an already existing customer client or web portal thereby removing the need for the end user to learn and use a new application to manage his account.
- The benefits of the current existing Provisioning OPI can all be applied to this interface.



101.2.1 Subscriber OPI Request Flow

The following diagram explains the message flow between a third party client built using Subscriber OPI and the MCS PAMgr. The first two operations are needed only when the third party client is built the first time and when there is a interface change between releases. The rest of the actions take place for every subscriber OPI request.



Steps :

1. Get the latest WSDL document from the PAMgr for the area for which the client is being built. In this case get the UserPersonalData web service WSDL.
2. Generate the client's stubs from the WSDL document. The client stubs have to be compiled before they can be used to access the interface. The detailed steps involved in building a client using the SOPI interface is out of the scope of this document
3. Build the SOAP request by setting the username/password and version number in the header. Get the service locator for the required service and call the method. In this case call the getPersonalData(user@domain).
4. The request comes to the PAMgr/UserPersonalData web service. The respective authentication handler performs the authentication by getting the username and password information from the SOAP message. After successful authentication, the request is forwarded to the respective web service where the authorization check is performed.
5. If authentication or authorization fails, then an error message is returned to the client. The failed attempt is logged.

6. If authentication and authorization passess, then the data is obtained from the DB.
7. The requested information is returned to the client. In this case the user personal data object is returned.

101.2.2 Authentication

The difference between OPI and Subscriber OPI is the authentication process. OPI is used by the provisioning administrator's and credentials of the respective administrator are needed for authentication. Whereas in Subscriber OPI, user credentials i.e. username and password of the user who is using the client built using the Subscriber OPI are needed for authentication.

101.2.3 Authorization

The access to this functionality will be controlled by the new "Subscriber OPI" service that will be introduced as part of this feature. If this service is present in the user's service packages, then the Subscriber OPI requests coming from this user will be allowed to go through. In addition to this service, additional restrictions will be in place to limit the availability of the sub-areas to the users. For ex. if the service "Advanced

In addition to the service enforcement, the subscriber OPI requests coming from users who are inactive i.e. if their status/statusreason is set to "INACTIVE

101.2.4 2.2.4User Operations and Methods

The Subscriber Open Provisioning Interface will have all the operations that are available for the user in PA and PCClient. The user operations are grouped as follows:

- User Personal Information
- User Time Block Groups
- Personalized Call Settings
- Address Book and Search
- Call Screening and Routes
- Service Preferences
- MeetMe Service Data
- Unified Communications Service Data
- Call Logs

The SOPI is a set of different web services, with each web service dealing with a different area of the user operations. Each of the above will be its own web service and will have its own WSDL. This means that if a client wants to access the address book methods then the corresponding addressbook WSDL

has to be used to generate the stubs. This provides maintainability, extensibility and granularity of functionality which can be used to license these services later.

101.2.4.1 User Personal Information

This interface has the methods which can be used to access and manage the user's personal information like email, office phone number, home phone number, etc. These methods will be available for all the user's and are not service package controlled. The UserPesonalData object will have the username, aliases, first name , last name, email, business phone number, home phone number, cell phone number, pager, fax, timezone and locale information. There will be a restriction on the server side which will prevent the modification of username and alias information. First and last names can be modified through this interface. Even though, first and last names can be modified, both of them cannot be null. One of them should be present as it will be used by the IPCM feature to generate the display name. There are certain fields of the user personal data which are synced through the LDAP server. The list of fields that are synced by the LDAP server is provisioned at the domain level. Currently, PA restricts the ability to modify these fields. To maintain the same behavior, there will be a method which will return the fields that are synched by the LDAP server for a user which will enable the clients to make these fields as read only. There will also be a check on the server side which will prevent the modification of these fields through SOPI.

Provisionable Entity: UserPersonalData

WebService Name: PersData

Required ServicePackage Service : None

Method Summary

void	**authenticateUser**(java.lang.String userName, java.lang.String password) This method is used to authenticate the user.
void	**changePassword**(java.lang.String userName, java.lang.String oldPassword, java.lang.String newPassword) This method is used to change the user password.
void	**getUserPersonalData**(java.lang.String userName) This method is used to get the user personal information.
void	**modifyUserPersonalData**(java.lang.String userName, com.nortelnetworks.ims.base.prov.opi.shared.user.UserPersonalData upd) This method is used to modify the user personal information.

User Personal Data	
PEMgr	**UserPersonalDataMgr**
PE	**UserPersonalData**
Method	**Description**
addUserPersonalData	To add the user personal information like email,office phone, home phone etc.
modifyUserPersonalData	To modify the user personal information like email,office phone, home phone etc.
removeUserPersonalData	To remove the user personal information like email,office phone, home phone etc.
getUserPersonalData	To get the user personal information like email,office phone, home phone etc.
Password	
authenticateUser	To authenticate the user
changePassword	To change the user password

101.2.4.2 2.2.4.2TimeZones

Provisionable Entity: TimeZone

WebService Name: TimeZone

Required ServicePackage Service : None

Method Summary	
TimeZone[]	**getAllTimeZones**() Returns all the TimeZones existing in the System

101.2.4.3 Locales

Provisionable Entity: LocaleData

WebService Name: Locale

Required ServicePackage Service : None

Method Summary	
LocaleData[]	**getSystemLocalesList**() Returns all the Locales existing in the System

101.2.4.4 Password Policy

Provisionable Entity: NONE

WebService Name: UserPwd

Required ServicePackage Service : None

Method Summary	
java.lang.String	**getPasswordPolicyDescription**(java.lang.String userName) This method is used to get the password policy description for the user's domain.

101.2.4.5 E911 Location List

Provisionable Entity: LocList

WebService Name: E911Loc

Required ServicePackage Service : None

Method Summary	
LocList	**getLocationList**(long timestamp, boolean forceDownload, java.lang.String domainName) This method is used to retrieve the location list for a particular domain to send to a client.

101.2.4.6 UserPicture

Provisionable Entity: UserPicture

WebService Name: Picture

Required ServicePackage Service : None

This interface has the user picture methods.

Method Summary	
void	**addUserPicture**(java.lang.String userName, UserPicture picture) This method is used to add a picture that is associated with the userName that is passed in
UserPicture	**getUserPicture**(java.lang.String userName) This method is used to retrieve the picture associated with the userName that is passed in
void	**modifyUserPicture**(java.lang.String userName, UserPicture picture) This method is used to modify the picture associated with the userName that is passed in
void	**removeUserPicture**(java.lang.String userName) This method is used to remove the picture associated with the userName that is passed in

101.2.4.7 2.2.4.7User TimeBlocks

This interface has the methods which can be used to access and manage the user's time block groups. These methods will be available for all the user's and are not service package controlled. These time blocks are used by the advanced screening and routing functionality and will only be useful if the user has the "Advanced Screening" service.

Provisionable Entity: TimeBlockGroup

WebService Name: TimeBlock

Required ServicePackage Service : None

Method Summary	
void	**addTimeBlockGroup**(java.lang.String userName, TimeBlockGroup timeBlockGrp) This method is used to create a new TimeBlockGroup with the information provided for the user with username given
void	**addTimeBlockGroups**(java.lang.String userName, TimeBlockGroup[] timeBlockGrps) This method is used to create a new TimeBlockGroup with the information provided for the user with username given

TimeBlockGroup	**getTimeBlockGroupByName**(java.lang.String userName, java.lang.String timeBlockGrpName) This method is used to get the TimeBlockGroup for a user specified by the name provided
TimeBlockGroup[]	**getTimeBlockGroupsByUser**(java.lang.String userName) This method is used to get the TimeBlockGroups for a user
void	**modifyTimeBlockGroup**(java.lang.String userName, java.lang.String timeBlockGrpName, TimeBlockGroup timeBlockGroup) This method is used to modify the timeblock group with the parameters given
void	**removeTimeBlockGroup**(java.lang.String userName, java.lang.String timeBlockGrpName) This method is used to delete a TimeBlockGroup idenfied by the name provided for the user whose name is given
void	**removeTimeBlockGroups**(java.lang.String userName) This method is used to delete all the timeblock groups associated to the user whose user name is given

101.2.4.8 Personalized Call Settings

This interface has the methods which can be used to access and manage the user's personalized call notes like subjects, reasons, and personalized presence notes. These methods will be available for all the user's and are not service package controlled.

Provisionable Entity: UserData

WebService Name: UserData

Required ServicePackage Service : None

Method Summary	
java.lang.String[]	**getNotesByUserName**(java.lang.String userName) This method is used to retrieve the list of notes associated to the user whose username is being passed in
java.lang.String[]	**getRejectReasonsByUserName**(java.lang.String userName) This method is used to retrieve the list of reasons associated to the user whose username is being passed in
java.lang.String[]	**getSubjectsByUserName**(java.lang.String userName) This method is used to retrieve the list of subjects associated to the user whose username is being passed in

UserData	**getUserData**(java.lang.String userName) This method is used to retrieve the UserData associated to the user whose username is passed in
void	**modifyUserData**(java.lang.String userName, UserData userData) This method is used to update the UserData associated to the user whose username is given with the UserData information being passed in
void	**modifyUserNotes**(java.lang.String userName, java.lang.String[] notes) This method is used to update the notes associated to the user whose username is given with the notes list information being passed in
void	**modifyUserReasons**(java.lang.String userName, java.lang.String[] reasons) This method is used to update the reasons associated to the user whose username is given with the reasons list information being passed in
void	**modifyUserSubjects**(java.lang.String userName, java.lang.String[] subjects) This method is used to update the subjects associated to the user whose username is given with the subjects list information being passed in
void	**removeAllCallSubjects**(java.lang.String userName) This method is used to remove all the subjects associated to the user whose username is passed in
void	**removeAllRejectReasons**(java.lang.String userName) This method is used to remove all the reasons associated to the user whose username is passed in
void	**removeAllUserNotes**(java.lang.String userName) This method is used to remove all the notes associated to the user whose username is passed in
void	**removeUserData**(java.lang.String userName) method is used to remove the UserData associated to the user whose username is passed in

101.2.4.9 Address Book

This interface has the methods which can be used to access and manage the address book and directory information of a user.

Provisionable Entity: AddressBookEntry

WebService Name: AddrBook

Required ServicePackage Service : None

Note: Although no service is required for the address book methods, the number of address book entries that the user can have and the ability to have buddies is controlled by the Maximum Number of Address Book entries and the Presence service respectively.

Method Summary

void	**addAddressBookEntries**(java.lang.String userName, AddressBookEntry[] addrBookEntries) This method is used to create a new addressbook entry for the user specified
void	**addAddressBookEntry**(java.lang.String userName, AddressBookEntry addrBookEntry) This method is used to create a new addressbook entry for the user specified
AddressBookEntry[]	**getAddressBook**(java.lang.String userName) This method is used to get the addressbook for the user whose name is passed in.
AddressBookEntry	**getAddressBookEntry**(java.lang.String userName, java.lang.String nickName) This method is used to get an addressbook entry for the user whose name is passed in and identified by the nic++kname provided.The addressbook retrieved contains information on the uses buddies, banned users and groups.
FullAddressBookEntry[]	**getAddressBookWithPhoto**(java.lang.String userName)
java.lang.String[]	**getBuddies**(java.lang.String userName) This method is used to get the buddies for the user with user name userName.
FullAddressBookEntry	**getFullAddressBookEntry**(java.lang.String userName, java.lang.String nickName)
AddressBookEntry[]	**getLightWeightAddressBook**(java.lang.String userName)
void	**makeBuddy**(java.lang.String userName, java.lang.String buddyName)
void	**modifyAddressBookEntries**(java.lang.String userName, java.lang.String[] nickName, AddressBookEntry[] addrBookEntry) This method is used to update an addressbook entry for the user specified and identified by the nickname provided

void	**modifyAddressBookEntry**(java.lang.String userName, java.lang.String nickName, AddressBookEntry addrBookEntry) This method is used to update an addressbook entry for the user specified and identified by the nickname provided
void	**removeAddressBook**(java.lang.String[] userNames) This method is used to delete addressbook for the user identified by the username(s) provided
void	**removeAddressBookEntries**(java.lang.String userName, java.lang.String[] nickName) This method is used to delete multiple addressbook entry identified by the nickname provided for the user whose username is specified
void	**removeAddressBookEntry**(java.lang.String userName, java.lang.String nickName) This method is used to delete an addressbook entry identified by the nickname provided for the user whose username is specified
void	**removeBuddy**(java.lang.String userName, java.lang.String buddyName) This method is used to remove an addressbook entry identified as a buddy in this user's addressbook from the buddy list and make his a normal entry

101.2.4.10 2.2.4.10 AddressBook Groups

Provisionable Entity: None

WebService Name: AbGroup

Required ServicePackage Service : None

Method Summary

void	**addAddressBookGroup**(java.lang.String userName, java.lang.String groupName) This method is used to add a group to the user whose user name is given, the group name can be anything from Family,Friends,Work etc.
void	**addAddressBookGroups**(java.lang.String userName, java.lang.String[] groupNames)
void	**addUsersToAddressBook**(java.lang.String userName, java.lang.String[] users) This method is used to add all the users given to this user's address book.

java.lang.String[]	**getAddressBookGroups**(java.lang.String userName) This method is used to get all the groups associated to a user in his address book which are used for adding entires to his address book
void	**modifyAddressBookGroups**(java.lang.String userName, java.lang.String[] groupName) This method is used to add more groups to the user whose user name is given, the method verifies if there is a group in this list already existing, if so does not add it, but if it does not, it is added to the groups list that the user has
void	**removeAddressBookGroup**(java.lang.String userName, java.lang.String groupName) This method is used to remove an addressbook group identified by the groupname given from this user's addressbook
void	**renameAddressBookGroup**(java.lang.String userName, java.lang.String groupName, java.lang.String updatedGroupName)

101.2.4.11 Global Address Book Search

The search Global Address Book functions are included in this interface.

Provisionable Entity: `FullAddressBookEntry`

WebService Name: GABSearch

Required ServicePackage Service : None

Method Summary	
FullAddressBookEntry[]	**searchGABByFirstName**(java.lang.String userName, java.lang.String firstName) This method can be used to obtain the user's in the global address book with the passed in search criteria.
FullAddressBookEntry[]	**searchGABByLastName**(java.lang.String userName, java.lang.String lastName) This method can be used to obtain the user's in the global address book with the passed in search criteria.
FullAddressBookEntry[]	**searchGABByName**(java.lang.String userName, java.lang.String name) This method can be used to obtain the user's in the global address book with the passed in search criteria.

FullAddressBookEntry[]	**searchGABByPhoneNumber**(java.lang.String userName, java.lang.String phoneNumber) This method can be used to obtain the user's in the global address book with the passed in search criteria.
FullAddressBookEntry[]	**searchGABByUserName**(java.lang.String userName, java.lang.String searchUserName) This method can be used to obtain the user's in the global address book with the passed in search criteria.

101.2.4.12 Call Screening and Routes

This interface has the methods which can be used to access and manage the user routes information which is used to generate the CPL of a user. These methods will be controlled by the "**Advanced Screening**" service. If the user does not have this service in his service package, then he will not be able to execute these methods

Provisionable Entity: Route

WebService Name: Routes

Required ServicePackage Service : AdvancedScreening and Routing for advanced routing options. Instant Messaging for the IM Routing options. Client Collaboration/WebPush service and/or parm for the "Send WebPage" option.

Method Summary

void	**activateRoutes**(java.lang.String userName, java.lang.String[] routeNames) This method is used to set the status of the routes specified in the input list as Active.
void	**addRoute**(java.lang.String userName, Route route) This method is used to create a new RouteList with the information provided for the user with username given
void	**addRoutes**(java.lang.String userName, Route[] routes) This method is used to create a new RouteList with the information provided for the user with username given
void	**deactivateRoutes**(java.lang.String userName, java.lang.String[] routeNames) This method is used to set the status of the routes specified in the input list as Inactive.
java.lang.String[]	**getAllRouteParmNames**() This method return the valid names to be used in the parms attribute of the route.

Route	**getRoute**(java.lang.String userName, java.lang.String routeName) This method is used to get the Route with the name of the route specified and for the user identified by the username provided.
java.lang.String[]	**getRouteNames**(java.lang.String userName) This method is used to get the names of the routes for the user with the given userName
Route[]	**getRoutes**(java.lang.String userName) This method is used to get all the routes for the user with the given user name.
void	**modifyRoute**(java.lang.String userName, java.lang.String routeName, Route newRoute) This method is used to modify a Route for the user with name given with the route information provided
void	**removeAllRoutes**(java.lang.String userName) This method is used to delete all routes identified by the username of the user to whom these routes belong.
void	**removeRoute**(java.lang.String userName, java.lang.String routeName) This method is used to delete a Route identified by the route name and the username.
void	**reorderRoutes**(java.lang.String userName, java.lang.String[] routeNames) This method reorders the routes specified in the input.
void	**setActiveRoutes**(java.lang.String userName, java.lang.String[] routeNames) This method sets only the routes specified in the input to active status and resets the status of all the remaining routes (if any) to inactive.

101.2.4.13 Service Preferences

This interface has the methods which can be used to access and manage the service package information of a user. These methods will be controlled by the different services present in the user's service package. For ex. If the user does not have "Presence" in his package, then he will not be able to set the user preferences for that service. The banlist methods are controlled by the "Presence" service.

Provisionable Entity: ServicePackage, Service and DetailedService

WebService Name: UserPref

Required ServicePackage Service : None. But, the user can only access the preferences for the services present in his service package.

Method Summary	
DetailedService[]	**getAllDetailedUserPreferences**(java.lang.String userName) This method is used to obtain the user preferences for all the services that he has.
Service[]	**getAllUserPreferences**(java.lang.String userName) This method is used to obtain the user preferences for all the services that he has.
ServicePackage	**getUserServicePackage**(java.lang.String userName) This method is used to obtain the ServicePackage object to which the user belongs to.
void	**modifyAllUserPreferences**(java.lang.String userName, com.nortelnetworks.ims.base.prov.opi.shared.Service[] services) This method is used to add/modify user preferences .This method should only be used when adding/modifying the user preferences for all the services that he has.
void	**modifyUserPreferences**(java.lang.String userName, com.nortelnetworks.ims.base.prov.opi.shared.Service service) This method is used to add/modify user preferences for a specific service.
void	**removeAllUserPreferences**(java.lang.String userName) Thismethod is used to remove all the user preferences

101.2.4.14 MeetMe Service Data

This interface has the methods which can be used to access the meetme service data of a user. These methods will be controlled by the "**Meet Me Conferencing**" service. If the user does not have this service in his service package, then he will not be able to execute these methods. In addition to that if the MeetMe service(MAS) is not properly configured for the user's domain, then these methods will not be executed and an error message will be returned.

Provisionable Entity: MeetMeConfData

WebService Name: MeetMe

Required ServicePackage Service : Meet Me Conferencing.

If the MeetMe service(MAS) is not properly configured for the user's domain, then these methods will not be executed and an error message is returned.

Method Summary	
MeetMeConfData	**addMeetMeConfUser**(java.lang.String userName, MeetMeConfData meetmeConfData) This method is used to add a new MeetMe conf user.
MeetMeConfData	**getMeetMeConfData**(java.lang.String userName) This method is used to retrieve MeetMe Conf data for a particular user.
MeetMeConfData	**modifyMeetMeConfUser**(java.lang.String userName, MeetMeConfData meetmeConfData) This method is used to update an existing MeetMe conf user.
void	**removeMeetMeConfUser**(java.lang.String userName) This method is used to delete an existing MeetMe conf user from the system.

101.2.4.15 Unified Communications Service Data

This interface has the methods which can be used to access the unified communications service data of a user. These methods will be controlled by the "**Unified Communications**" service. If the user does not have this service in his service package, then he will not be able to execute these methods. In addition to that if the Unified Communications(MAS) service is not properly configured for the user's domain, then these methods will not be executed and an error message will be returned.

Provisionable Entity: UCUserData

WebService Name: UC

Required ServicePackage Service : Unified Communications

If the Unified Communications service(MAS) is not properly configured for the user's domain, then these methods will not be executed and an error message is returned.

Method Summary	
void	**addSecondaryUCAutoID**(java.lang.String userName, UCAutoIDData autoIDData) This method is used to add the auto id data for an UC user in the associated Media Application Server (MAS) database.
UCUserData	**addUCUser**(java.lang.String userName, UCUserData ucUserdata) This method is used to add the user preferences relevant to UC service in the associated Media Application Server (MAS) database.

java.lang.String	**getActiveGreeting**(java.lang.String userName) This method is used to get the active greeting for an UC user.
long	**getPasswordExpiryTime**(java.lang.String userName) This method is used to retrieve the time the user's password will expire.
UCAutoIDData	**getPrimaryUCAutoID**(java.lang.String userName) This method is used to get the auto id data for which the address is same as the sip user id of the UC user in the associated Media Application Server (MAS) database.
UCAutoIDData[]	**getSecondaryUCAutoIDs**(java.lang.String userName) This method is used to get the secondary auto id data for an UC user in the associated Media Application Server (MAS) database.
long	**getTemporaryGreetingExpiryTime**(java.lang.String userNam e) This method is used to retrieve the time the temporary greeting will expire.
UCGreetingData[]	**getUCGreetings**(java.lang.String userName) This method is used to get the greetings data for an UC user in the associated Media Application Server (MAS) database.
UCUserData	**getUCUser**(java.lang.String userName) This method is used to retrieve the preferences for an UC user from the associated Media Application Server (MAS) database.
java.lang.String[]	**getValidAccountStatus**() This method returns all the valid strings representing account status .
java.lang.String[]	**getValidAutoReadValues**() This method returns all the valid values for the auto read field (UCUserData)
java.lang.String[]	**getValidEmailAttachmentTypes**() This method returns all the valid email attachment types.
java.lang.String[]	**getValidGreetingKeys**() This method returns all the valid greeting keys that are used to construct the greeting data.
java.lang.String[]	**getValidGreetingNames**() This method returns all the valid greeting names.
java.lang.String[]	**getValidPrimaryAutoLoginValues**() This method returns all the valid values for the auto login field (UCAutoIDData)
java.lang.String[]	**getValidSecondaryAutoLoginValues**() This method returns all the valid values for the auto login field (UCAutoIDData)
void	**modifySecondaryUCAutoID**(java.lang.String userName, UCAutoIDData autoIDData) This method is used to modify the secondary auto id data for an UC user in the associated Media Application Server (MAS) database.

UCUserData	**modifyUCUser**(java.lang.String userName, UCUserData data) This method is used to update the preferences relevant to UC service in the associated Media Application Server (MAS) database.
void	**removeSecondaryUCAutoID**(java.lang.String userName, java.lang.String autoIDAddress) This method is used to remove the secondary auto id data for an UC user in the associated Media Application Server (MAS) database.
void	**removeUCUser**(java.lang.String userName) This method is used to delete the preferences for an UC user from the associated Media Application Server (MAS) database.
void	**setActiveGreeting**(java.lang.String userName, java.lang.String greetingName) This method is used to mark a greeting as active for an UC user in the associated Media Application Server (MAS) database.
void	**setPrimaryUCAutoID**(java.lang.String userName, UCAutoIDData autoIDData) This method is used to add the primary sip user id as the auto id address for an UC user in the associated Media Application Server (MAS) database.
void	**setTemporaryGreeting**(java.lang.String userName, long timeExpires) This method is used to set the expiry time interval for a temporary greeting for an UC user in the associated Media Application Server (MAS) database.
void	**setUCGreeting**(java.lang.String userName, UCGreetingData greetingData) This method is used to update/add a greeting data for an UC user in the associated Media Application Server (MAS) database.

101.2.4.16 Call Logs

This interface has the methods which can be used to access the call log information of a user. These methods will be controlled by the "**Network Call Logs**" service. If the user does not have this service in his service package, then he will not be able to execute these methods.

Provisionable Entity: CallLog

WebService Name: CallLog

Required ServicePackage Service : NetworkCall Logs

Method Summary

void	**deleteCallLogs**(java.lang.String username, java.lang.String[] callIds)
CallLog[]	**getCallLogs**(java.lang.String username)
CallLog[]	**getIncomingCallLogs**(java.lang.String username)
CallLog[]	**getOutgoingCallLogs**(java.lang.String username)

101.2.4.17 Banned Users

Provisionable Entity: None

WebService Name: BanUser

Required ServicePackage Service : None

Method Summary	
void	**addBannedUser**(java.lang.String userName, java.lang.String bannedUserName)
void	**addBannedUsers**(java.lang.String userName, java.lang.String[] bannedUserNames)
java.lang.String[]	**getBannedUsers**(java.lang.String userName) This method is used to get all the users banned from subscribing to this user's presence information from the ban list in the addressbook.
void	**modifyBannedUser**(java.lang.String userName, java.lang.String bannedUserName) This method is used to add a user to the ban list of a user's addressbook which would prevent the banned user from subscribing to this user's presence information
void	**removeAllBannedUsers**(java.lang.String userName) This method is used to remove all users banned from subscribing to this user's presence information from the ban list in the addressbook.
void	**removeBannedUser**(java.lang.String userName, java.lang.String bannedUserName)

101.2.4.18 AssistantUser Mgr

Provisionable Entity: None

WebService Name: AssUser

Required ServicePackage Service : Assistant Console

Method Summary	
java.lang.String[]	**getAssistedUsers**(java.lang.String userName)

101.2.4.19 ClickToCall

Provisionable Entity: None

WebService Name: CTCall

Required ServicePackage Service : None

Method Summary	
void	**clickToCall**(java.lang.String userName, java.lang.String password, java.lang.String ctcFromParty, java.lang.String ctcToParty)

101.2.4.20 I200x

Provisionable Entity: None

WebService Name: i200x

Required ServicePackage Service : None

Method Summary	
void	**logoutUserFromDevice**(java.lang.String userName, java.lang.String Macaddress)

101.2.4.21 SOPI Version

Provisionable Entity: None

WebService Name: SOPIVersion

Required ServicePackage Service : None

Method Summary	
java.lang.String	**getCurrentSOPIVersion**()
java.lang.String[]	**getSupportedSOPIVersions**()

101.2.5 Logging of Subscriber OPI requests

All failed authentication and authorization subscriber OPI requests will be logged.

101.2.6 Release Information

Since this is the first official release for this interface, all the existing user management functions available in PA and PCClient will be included in the MCS4.1 Subscriber OPI specification. Any new functionality or methods introduced by any other features in this release have to be included in this interface as part of the respective feature work. The subscriber OPI will be forward compatible with the PAmgr for one official release. This means that the MCS 4.1/09 subscriber OPI will be supported by the MCS 10 PAmgr, if 10 is our next official release.

101.2.7 Deploy Information

A new WAR called Subscriber OPI or SOPI will be created to place these new web services. This war will be packaged as part of the PA network element and will be deployed as part of the PAMgr. Since PROV mgr is a super set of all these web services, when PROV is deployed, PA is also deployed and is installed on a different virtual server. Please refer to FTR460 for more information on this.

101.3 Hardware Requirements or Dependencies

None

101.4 Software Requirements or Dependencies

None.

101.5 Limitations and restrictions

Password Change from Subscriber OPI. If a user changes his password from this interface, the change will be immediate and the subsequent requests should include the new password in the header. This is different from the behavior in PA wherein the new password takes effect when the user log's in the next time.

101.6 Interactions

- The existing ClientOPI interface will be supported in two forward releases starting from 4.1/09. For ex. if 10.0 and 11.0 are the next two releases after 4.1/09, the client OPI interface will be deprecated in this release and will be removed in 11.0. The client OPI has to be supported in 10.0 for backward compatibility issues with 4.1/09 PCClient. This would also mean that the PCClient which is currently using the client OPI interface will have to be changed in 10.0 to use the new SOPI interface.
- Refer to FTR460 for information regarding the SSL support for these web services.
- Watchers list methods are not supported by this interface.

101.7 Glossary

Term	Description
Subscriber OPI	Subscriber Open Provisioning Interface
WSDL	Web Services Description Language
WAR	Web Application Archive
CPL	Call Processing Language

102: Functional Description (FN): A00009830

102.1 Feature name and Feature ID

A00009830 - Complete Re-IP Support

102.2 Background

The requirement for this feature stems from two distinct needs in the MCP marketplace. First, since the install of the system is a lengthy and time consuming process there is a need to shorten the “order to delivery” time in order to make our supply chain more responsive to orders that it receives. To do this the concept of pre-staging of software is used. Pre-staging allows software to be completely installed on the system prior to receiving a customer order. Once an order is placed, the customer specific addressing is added and the system can then be shipped. This feature does not change the overall time to install and deliver a system, but it does reduce the time period from “order to delivery”.

Pre-Staging software is defined as the ability to assemble and load the product before customer specific information is received. This is differentiated from staging of software because it is done with generic customer information, where as staging is typically done once the order is received and the specific customer information can be used in the staging process.

The second need for this feature stems from the fact that customer networks are an ever changing entity. In order to provide the best support/customer service to our customer base, the ability to adapt to these network changes is important. This feature allows the changing of IP addresses to accommodate network topology changes without requiring a reload or redeploy of the MCP product.

102.3 Overview

This feature enables the ability to change various server identification parameters, such as country, time-zone, and IP address, while maintaining the implemented system OS hardening aspects. This feature does not require re-loading software from CD.

In addition this feature provides a central place in the management GUI to change the IP address for MCS software components that are deployed on a box that is Re-IPed. It will not be required to undeploy or re-deploy the MCS software when changing the box IP address.

This feature also provides a mechanism for all the provisioning data on the Provisioning Client to be changed automatically when a particular box is Re-IPed.

This feature is not a procedure to migrate MCP software to a different server nor is it a procedure to add or remove servers to the network. Any topology change to the network is not covered by this feature, other than Re-IP of servers.

102.4 Feature Description

The Re-IP feature can be divided into two distinct logical functions.

1. Re-IP of MCS servers.
2. Re-IP of MCS software components.

102.4.1 Re-IP of MCS Server

The MCS components run on servers with several different operating systems:

1. The core services run on the Sun Solaris and the Linux OS. This includes the System Manager, Accounting Manager, IP Client Manager, Database, Provisioning Manager and Session Manager. This feature will enable the Re-IP of these servers.
2. The RTP Media Portal runs on Red Hat Linux OS. This feature will enable the Re-IP of these servers.
3. The Media Servers and UAS PRI Gateway run on the Windows 2000 OS. These servers are not managed by the System Manager and are not Re-IPed under this feature.
4. Re-IP of third party servers is not a part of this feature.

Servers supported by this feature will be Re-IPed using an OS specific script which is required to run on each of the servers being Re-IPed. All MCS software components running on the server should be stopped before starting the Re-IP process.

All data to be changed will be required at the beginning of the script and can be provided interactively or via a file. A confirmation message will be displayed at the end for the user to accept or reject the changes and the user has the option to back out at this time and no changes will be done.

If the user chooses to proceed, the script will run and the machine will be Re-IPed. After the script has completed, the server will require a reboot.

102.4.1.1 Re-IP Sun Solaris System

This feature enables the ability to change the Sun Solaris country and timezone parameters and all IP addresses. It will maintain the implemented system OS hardening aspects. This feature does not require re-loading software from CD.

102.4.1.2 Re-IP Linux System

This feature enables the ability to change the country and timezone parameters and all IP addresses on Linux servers for core components and RTP Media Portal. It will maintain the implemented system OS hardening aspects. This feature does not require re-loading software from CD.

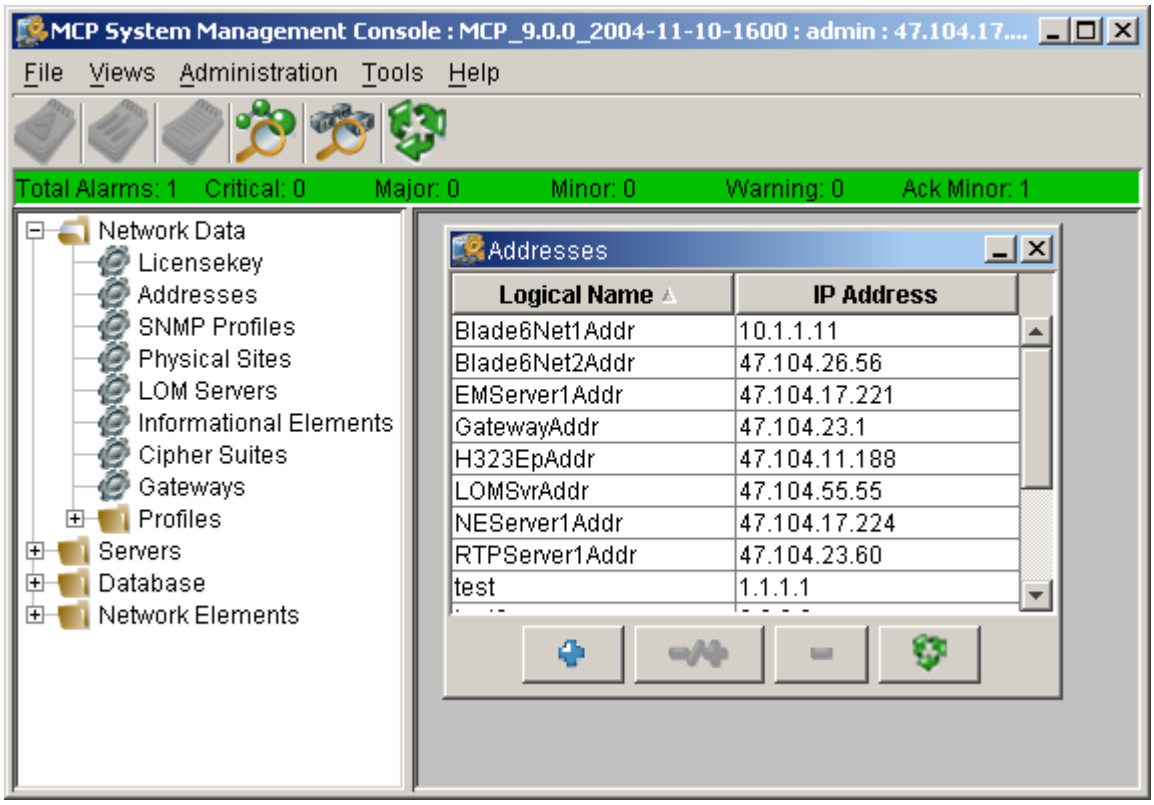
102.4.2 Re-IP of MCS Software Components

The MCP software components can be divided into three broad categories based on their interactions with the System Manager:

1. Managed: The System Manager manages the core components of the MCS solution, such as the Accounting Manager, IP Client Manager, Database, Provisioning Manager and Session Manager.
2. Monitored: Some components may not be deployed by the System Manager but may just be monitored. These components may or may not be running on a server where Re-IP is supported.
3. Informational: Some components are neither managed nor monitored by the System Manager. The System Manager is just aware of the IP address of these components.

This feature provides an Address Table (refer to Figure 1) which is a central location in the System Manager for all IP addresses in the network. Any software component that falls outside the scope of Managed, Monitored, or Informational will not be listed in the Address Table and is not covered by this feature. A System Administrator with sufficient privileges can add, edit, or delete entries in the Address Table via a script or the System Manager GUI.

Figure 1: Address Table



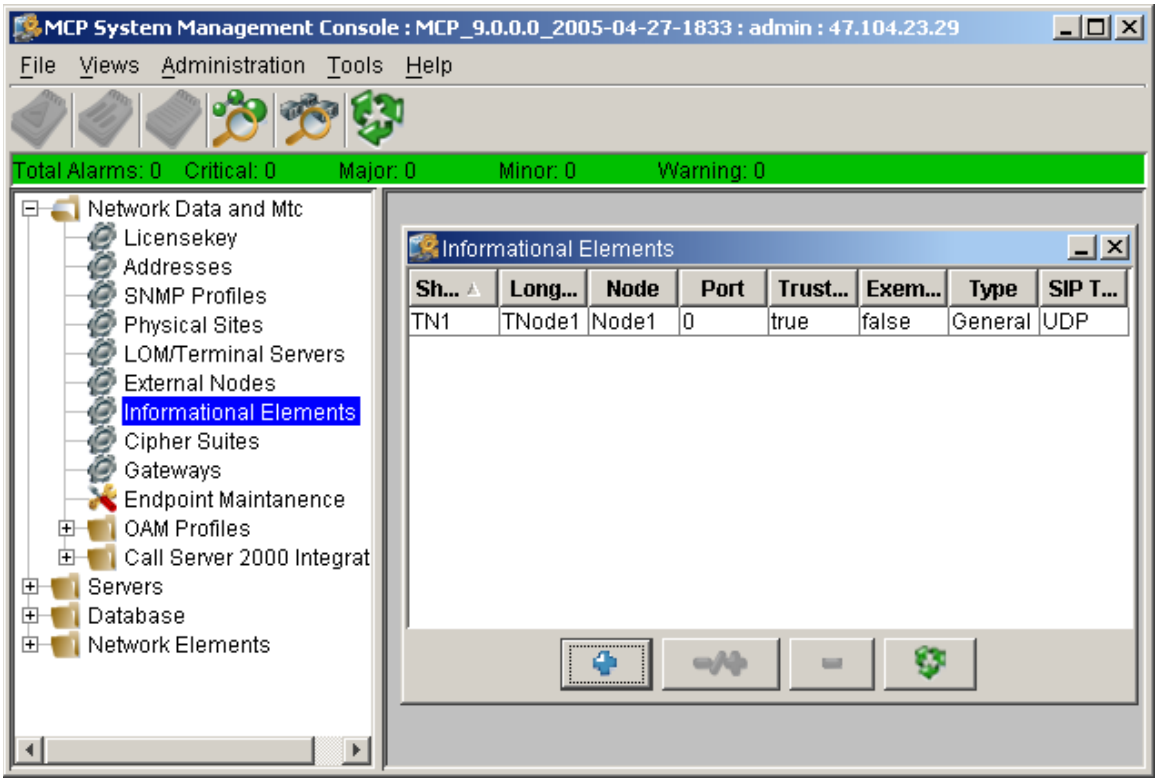
When adding, editing, or deleting an IP address, a confirmation message is displayed before the settings are applied to the system. The address change is then applied to all MCS components managed by the System Manager.

The existing Third Party Trusted Devices configuration service is being changed to provide type information.The new service is called Informational Element service (refer to Figure 2). The provisioning system will use this configuration service for Gateway, Terminal Server, Pooled Entity and LDAP provisioning. The following OMI methods are added for adding, updating, deleting and getting the list of informational elements:

- public RuntimeResult addInfoElement(InfoElementData ieData) throws RemoteException, RequestException;
- public RuntimeResult deleteInfoElement(InfoElementNaturalKey ieKey) throws RemoteException, RequestException;
- public RuntimeResult updateInfoElement(InfoElementData ieData, InfoElementNaturalKey ieKey) throws RemoteException, RequestException;
- public InfoElementData[] getInfoElementList() throws RemoteException, RequestException;

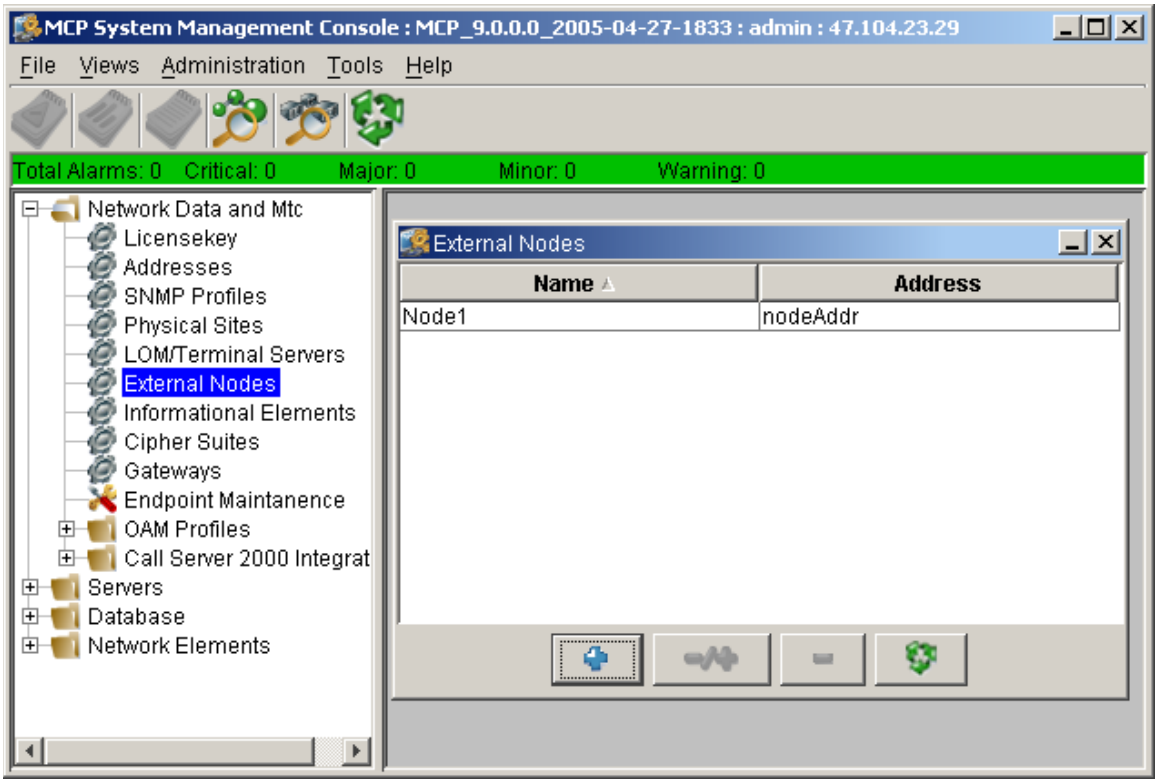
- public String[] getInfoElementTypes() throws RemoteException, RequestException;

Figure 2: Informational Element Service



A new configuration service called External Nodes (refer to Figure 3) is added so that multiple Informational Elements can be added with same IPAddress and different ports.

Figure 3: External Nodes



102.4.2.1 Pre-Staged System Re-IP

When Re-IPing a pre-staged system, first Re-IP all the servers as described in section Re-IP of MCS Server3.1.1. Once the servers are inservice, there are two ways of Re-IPing the MCS components.

1. Run a script on the server that will be running the System Manager and provide the IP addresses for all components. After the changes have been applied, start the System Manager. All managed components can then be started.
2. Run a script on the server that will be running the System Manager and provide only the IP addresses of the System Manager server and the Database server. Apply changes and start the System Manager. Once the System Manager is up, change the individual IP addresses from the System Manager GUI and apply the changes. Then start the remaining MCS components.

102.4.2.2 In Service System Re-IP

In general the following steps will be required to Re-IP a server running a managed MCS component:

1. Using the System Manger GUI, stop all MCS components running on the server to be Re-IPed.
2. Run the Re-IP script on the server and restart the server.
3. Using the System Manager GUI, change the address of the server from the old IP address to the new IP address.
4. Restart all MCS components on the server.

There are exceptions to the above where the System Manager and the database server are involved. These exceptions are listed below.

102.4.2.2.1 Re-IP System Manager Server

The steps necessary to Re-IP the server running the System Manager are as follows:

1. Using the System Manger GUI, stop all MCS components other than the System Manager running on the server.
2. From the command line on the server, stop the System Manager.
3. Run the Re-IP script on the server and restart.
4. Restart the System Manager. Then using the System Manager GUI, restart any other MCS components assigned to the server.

102.4.2.2.2 Re-IP Database Server

The steps necessary to Re-IP the server running the database are as follows:

1. Using the System Manager GUI change the IP address of the server running the database.
2. On the database server, stop the database process.
3. Run the Re-IP script on the database server and restart.
4. Restart the database.

In the case where database replication is enabled, the primary and secondary database must be reconfigured to allow replication from the new IP address. A script is provided to be run on the Oracle servers after the servers have been Re-IPed. This script will make the necessary configuration changes to Oracle in order to continue database replication.

102.4.2.2.3 Re-IP MCS components which are deployed in fault tolerance mode

If a particular component is deployed in a fault tolerant mode, the component deployed on the server being Re-IPed should be made offline, so that the other component instance becomes active.

Once the peer instance has become active, the procedure is the same as described in section In Service System Re-IP 3.1.2.2.

102.4.3 MOPs

Detailed MOPs are provided as part of the feature for each of the following cases:

- **Pre-Staged System Re-IP:**
  - — SUN Servers N240 AC/DC / V100 / T140X running Session Manager, System Manager, Accounting Manager, Provisioning Manager, IP Client Manager, H.323 and Database.
  - — IBM BladeCenter / IBM x306 running RTP Media Portal on Linux.
- **In-Service System Re-IP:**
  - — SUN Servers N240 AC/DC / V100 / T140X running Session Manager, System Manager, Accounting Manager, Provisioning Manager, IP Client Manager, H.323 and Database.
  - — IBM BladeCenter / IBM x306 running RTP Media Portal on Linux.

The in-service system Re-IP will differ in steps from the Pre-Staged Re-IP. MOPs will be written to cover all the following scenarios.

1. Changing customer addresses on entire system.
2. Changing the customer addresses on one or more resources (i.e. gateways, RTP Media Portal)
3. Changing the customer addresses on one or more Session Managers.
4. Changing the customer addresses on one or more Database Servers.
5. Changing the customer addresses of one or more Provisioning Managers.
6. Changing the customer addresses of one or more IP Client Managers.
7. Changing the customer addresses of one or more System Manager / Accounting Managers.
8. Changing the customer addresses of one or more H.323 Servers.

- **OPI/BPT Script Updates:**

  This MOP will describe in detail which OPI methods have been obsoleted and how existing scripts should be updated to utilize the new methods. No existing functionality will be lost.

102.5 Provisioning System Changes

The data on the Provisioning client that uses any IP address will be changed to use the logical names for the addresses or the NE's (if it is NE specific).

The areas identified for change are discussed in the following sections. DB upgrade scripts are written to handle each of these changes for a 3.x to 4.1 and 4.0 to 4.1 system upgrade.

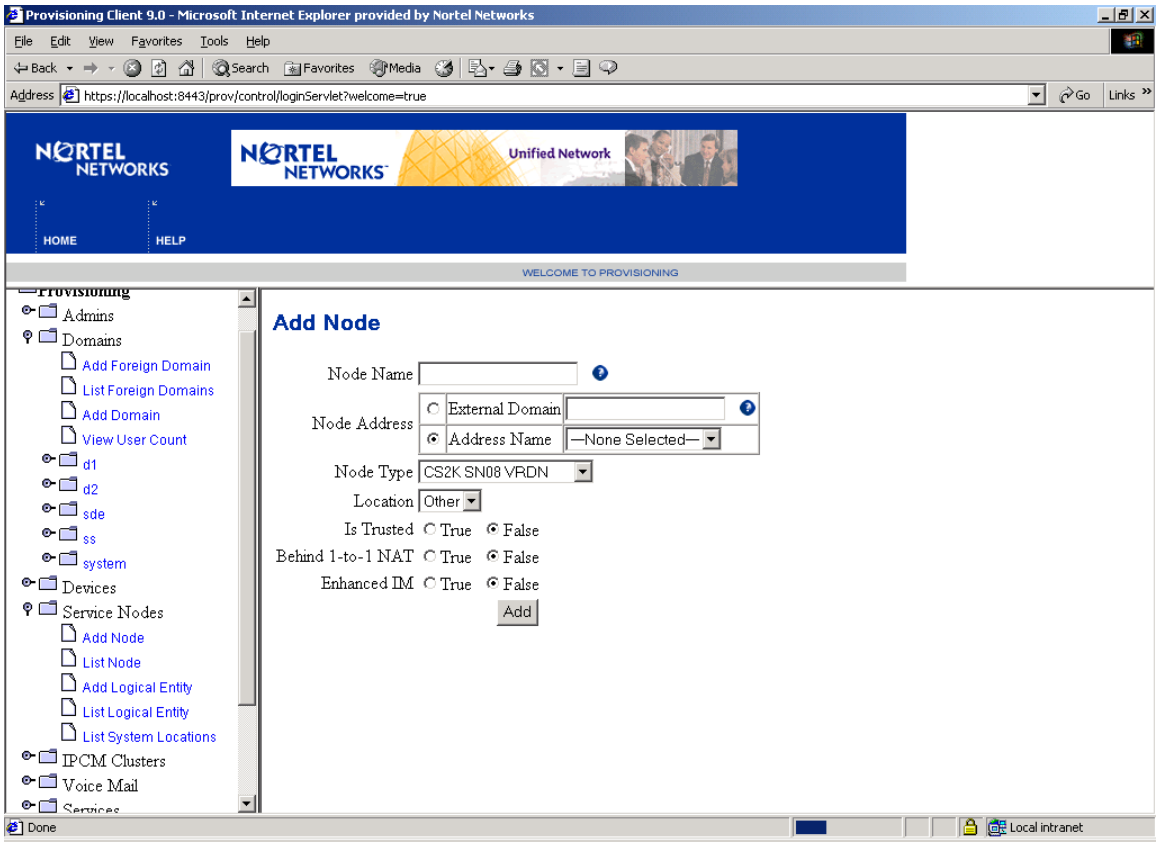
102.5.1 Service Node Provisioning

This feature creates a new menu item under the System level called Service Nodes. A Service Node is defined as any network element which provides a service. Examples include protocol gateways, conference servers, voicemail servers, etc. Attributes such as location, trust status, etc. are associated with each service node. A logical node consists of one or more service nodes. Each service node it contains may have additional system or user defined parameters (e.g. trkgrp) associated with it that affect the service offered by the service node.

A new Right “Node Provisioning” (NODE) is being added. Only admins with this right would be able to manipulate Nodes.

The following shows what the new provisioning page for adding a service node to the system looks like.

Figure 4: Add Service Node



The Add Node page allows the administrator to add a GW, a MAS server, or any third party box as well as provide the necessary attributes such as location and node type that pertain to that box.

The node name is an identifier for the node and has a maximum length of 30 characters. Only alpha numeric and _ chars are allowed.

The External Domain / Address Name fields are mutually exclusive and only one can be enetered.

Under normal circumstances, only the Address Name field should be used. This is a drop down of names of the following elements on the System Manager:
a MAS Server, an Audio Code Gateway, an H323 Gatekeeper, or an Informational Element of type General or Gateway or Pooled Media Resource.

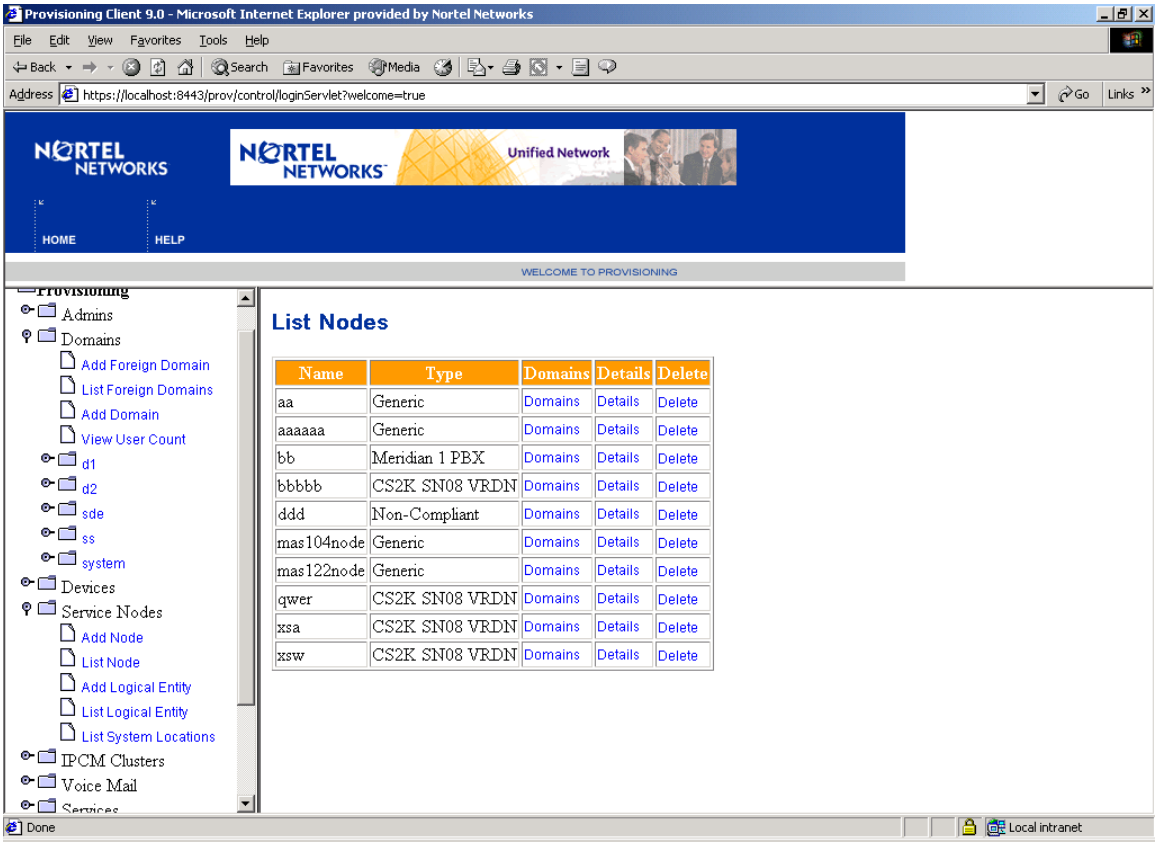
The External Domain field is available in case there is an address that does not have an IP. At this point this is used during upgrades where if the host field on the gateway or the route on the pooled entity cannot be parsed properly, we put the entire route in this field. That ways the calls will still work. A log is generated for all these types and the customer is suggested to fix their provisioning data. No data available in this field is validated and the data is not reipable.

If the customer chooses to add an IP here, and use it instead of the right way of adding it on the SM and then use from pull down, then this data would not be re-ipable.

Node Type: This is the old Gateway Type. The Description for Non-Compliant Gateway and Generic Gateway ahave been changed to Non-Compliant and Generic, so they can be used for other servers.

The following figure shows the ‘List Node’ screen.

Figure 5: List Node



Once the administrator has added the physical nodes, the node can be assigned to root domains. Only after the nodes are assigned, the domains can use those to create gateway routes or ERLs or Assign to Routable Services.

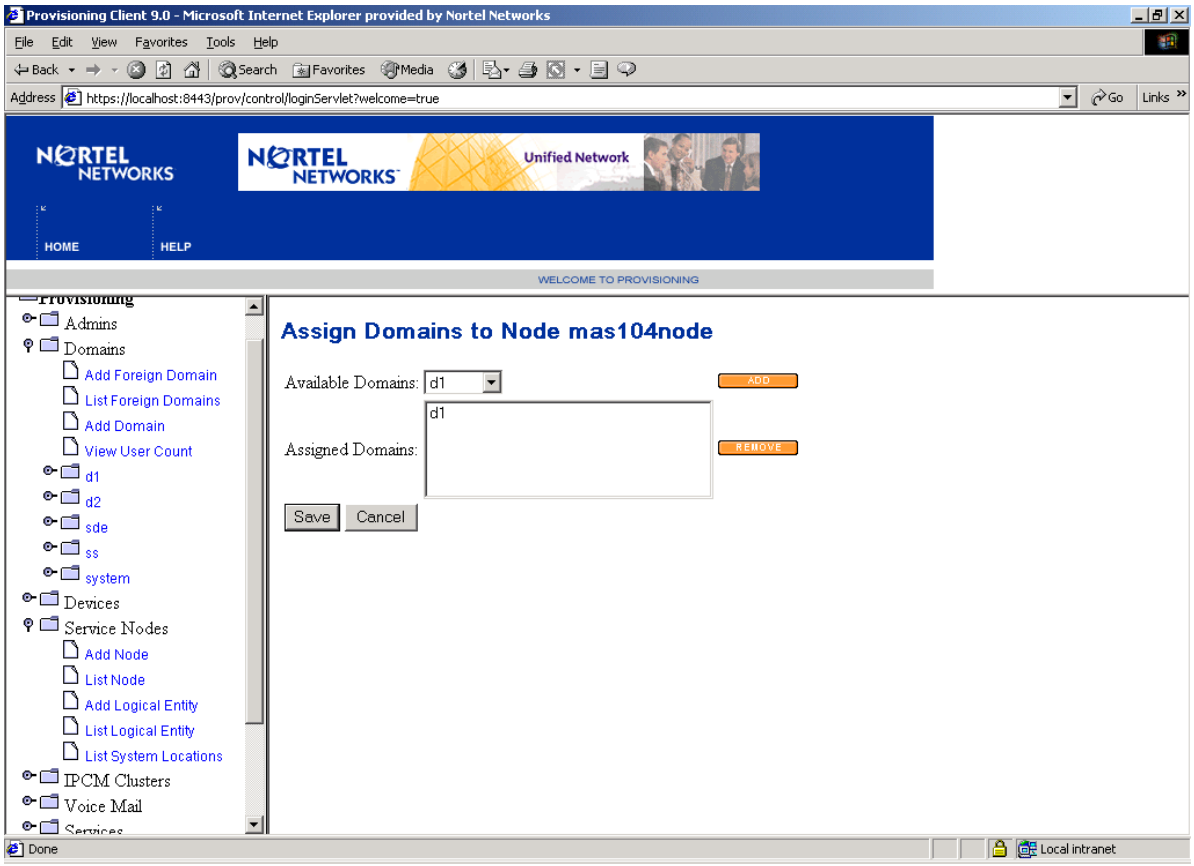


Figure 6: Assign domains to Node

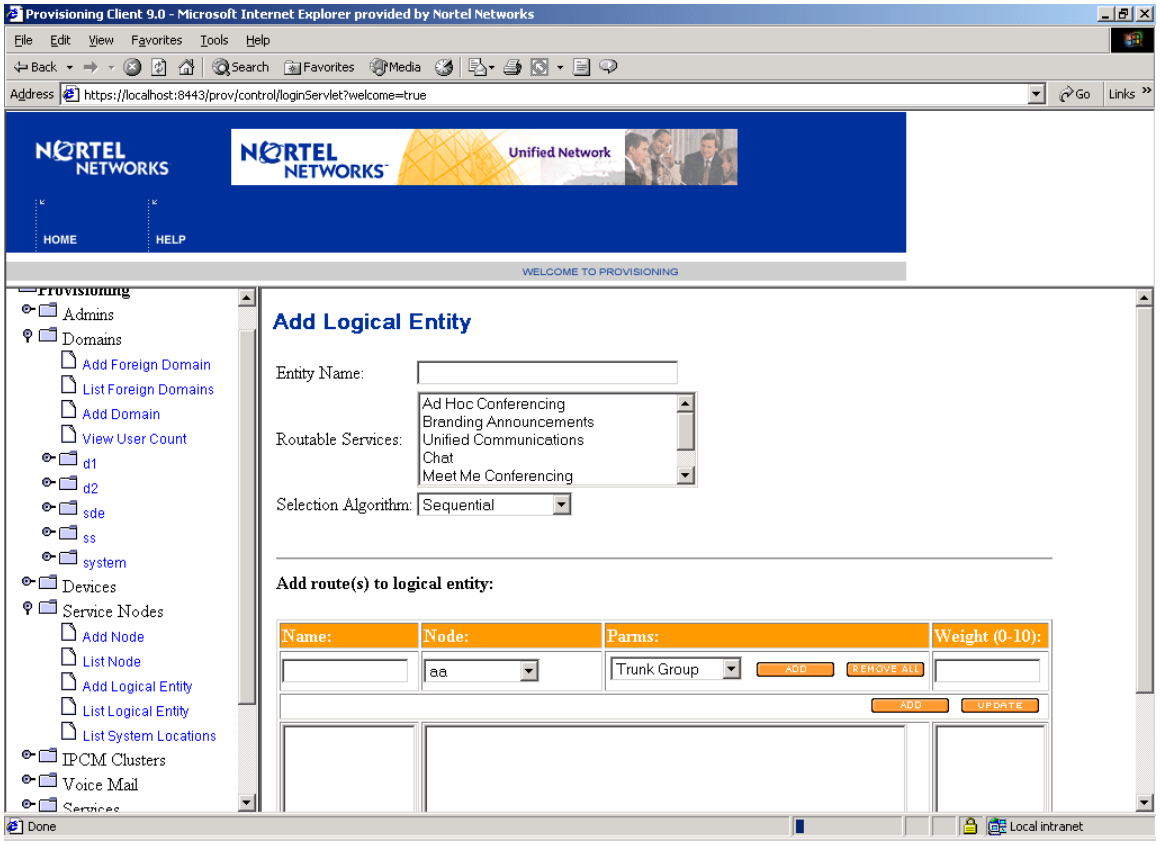
The administrator can also use the nodes to add logical nodes. Logical nodes are comprised of one or more physical nodes and allow for the following:

- **Route parameters**: The admin is given the ability to associate parameters with a given physical node. For example, the admin may have provisioned one physical GW but wants to be able to route to different trunk groups owned by the GW. To do this the admin would create a Logical Node for each trunk group by picking the physical node and then associating a ‘norteltrkgrp’ parameter with it.
- **Pooled Entities**: The admin is also given the ability to define more than one physical node as part of the logical node definition. This provides for the Pooled Entity functionality previously provisioned at the domain level. By placing the PE functionality within the definition of a Logical Node, we have removed the need for the admin to make a distinction between a single node and a PE for the purpose of provisioning in all other areas such as telephony routes, ERLs, etc.

Once the administrator has added the logical entity, the logical entity can be assigned to root domains. Only after the nodes are assigned, the domains can use those to create gateway routes or ERLs or Assign to Routable Services.

A logical entity can contain any of the nodes that are defined in the system. It does not matter if the node is not assigned to a domain. Only the node/ logical entity that are assigned to a domain are available at a particular domain for use. The assignment of nodes to domains gives us the flexibility where a gateway does not need any additional parameters and hence does not need an additional logical entity to be created.

Figure 7: Add Logical Node



The Entity Name is an identifier for the logical entity and is a 30 character max alphanumeric and _ field.

The Routable Services are optional for a Logical entity that is a collection of gateways only.

A new routing algorithm “Sequential” is added which can be used for pooled gateways.

The routes have a name which is a 30 character max alphanumeric and _ field.

The node is the list of nodes provisioned under the dd Node link.

Additional parameters can be added to the route by selecting the elements from the drop down.

A weight of 0 implies that the route is not considered for routing.

Once added, Logical Nodes can be listed as follows:

Figure 8: List Logical Node

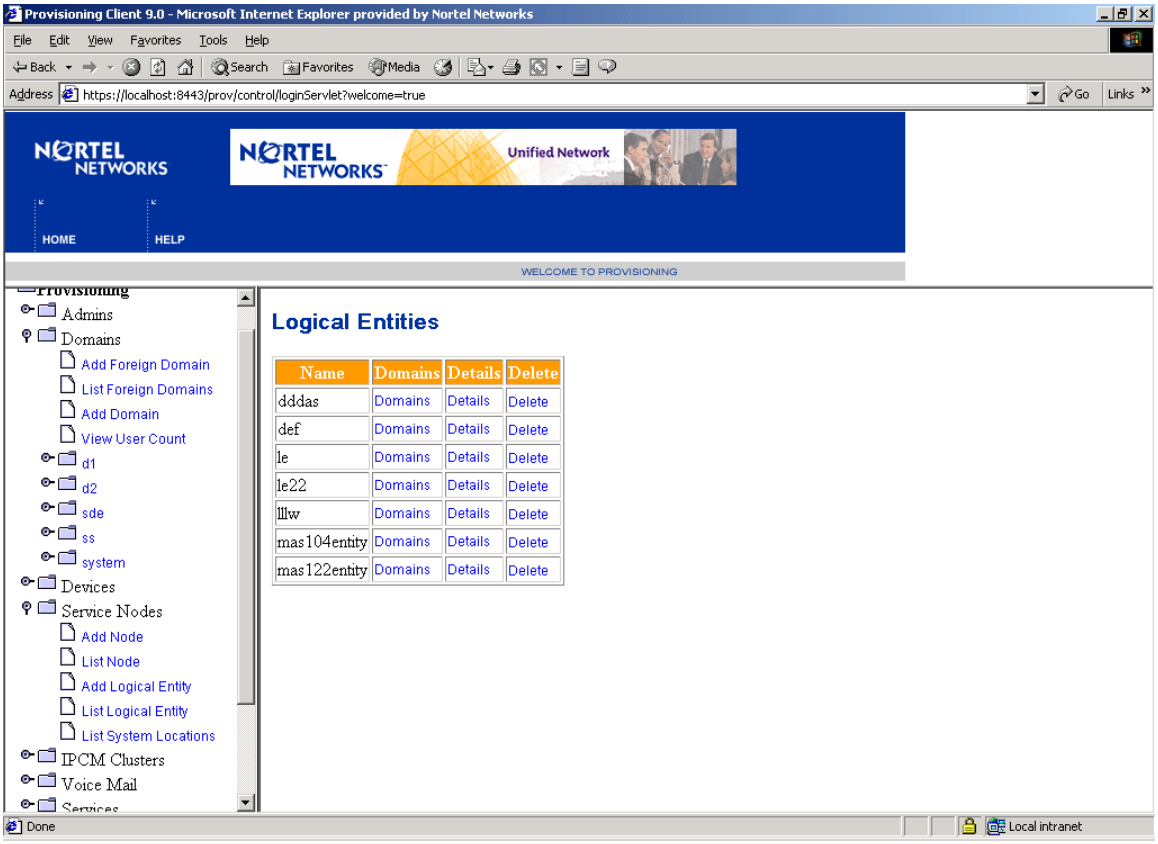


Figure 9: Assign Domains to Logical Entities

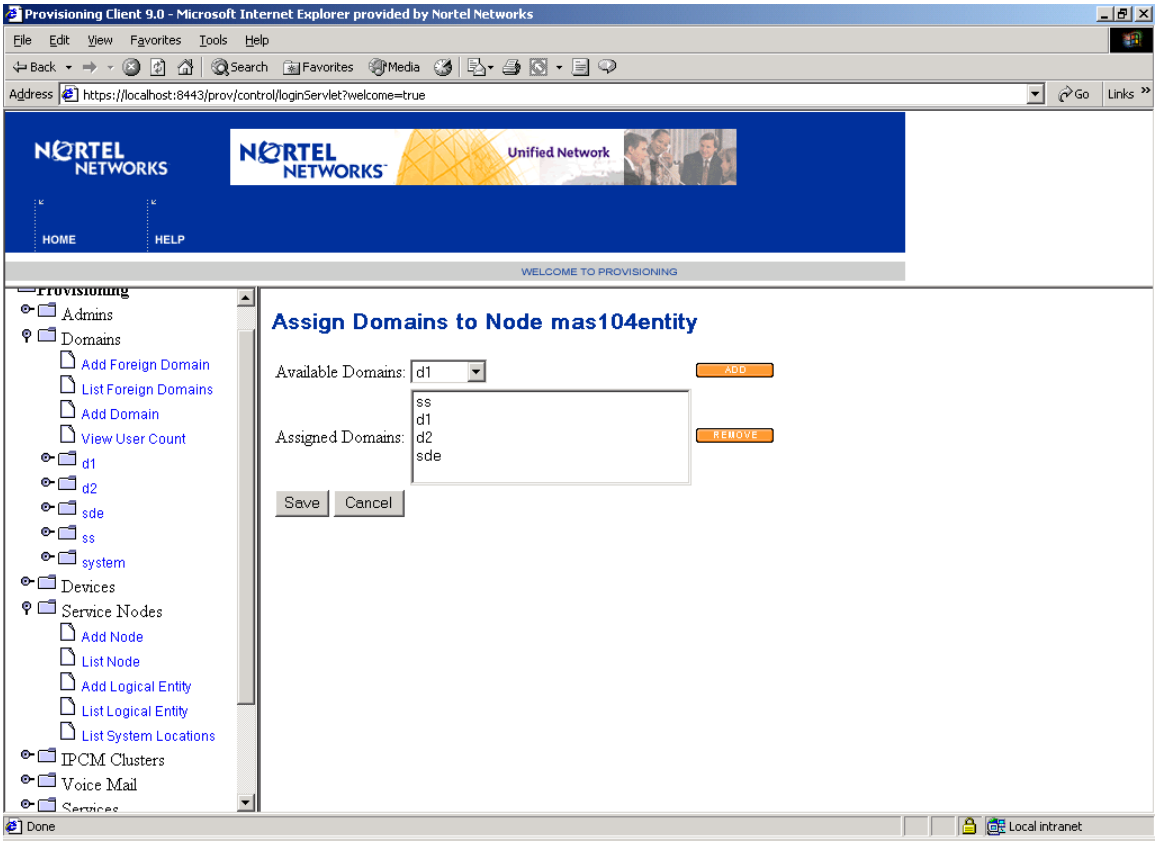

The nodes and logical entities can then be assigned to sub domains at the root domain level by the domain administrator. The sub domain assignement is used only for gateway routes and ERLs that point to the Service Nodes. The Routable Services at the sub domain level still get the entire list that is assigned to the root domain. This is in accordance with how the gateway routes / erls and routable services had access to gateways and pooled entities prior to this feature.

Figure 10: List Nodes for domain

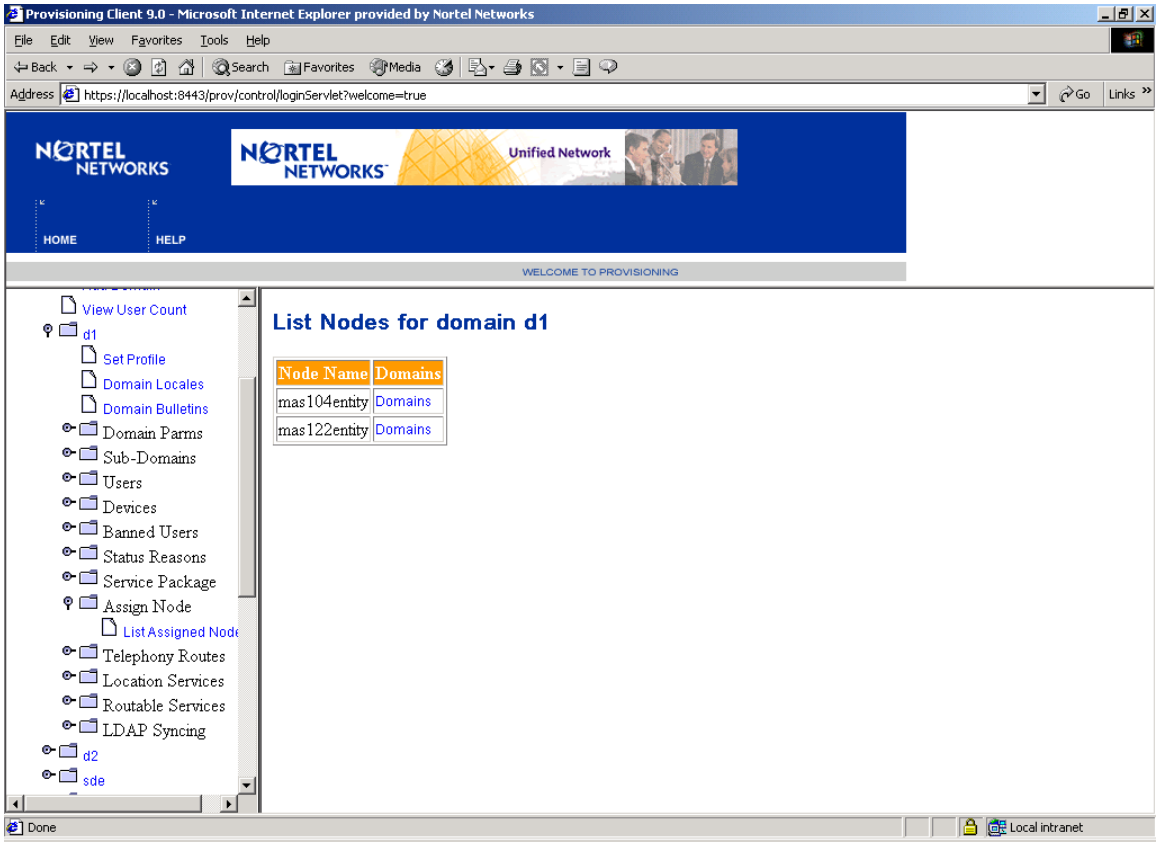

Figure 11: Assign node to sub domains

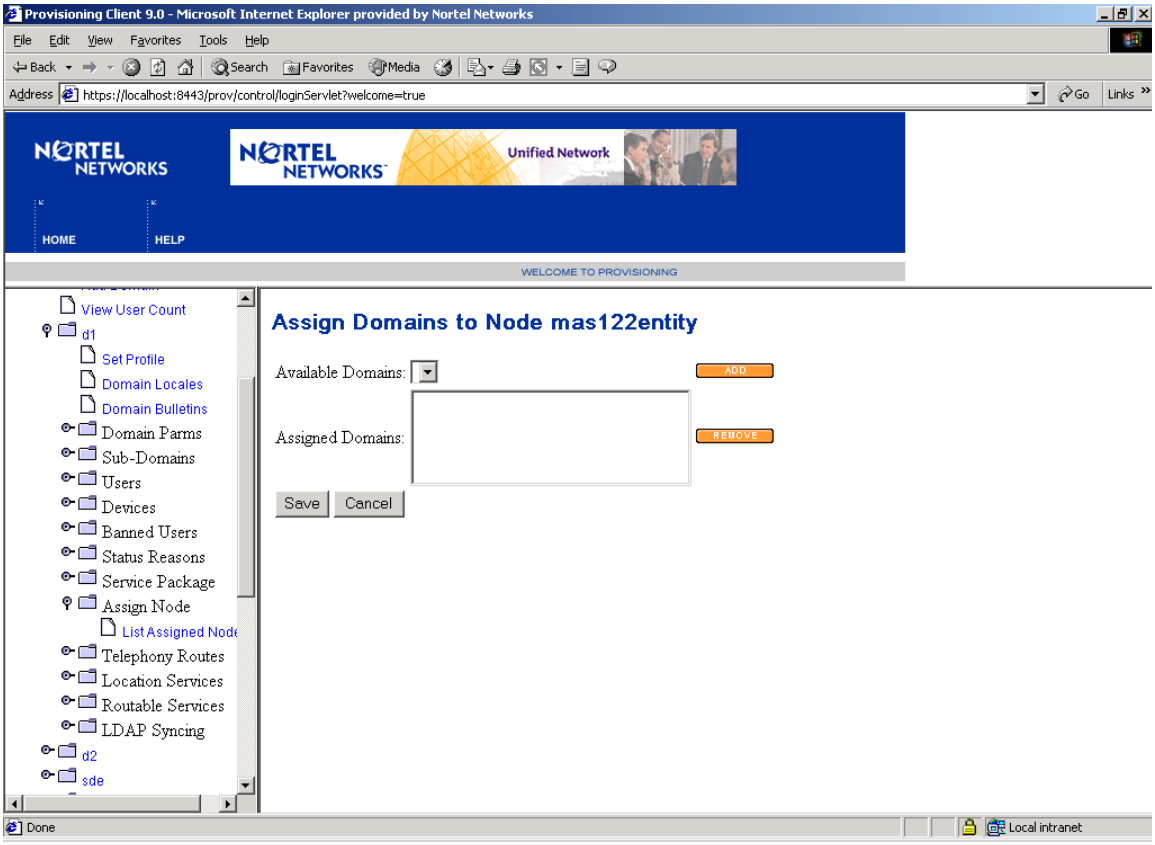


The following methods are being added to support the functionality using OPI.

- public String[] getAllNodeTypeNames() throws ProvisionException;
- public void addNode(Node node) throws ProvisionException;
- public void addNodes(Node[] nodes) throws ProvisionException;
- public void modifyNode(String nodeName, Node node) throws ProvisionException;
- public void removeNode(String nodeName) throws ProvisionException;
- public Node getNode(String nodeName) throws ProvisionException;
- public Node[] getAllNodes() throws ProvisionException;
- public int getNodeCount() throws ProvisionException;
- public void addLogicalEntity(LogicalEntity node) throws ProvisionException;
- public void addLogicalEntitys(LogicalEntity[] nodes) throws ProvisionException;

- public void modifyLogicalEntity(String logicalEntityName, LogicalEntity node) throws ProvisionException;
- public void removeLogicalEntity(String logicalEntityName) throws ProvisionException;
- public LogicalEntity getLogicalEntity(String logicalEntityName) throws ProvisionException;
- public LogicalEntity[] getAllLogicalEntitys() throws ProvisionException;
- public int getLogicalEntityCount() throws ProvisionException;
- public void assignDomainsToNode(String nodeName, String[] domains) throws ProvisionException;
- public String[] getNodeDomains(String nodeName) throws ProvisionException;
- public String[] getNodeSubDomains(String domainName, String nodeName) throws ProvisionException;
- public String[] getAllNodeNamesForDomain(String domainName) throws ProvisionException;
- public void assignNodeToSubDomains(String parentDomainName, String nodeName, String[] subdomains) throws ProvisionException;
- public String[] getDomainNodes(String domainName) throws ProvisionException;
- public String[] getAllRoutableServices() throws ProvisionException;
- public String[] getAllRoutableServiceGroups() throws ProvisionException;
- public String[] getAllNodesByRoutableService(String domain, String service) throws ProvisionException;
- public String[] getAllNodesByRoutableServiceGroup(String domain, String serviceGroup) throws ProvisionException;
- public String getAssignedNodeByDomainByServiceGroup(String domain, String serviceGroup) throws ProvisionException;
- public String getAssignedNodeByLocationByServiceGroup(String domain, String location, String serviceGroup) throws ProvisionException;
- public void assignNodeToDomain(String domain, String nodeName, String serviceGroup) throws ProvisionException;
- public void assignNodeToLocation(String domain, String location, String nodeName, String serviceGroup) throws ProvisionException;
- public void assignNodeToLocations(String domain, String[] location, String nodeName, String serviceGroup) throws ProvisionException;

- public String[] getAllLocationsForNodeByServiceGroup(String domain, String nodeName, String serviceGroup) throws ProvisionException;
- public String[] getAllAvailableLocationsByServiceGroup(String domain, String serviceGroup) throws ProvisionException;

102.5.1.1 Steps to provision Service Nodes

To add a gateway:

Step 1:

To add an Audio Codes Gateway: Add an AudioCodeServer on SM.

To add an H323 GK:Add an H323 GK on SM.

To add any other kind of Gateway: Add an Info Element of type Gateway on SM

a. Add Address on SM
b. Add an External Node on SM
c. Add an Info Element of type Gateway. Add the port if any specific port.

Step 2:

Add a Node on Prov

Service Nodes -> Add Node

Choose the name of the Audio Code Server or the H323GK or InFo Element that you added.

Assign the node to the domain that you want to use it for. The link is on the List Nodes page against the Node name.

If you do not need any parms etc, you are good to go.

Add a Logical Entity on Prov

Service Nodes -> Add Logical Entity

Give a name. Routing Algorithm Sequential.

Add routes: This is equivalent to the Gateway routes in the old world.

Give a name to the route.

Select the node you added as the destination.

From the drop down, select trunggroup and add the tg info.

Select facility domain if you want to provide one.

nn.com;maddr=IP:port;norteltrkgrp=xyz

In this nn.com is your facility domain, and xyz is the trunk group parameter.

To add a MAS:

Step 1:

To add a MAS: Add a MAS on SM.

To add any other kind of Pooled Media Resource: Add an Info Element of type Pooled Media Resource on SM

a) Add Address on SM

b) Add an External Node on SM

c) Add an Info Element of type Pooled Media Resource. Add the port if any specific port.

Step 2:

Add a Node on Prov

Service Nodes -> Add Node

Choose the name of the MAS or InFo Element that you added.

Assign the node to the domain that you want to use it for. The link is on the List Nodes page against the Node name.

Add a Logical Entity on Prov

Service Nodes -> Add Logical Entity

Give a name. Routing Algorithm Weighted Average.

Add routes: This is equivalent to the Pooled Entity Routes in the old world.

Give a name to the route.

Select the node you added as the destination.

Assign Logical Entities to Domains and then the rest is as it used to be.

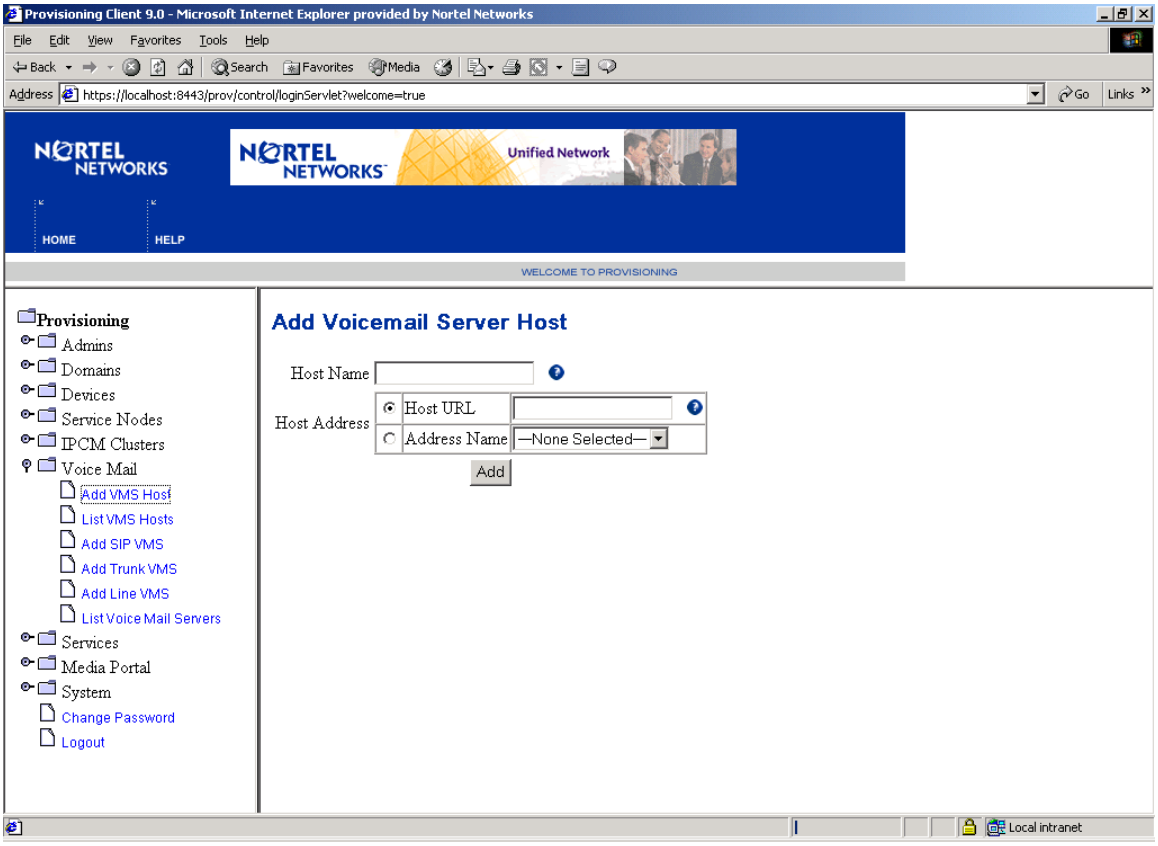
102.5.2 Voicemail Server Provisioning

102.5.2.1 Voicemail Server Host

A new menu is added to provision the host for Voicemail Servers. This is needed because the existing voicemail servers may have a URI provisioned which translates to a voicemail server instead of actual server info. There is no way for the upgrade to figure out the node.

Hence the existing URI can be used or a node can be provisioned to add a voicemail server host.

Figure 12: Add Voicemail Server Host



The host name is an identifier for the node and has a maximum length of 30 characters. Only alpha numeric and _ chars are allowed.

The Host URL / Address Name fields are mutually exclusive and only one can be enetered.

The Host URL field is available so that the existing VM server configuration still works. No data available in this field is validated and the data is not reipable.

If the customer chooses to add an IP here, and use it instead of the right way of selecting a node, then this data would not be re-ipable.

The Address Name is the list of nodes/ logical entities provisioned on the system.

The List VM Hosts page displays the list of hosts.

Figure 13: List VM Server Hosts

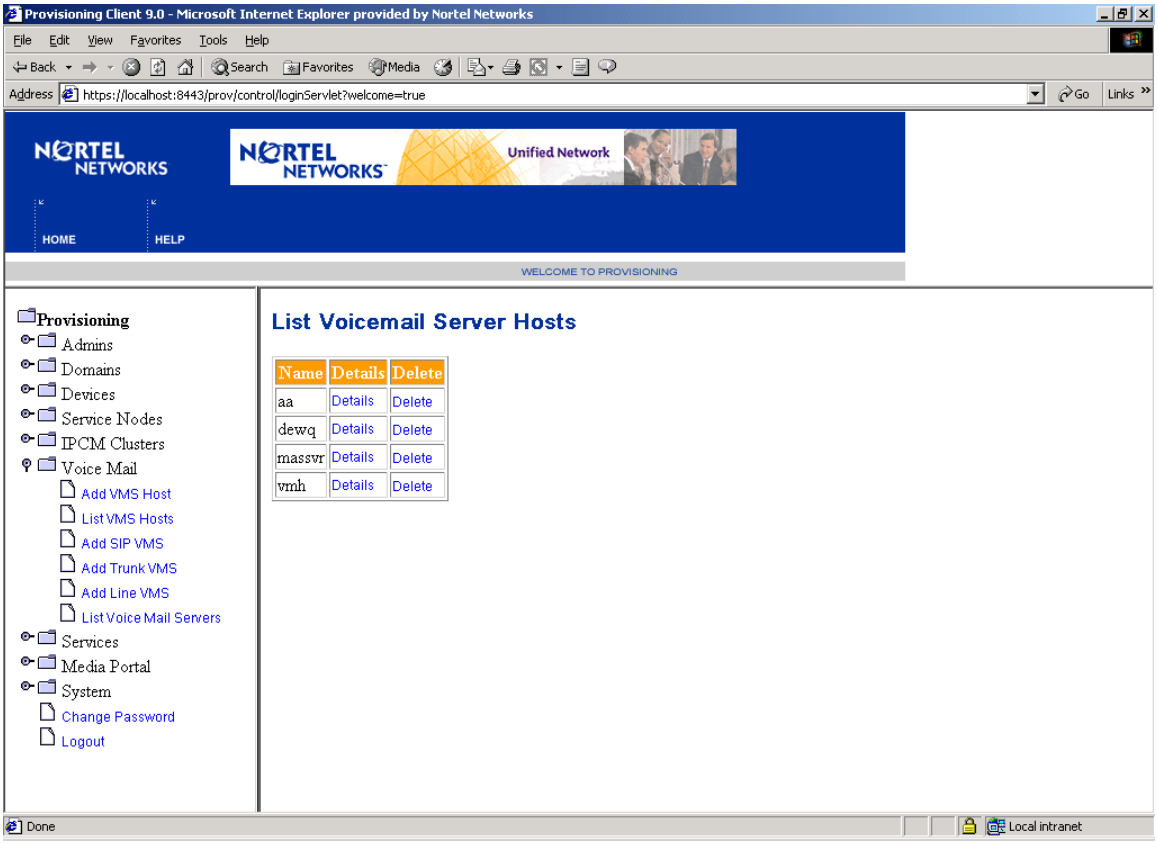


Figure 14: SIP Voicemail Server

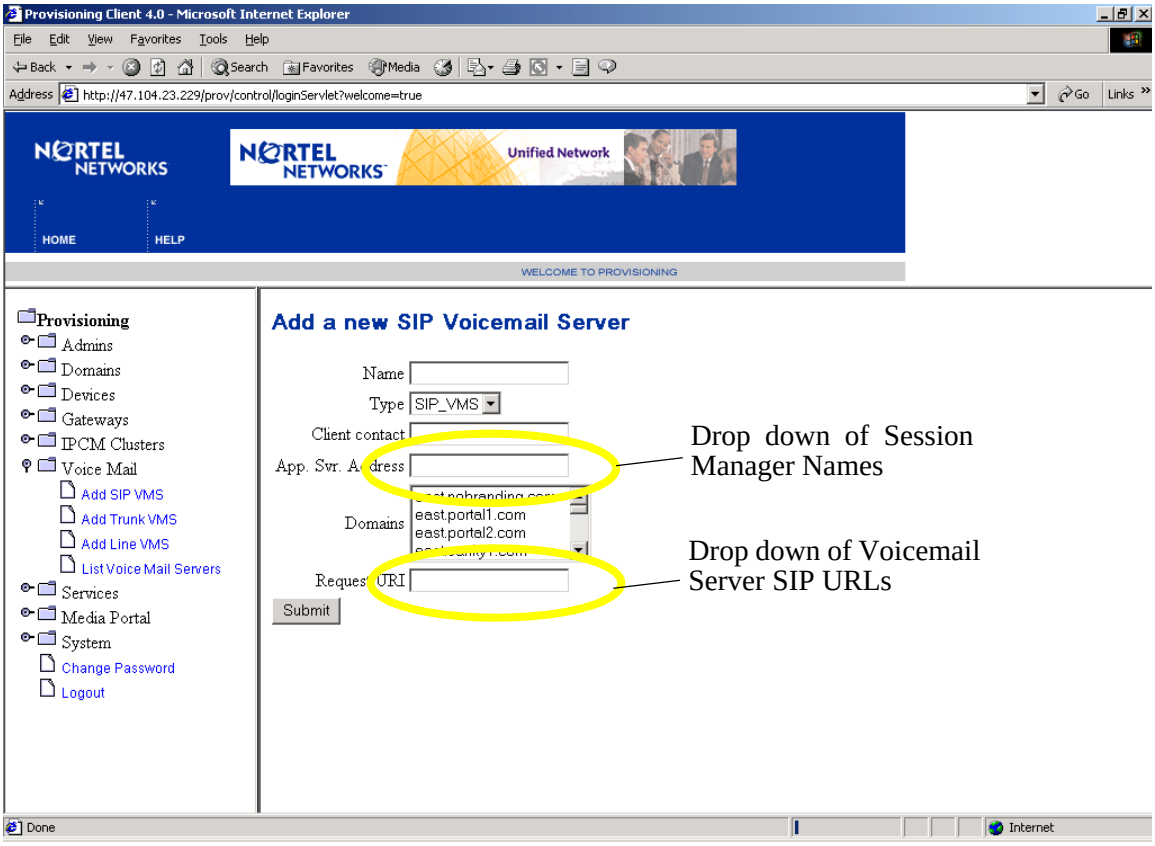

Figure 15: Trunk Voicemail Server

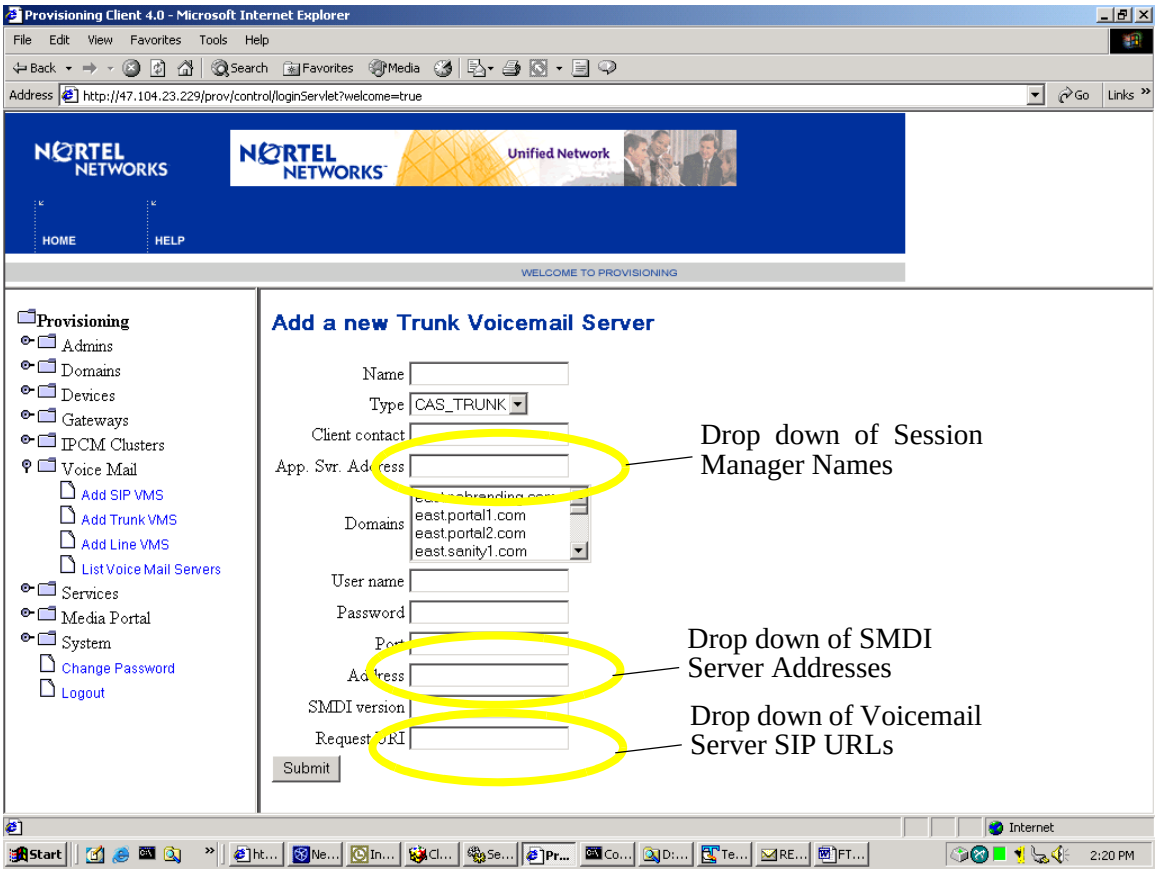

Figure 16: Line Voicemail Server

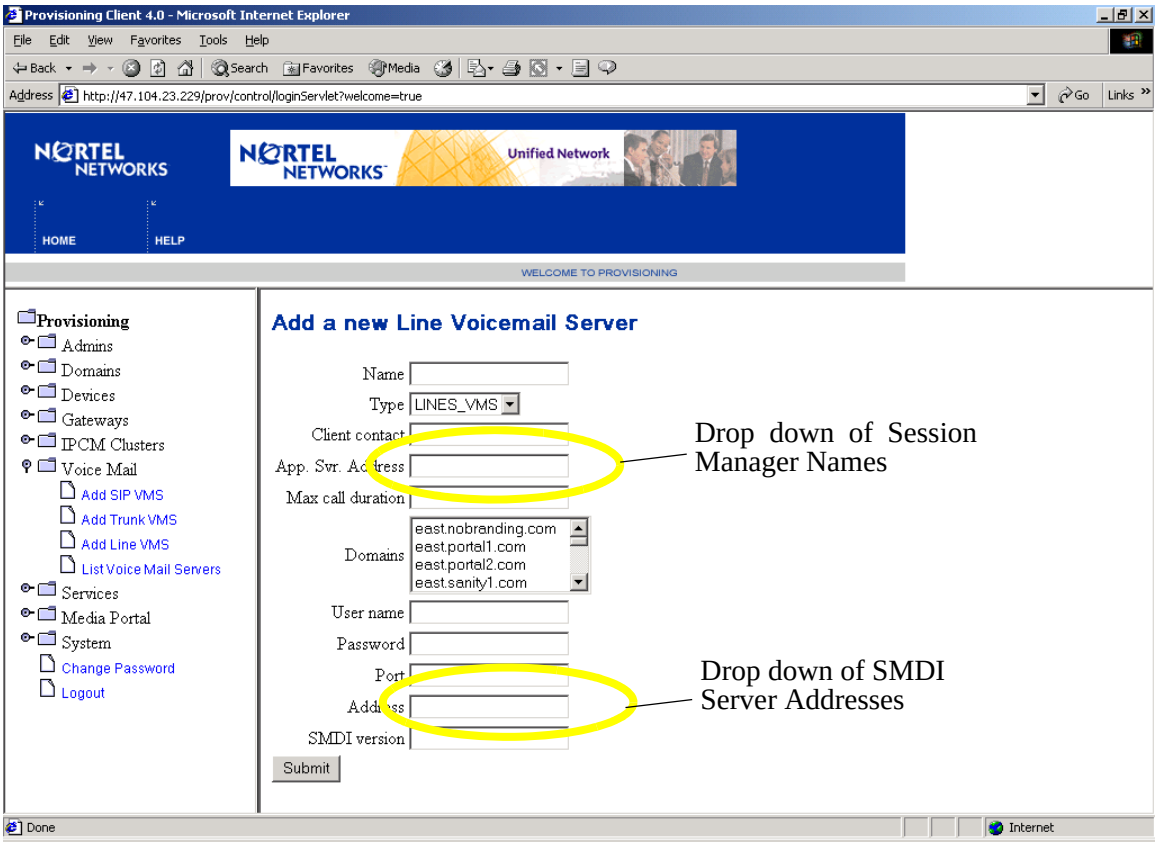

Figure 17: Line Provisioning

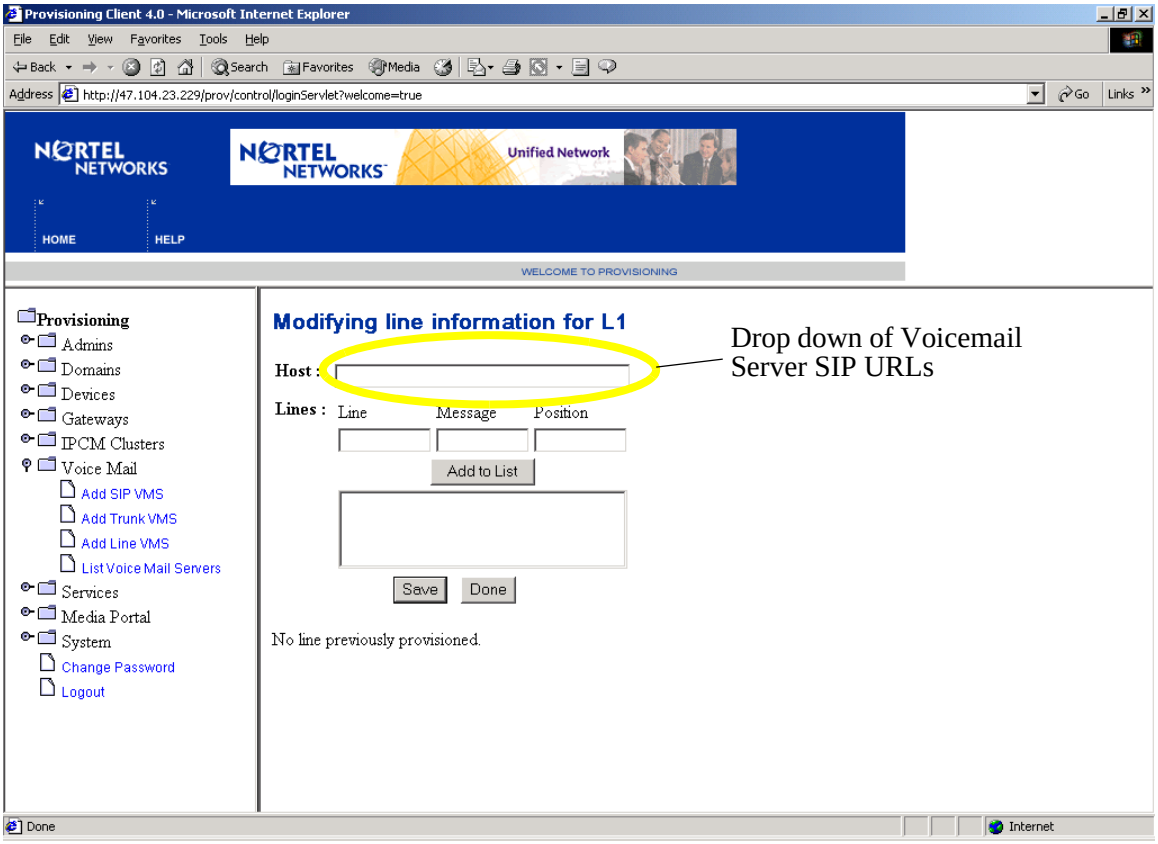


102.5.2.2 App Server IP Address

SIP, LINE and TRUNK Voicemail Server Provisioning require the operator to enter the Application Server IP address.

This will be changed on the Provisioning Client to let the operator select a Session Manager from a list containing logical names for all the Session Managers configured on the system.

The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile. The OPI client would now have to send the Session Manager name instead of the IP Address in the Voicemail data object. The field is highlighted below in the example for SIPVoicemailServer. The same is true for Line and Trunk Voicemail Servers also.

Usage: addSIPVoicemailServer using ([The name of the voicemail server,the type of voicemail server,The client contact for the voicemail, right now the string voicemail is used,**The address of the appserver which will be used by**

the voicemail server in an n+m scenario,The maximum amount of time that the call will be tried before rolling off to voicemail,[The domains that the voicemail server would serve, .. ,The domains that the voicemail server would serve],[The host of the SIP voicemail server, .. ,The host of the SIP voicemail server]])

The following OPI methods would now contain the Session Manager name as opposed to the IP Address.

- public void addSIPVoicemailServer(SIPVoicemailServer sipVms) throws ProvisionException;
- public void modifySIPVoicemailServer(String serverName, SIPVoicemailServer sipVms) throws ProvisionException;
- public SIPVoicemailServer[] getAllSIPVoicemailServers() throws ProvisionException;
- public SIPVoicemailServer[] getAllSIPVoicemailServersByDomain(String domainName) throws ProvisionException;
- public void addTrunkVoicemailServer(TrunkVoicemailServer trunkVms) throws ProvisionException;
- public void modifyTrunkVoicemailServer(String serverName, TrunkVoicemailServer trunkVms) throws ProvisionException;
- public TrunkVoicemailServer[] getAllTrunkVoicemailServers(String trunkType) throws ProvisionException;
- public TrunkVoicemailServer[] getTrunkVoicemailServerByDomain(String domainName, String trunkServerName) throws ProvisionException;
- public void addLineVoicemailServer(LineVoicemailServer trunkVms) throws ProvisionException;
- public void modifyLineVoicemailServer(String serverName, LineVoicemailServer lineVms) throws ProvisionException;
- public LineVoicemailServer[] getAllLineVoicemailServers() throws ProvisionException;
- public LineVoicemailServer[] getLineVoicemailServerByDomain(String domain) throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServers()throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServersByDomain(String domainName)throws ProvisionException;

Changes will be made on the Session Manager to use the name to resolve the IP address.

102.5.2.3 SMDI Server IP Address and Port

LINE and TRUNK Voicemail Server Provisioning require the operator to enter the SMDI Server IP address and port.

This will be changed to let the operator select a SMDI Server from a list containing logical names for all the iTouch Terminal Server addresses configured on the system.

The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile. The OPI client would now have to send the SMDI Server name instead of the IP Address in the VmTerminalServer data object. The Port field is no longer used and is deprecated in this release.

The following OPI methods would now contain the SMDI Server name as opposed to the IP Address.

- public void addTrunkVoicemailServer(TrunkVoicemailServer trunkVms) throws ProvisionException;
- public void modifyTrunkVoicemailServer(String serverName, TrunkVoicemailServer trunkVms) throws ProvisionException;
- public TrunkVoicemailServer[] getAllTrunkVoicemailServers(String trunkType) throws ProvisionException;
- public TrunkVoicemailServer[] getTrunkVoicemailServerByDomain(String domainName, String trunkServerName) throws ProvisionException;
- public void addLineVoicemailServer(LineVoicemailServer trunkVms) throws ProvisionException;
- public void modifyLineVoicemailServer(String serverName, LineVoicemailServer lineVms) throws ProvisionException;
- public LineVoicemailServer[] getAllLineVoicemailServers() throws ProvisionException;
- public LineVoicemailServer[] getLineVoicemailServerByDomain(String domain) throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServers()throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServersByDomain(String domainName)throws ProvisionException;

Changes will be made on the Session Manager to use the name to resolve the IP address.

102.5.2.4 Request URI and Host

SIP, LINE and TRUNK Voicemail Server Provisioning require the operator to enter the host in the Request URI and Host fields.

This will be changed to let the operator select a pre-provisioned Voicemail Server Host.

The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile. The OPI client would now have to send the VM Host name instead of the entire SIPURI in the host field.

The following OPI methods would now contain the VM Host name as opposed to the entire SIP URI.

- public void addSIPVoicemailServer(SIPVoicemailServer sipVms) throws ProvisionException;
- public void modifySIPVoicemailServer(String serverName, SIPVoicemailServer sipVms) throws ProvisionException;
- public SIPVoicemailServer[] getAllSIPVoicemailServers() throws ProvisionException;
- public SIPVoicemailServer[] getAllSIPVoicemailServersByDomain(String domainName) throws ProvisionException;
- public void addTrunkVoicemailServer(TrunkVoicemailServer trunkVms) throws ProvisionException;
- public void modifyTrunkVoicemailServer(String serverName, TrunkVoicemailServer trunkVms) throws ProvisionException;
- public TrunkVoicemailServer[] getAllTrunkVoicemailServers(String trunkType) throws ProvisionException;
- public TrunkVoicemailServer[] getTrunkVoicemailServerByDomain(String domainName, String trunkServerName) throws ProvisionException;
- public void addLineVoicemailServer(LineVoicemailServer trunkVms) throws ProvisionException;
- public void modifyLineVoicemailServer(String serverName, LineVoicemailServer lineVms) throws ProvisionException;
- public LineVoicemailServer[] getAllLineVoicemailServers() throws ProvisionException;

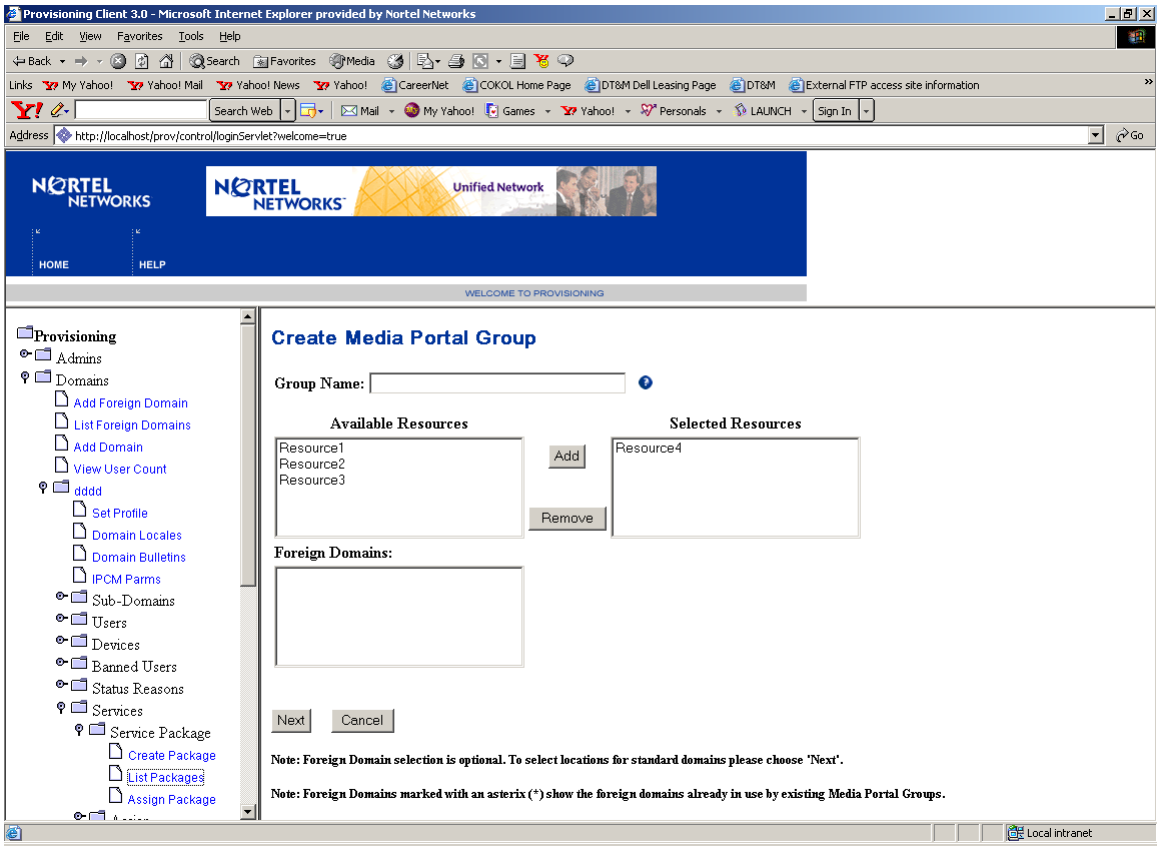
- public LineVoicemailServer[] getLineVoicemailServerByDomain(String domain) throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServers()throws ProvisionException;
- public VoicemailServer[] getAllVoicemailServersByDomain(String domainName)throws ProvisionException;

The domains as assigned to voicemail servers the same way as they were done before. If a Service Node is selected for creating the voicemail server host/ the domains that it is assigned to has no impact on the list of domains that the VM server can be assigned to.

102.5.3 Media Portal Group

The Media Portal Group provisioning uses direct IP addresses for a list of available and assigned resources. This will change to display the media portal logical names in the two lists on the Provisioning Client.

Figure 18: Media Portal Groups provisioning



The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile. The OPI client would now have to send the RTP Portal names instead of the IP Address in the MediaPortalGroup data object.

The following OPI methods would now contain the MediaPortal name as opposed to the IP Address.

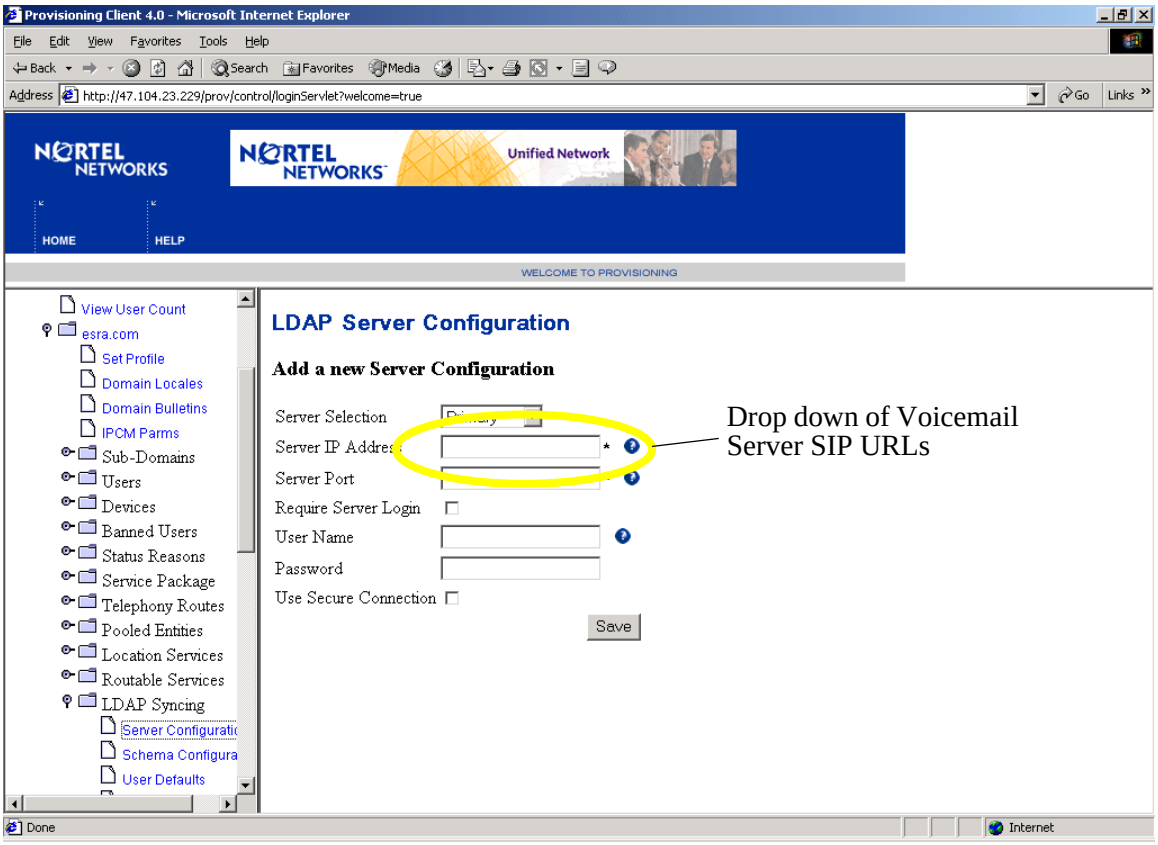
- public void addMediaPortalGroup (MediaPortalGroup mpgroup) throws ProvisionException;
- public void addMediaPortalGroups (MediaPortalGroup[] mpgroups) throws ProvisionException;
- public void modifyMediaPortalGroup(String groupName,MediaPortalGroup mpgroup) throws ProvisionException;
- public MediaPortalGroup getMediaPortalGroupByName(String groupName)throws ProvisionException;
- public MediaPortalGroup[] getAllMediaPortalGroups()throws ProvisionException;
- public String[] getAllMediaPortalResourceIPs() throws ProvisionException;

Change will be required on the Session Manager to handle this change.

102.5.4 LDAP Server Configuration

The LDAP Server provisioning require the operator to enter the SMDI Server IP address and port. This will change to display the LDAP Server logical names on the Provisioning Client.

Figure 19: LDAP Server Provisioning



The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile. The OPI client would now have to send the LDAP Server names instead of the IP Address in the LDAPInfo data object for the Primary and Secondary servers.

The following OPI methods would now contain the LDAP Server name as opposed to the IP Address.

- public void addLdapInfo(String domainName, LDAPInfo ldapInfo)throws ProvisionException;
- public LDAPInfo[] getLdapInfo(String domainName) throws ProvisionException;

102.5.5 Gateway Provisioning

This whole menu item has been removed from the system in favor of the new Service Nodes provisioning (see above). The Gateway Provisioning Right is removed.

OPI methods removed:

- public void addGateway(Gateway gateway) throws ProvisionException;
- public void addGateways(Gateway[] gateways) throws ProvisionException;
- public void modifyGateway(String gatewayHost, String gatewayType, Gateway gateway) throws ProvisionException;
- public void removeGateway(String gatewayHost, String gatewayType) throws ProvisionException;
- public void addGatewayRoute(String domainName,GatewayRoute gatewayRoute) throws ProvisionException;
- public void addGatewayRoutes(String domainName,GatewayRoute[] gatewayRoutes) throws ProvisionException;
- public void modifyGatewayRoute(String domainName,String routeName, String updatedDomainName,
- GatewayRoute gatewayRoute) throws ProvisionException;
- public void removeGatewayRoute(String domainName,String routeName) throws ProvisionException;
- public void addTrunkGroup(String domainName,TrunkGroup trunkGroup) throws ProvisionException;
- public void addTrunkGroups(String domainName,TrunkGroup[] trunkGroups) throws ProvisionException;
- public void modifyTrunkGroup(String domainName,TrunkGroup trunkGroup, TrunkGroup updatedTrunkGroup)
- throws ProvisionException;
- public void removeTrunkGroup(String domainName,TrunkGroup trunkGroup)throws ProvisionException;
- public TrunkGroup[] getTrunkGroups()throws ProvisionException;
- public Gateway[] getGateways()throws ProvisionException;
- public Gateway[] getGatewayByType(String gatewayType)throws ProvisionException;
- public GatewayRoute[] getGatewayRoutes()throws ProvisionException;
- public GatewayRoute[] getGatewayRoutesByDomain(String domainName)throws ProvisionException;
- public GatewayRoute[] getGatewayRoutesByName(String routeName) throws ProvisionException;
- public String[] getAllGatewayTypeNames() throws ProvisionException;

102.5.6 Pooled Entity Routes Provisioning

Pooled Entity provisioning has been removed altogether and has been replaced by Service Nodes at the system level (see above). No functionality has been lost by this transition.

Routable Services use the Pooled Entity Provisioning Rights. This was also used for Pooled Entity Provisioning. This right will now only be used by Routable Services.

OPI methods Removed:

- public void addPooledEntity(String domainName, PooledEntity pooledEntity) throws ProvisionException;
- public PooledEntity[] getAllPooledEntities(String domainName) throws ProvisionException;
- public PooledEntity getPooledEntity(String domainName, String pooledEntityName) throws ProvisionException;
- public void modifyPooledEntity(String domainName, String pooledEntityName, PooledEntity pooledEntity) throws ProvisionException;
- public void deletePooledEntity(String domainName, String pooledEntityName) throws ProvisionException;
- public String[] getAllPooledEntityServices() throws ProvisionException;
- public String[] getAllPooledEntitiesByService(String domain, String service) throws ProvisionException;
- public String[] getAllPooledEntitiesByServiceGroup(String domain, String serviceGroup) throws ProvisionException;
- public String getAssignedPoolByDomain(String domain, String serviceGroup) throws ProvisionException;
- public String getAssignedPoolByLocation(String domain, String location, String serviceGroup) throws ProvisionException;
- public void assignPoolToDomain(String domain, String poolName, String serviceGroup) throws ProvisionException;
- public void assignPoolToLocation(String domain, String location, String poolName, String serviceGroup) throws ProvisionException;
- public void assignPoolToLocations(String domain, String[] location, String poolName, String serviceGroup) throws ProvisionException;
- public String[] getAllLocationsForPool(String domain, String pool, String serviceGroup) throws ProvisionException;
- public String[] getAllAvailableLocations(String domain, String serviceGroup) throws ProvisionException;

- public String[] getAllPooledEntityServiceGroups() throws ProvisionException;

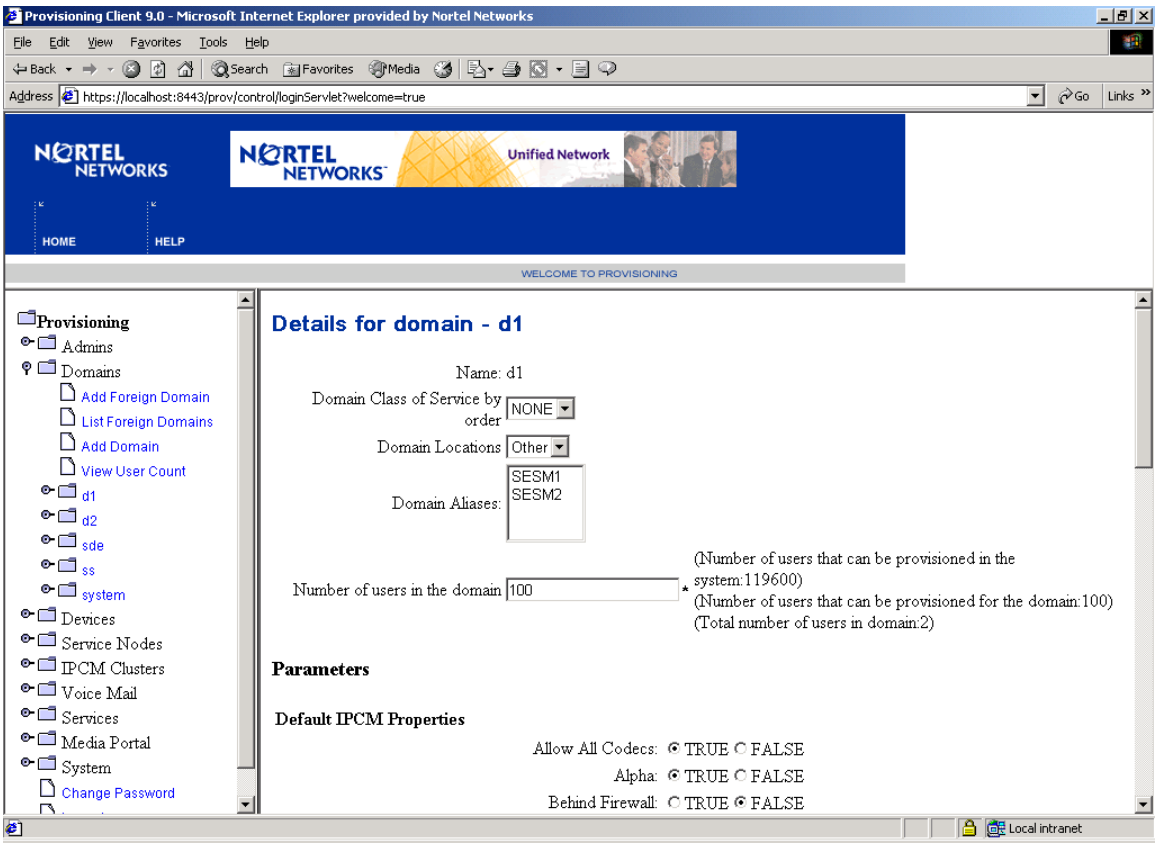
102.5.7 Domain Alias

The domain alias is changed to be the names of addresses that it represents.

The Domain Alias can either be a Session manager or an Info Element of type General.

The Add Domain page now lists these names instead of letting the customer enter free form IP addresses.

Figure 20: Add Domain



The following OPI methods now have the short name of the SM elements instead of IP addresses in the alias field.

- public void addRootDomain(Domain domain) throws ProvisionException;

- public void addSubDomain(String parentDomainName, Domain domain) throws ProvisionException;
- public void modifyDomain(String domainName,Domain domain) throws ProvisionException;
- public Domain[] getAllDomains() throws ProvisionException;
- public Domain[] getChildrenDomains(String parentName) throws ProvisionException;
- public Domain getParentDomain(String subDomainName) throws ProvisionException;
- public Domain getRootDomain(String domainName) throws ProvisionException;
- public Domain[] getDomains(int start, int stop) throws ProvisionException;

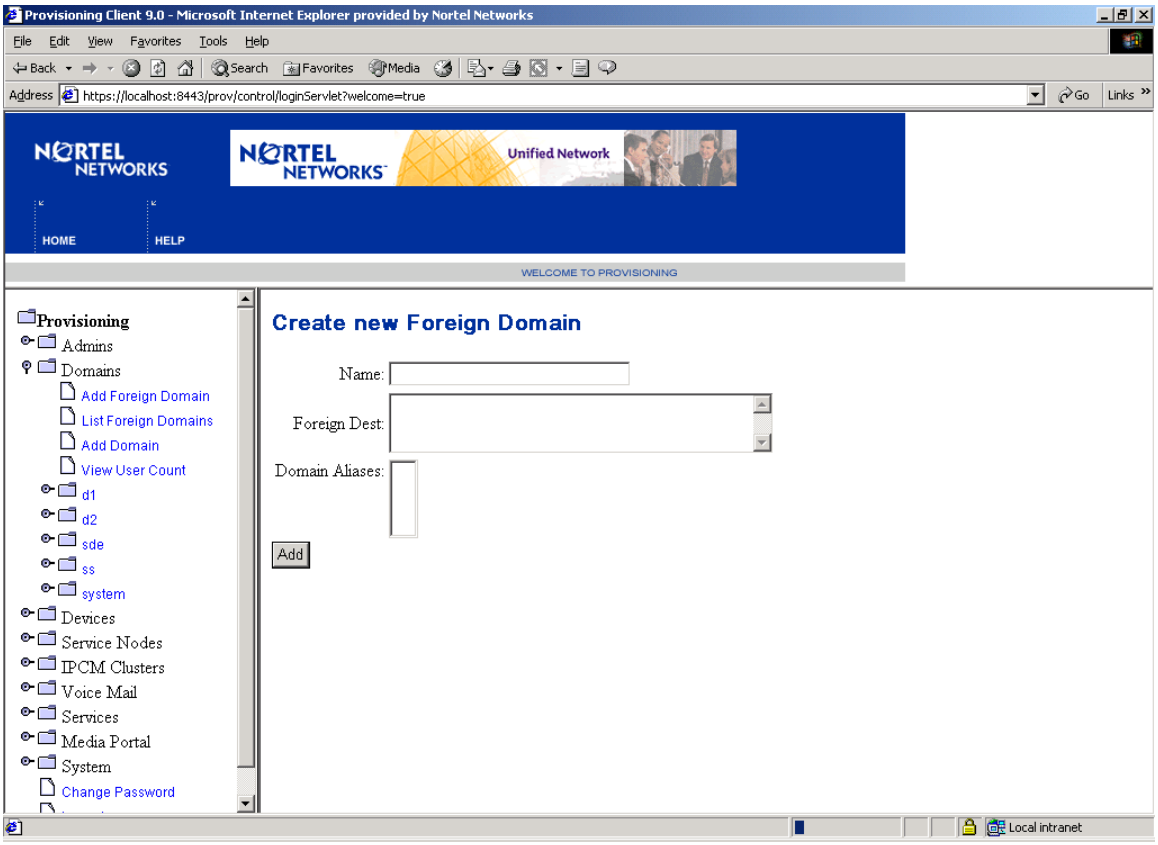
102.5.8 Foreign Domain Alias

The foreign domain alias is changed to be the names of addresses that it represents.

The Domain Alias can be an Info Element of type General.

The Add Foreign Domain page now lists these names instead of letting the customer enter free form IP addresses.

Figure 21: Add Foreign Domain



The following OPI methods now have the short name of the SM elements instead of IP addresses in the alias field.

- public void addForeignDomain(ForeignDomain forDomain) throws ProvisionException;
- public void modifyForeignDomain(String name,ForeignDomain forDomain) throws ProvisionException;
- public ForeignDomain getForeignDomain(String forDomains) throws ProvisionException;

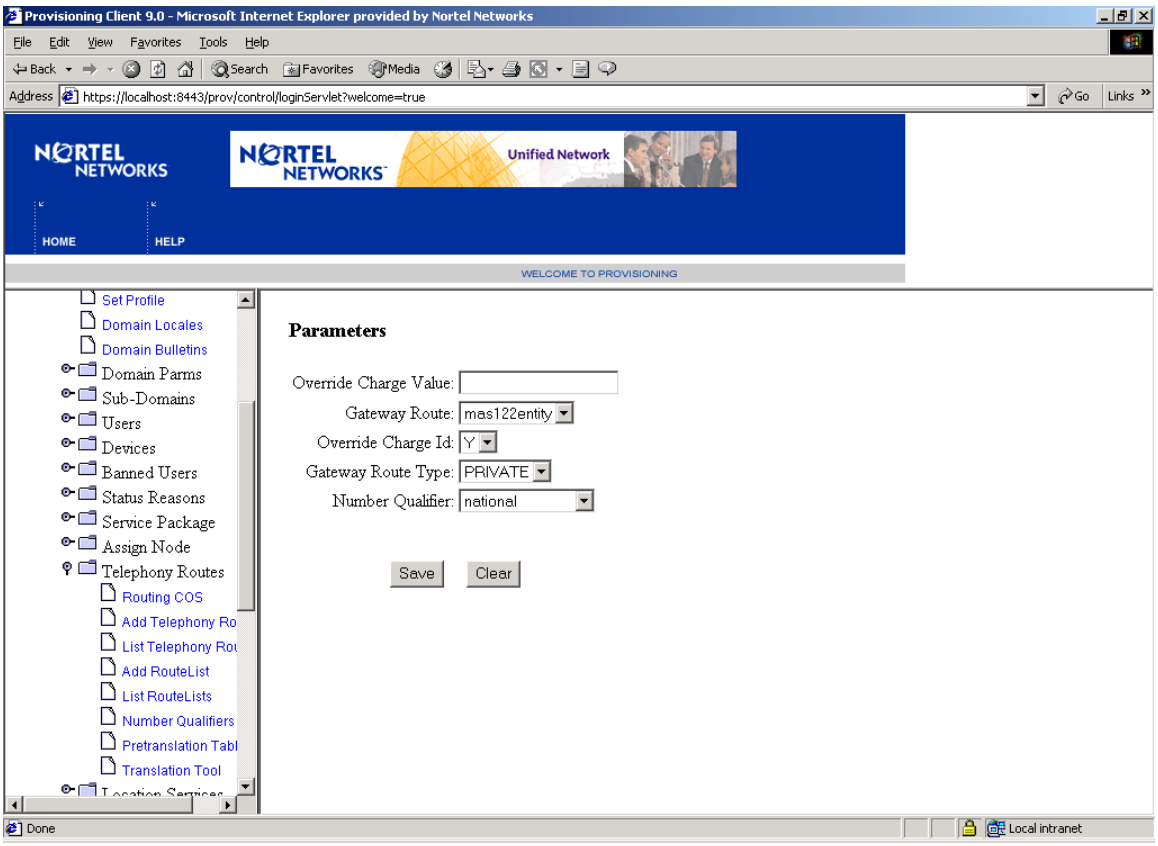
The foreign Dest field is left as is. Since these are addresses of external systems, there is no need for ReIP support on these.

102.5.9 Telephony Routes

102.5.9.1 Gateway Telephony Routes

The Gateway Telephony routes will now select a node/ logical entity assigned to the domain/ sub domain instead of the gateway routes as in previous releases.

Figure 22: Gateway Telephony Routes



The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile.

The following OPI methods would now contain the node/ logical entity names instead of the gateway route names.

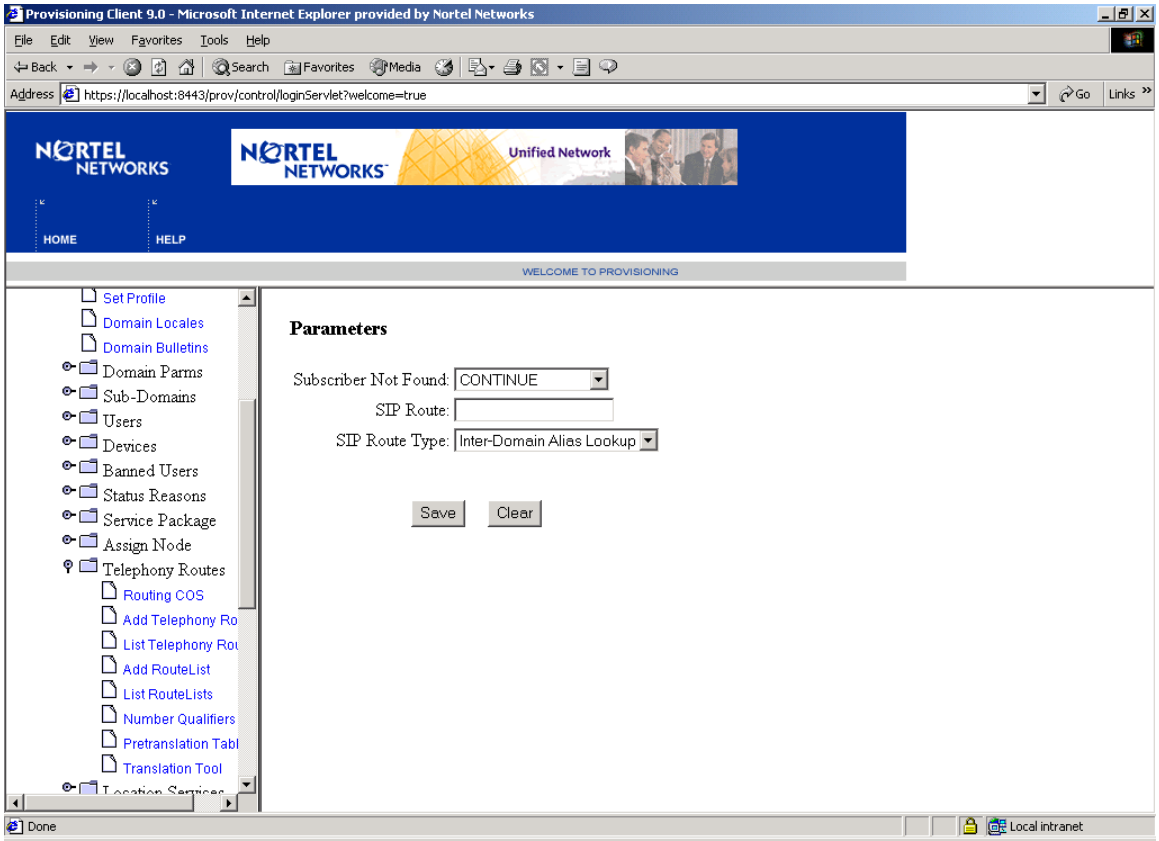
- public void addTelephonyRoute (String domainName, TelephonyRoute teleRoute) throws ProvisionException;
- public void addTelephonyRoutes (String domainName, TelephonyRoute[] teleRoutes) throws ProvisionException;
- public TelephonyRoute[] getTelephonyRoutesByDomain (String domainName) throws ProvisionException;

- public TelephonyRoute[] getTelephonyRoute (String domainName, String routeName) throws ProvisionException;
- public void modifyTelephonyRoute (String domainName,String routeName,TelephonyRoute teleRoute) throws ProvisionException;

102.5.9.2 SIP Telephony Routes

Telephony Routing is changed by this feature to remove the need to create a fake Gateway in order to route to another domain. Instead a new option is added to the Sip Route Config page that allows the admin to select whether the entry is a Sip Route in its traditional sense (checking for a subscriber alias in another domain) or an actual route to another domain (where full translations are applied).

Figure 23: SIP Telephony Routes



The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile.

The following OPI methods would now contain the node/ logical entity names instead of the gateway route names.

- public void addTelephonyRoute (String domainName, TelephonyRoute teleRoute) throws ProvisionException;
- public void addTelephonyRoutes (String domainName, TelephonyRoute[] teleRoutes) throws ProvisionException;
- public TelephonyRoute[] getTelephonyRoutesByDomain (String domainName) throws ProvisionException;
- public TelephonyRoute[] getTelephonyRoute (String domainName, String routeName) throws ProvisionException;
- public void modifyTelephonyRoute (String domainName,String routeName,TelephonyRoute teleRoute) throws ProvisionException;

The TelephonyRoute object can also take a new Name Value: SIP Route Type (0 or 1). The absence of this assumes 0 which is the old way of doing SIP translations.

The two types are:

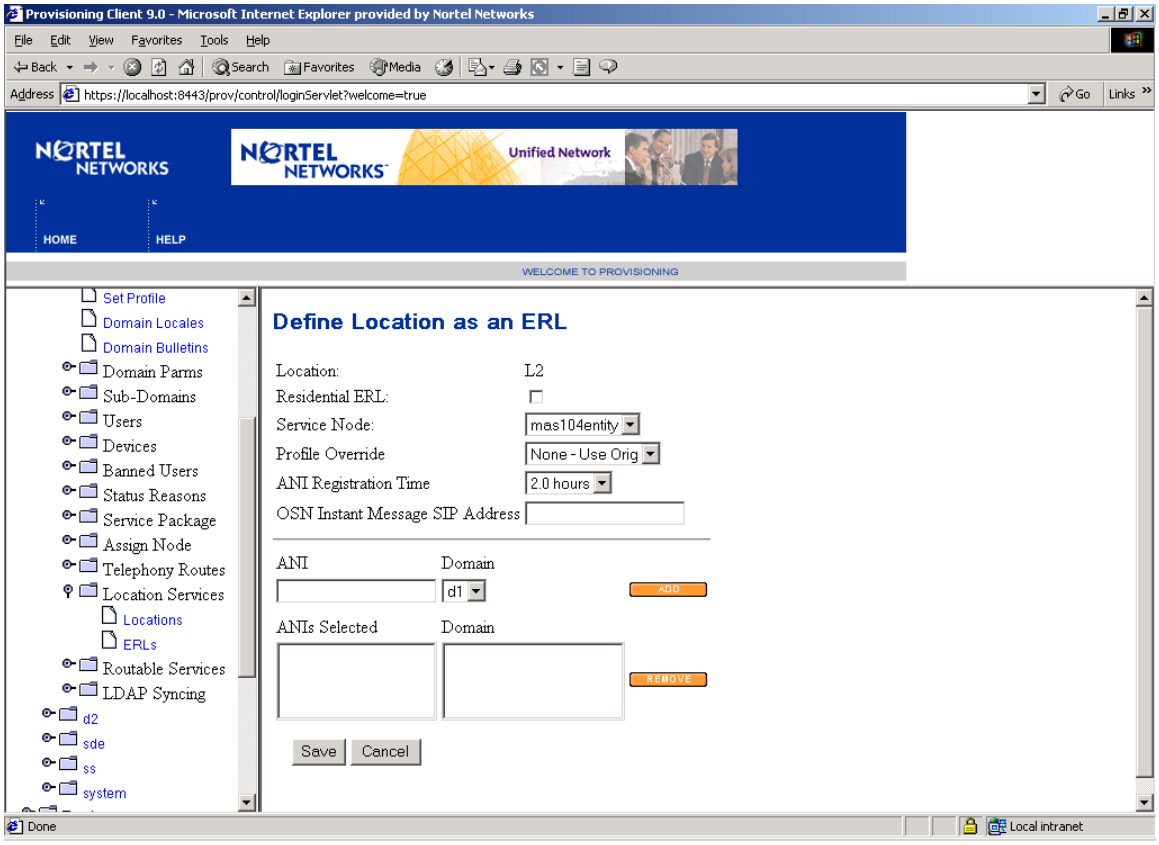
“Inter-Domain Alias Lookup” which maps to 0 and is the old way of SIP translations.

“Inter-Domain Routing” which maps to 1 and eliminates the need for the fake gateways.

102.5.10 ERL Provisioning

ERL provisioning required a gateway to be selected. This is changed to now select a node/ logical entity when creating an ERL.

Figure 24: ERL Provisioning



The OPI interface does not get affected as the existing methods and data objects would work and hence the change is backward comptabile.

The following OPI methods would now contain the node/ logical entity names instead of the gateway route names.

- public void addErl(String domain_name, String location_name, ErlInfo erlInfo) throws ProvisionException;
- public void modifyErl(String domain_name, String location_name, ErlInfo erlInfo) throws ProvisionException;
- public ErlInfo getErl(String domain_name, String location_name) throws ProvisionException;

102.5.11 Net6 IP Address

When creating a Service Package, Net6 service requires the operator to enter the IP address of the Net 6 box. Since this is a 3rd party box and would not be Re-IPed, this is not converted as part of the Re-IP feature.

102.6 Dependencies

NA

102.7 Faults

102.7.1 Logs and Alarms

A new alarm and log are added as part of this feature.

102.7.1.1 IPAddress change Log

Explanation

This log is generated when IPAddress is changed from Management Console. The details of the log are as follows:

Short Name: ADDR

Long Name: ADDRESS

Description: <<Logical Name>> IPAddress changed from <<OldIPAddress>> to <<NewIPAddress>>

102.7.1.2 Alarm

A new alarm is added as part of this feature. This alarm is raised when the service address of SM is changed from Management Console. The details of the alarm are as follows:

```
AlarmName: SM Service Address change

FaultNumber: 801

ShortFamilyName: SVCA

LongFamilyName: SMSVCADR

Severity: CRITICAL

ProbableCause: information modification detected

Description: System Manager service address changed

Corrective Action: Redeploy System Manager
```

102.8 Restrictions and Limitations

1. Solaris and RTP Media Portal only. 2K, MAS (Windows platform not supported).
2. Individual Server Re-IP required on each server. No central site.
3. No GUI for changing the server Re-IP.
4. This feature does not include any notification to the clients (PCC, Web or i200x phones) about the IP address change. Therefore after the change the clients will have to re-connect to their respective servers.

It is expected that this kind of activity will be done in a maintenance window and it is the Service Providers responsibility to inform the users of the outage if any.

103: Functional Description (FN): A00009831

103.1 Feature name and Feature ID

A00009831 - Patching

103.2 Description

103.2.1 Background

The delivery of emergency maintenance releases (EMRs) for the MCS product currently require tier 1 support groups to redistribute an entirely new load to the customer site. Since MCS 9.0 load sizes generally exceed 120MB, electronic distribution of the EMR can be delayed in situations where a high speed connection to the site is unavailable.

This feature provides the limited ability to create and deliver an EMR that represents a delta of the changes between the general release and the maintenance release. It is estimated that a typical “delta” EMR will be less than 3MB, and it can be transferred to a customer site over 56K dial-up in 10 minutes or less.

For the remainder of this document, the concept of an Emergency Maintenance Release "delta" is simply referred to as a “patch”.

103.2.2 Overview

This feature introduces a patch application utility that analyzes a delivered patch and applies it to the appropriate load for redeployment in the normal manner.

The following MCS patch capabilities are provided:

- Back-end (proprietary) tools are created to build a patch for a general load release. These are Nortel tools, and they are not delivered to the customer.
- A System Manager (SM) command line script is created to apply a delivered patch. The patch application script is a supplement to the other SM installation and deployment tools.

- A SM command line script is created to remove an applied patch. The patch removal script is a supplement to the other SM installation and deployment tools.

103.2.2.1 Cumulative Patch Content

Patches provided by this feature have cumulative content. This means that the content from all previously released patches are included in any newly released patch. For example, consider the following series of releases:

Initial Release (Maintenance Release 0): MCP_9.0.0.0

Patch 1: MCP_9.0.0.1

Updates the content of release MCP_9.0.0.0.

Patch 2: MCP_9.0.0.2

Includes and updates the content of patch MCP_9.0.0.1.

Maintenance Release: MCP_9.0.1.0

Updates the content of the initial release, and it includes the content of patches MCP_9.0.0.1 and MCP_9.0.0.2. The patch count is reset to zero.

Patch 1: MCP_9.0.1.1

Updates the content of maintenance release MCP_9.0.1.0.

...

Cumulative patch content is an important concept to remember when a new patch is applied or when an applied patch is removed. Applying a patch applies all content accumulated by all patches since the last maintenance release. Removing a patch removes all content accumulated by all patches since the last maintenance release.

103.2.3 Patch Generator

A patch generation tool is created by this feature. The patch generation tool is responsible for identifying the differences introduced by an emergency maintenance release and for bundling them into a compressed archive. The archive is made available to GNPS and Channel Management teams for delivery to the customer.

The patch generation tool is Nortel proprietary, and it does not represent a customer deliverable.

103.2.3.1 Capabilities

The generation tool is capable of creating a cumulative patch for any release of software against any base load. The content of a patch is not dependent on the physical name of the patch file, so GNPS and Channel Management are free to assign any naming convention that is relevant to the software delivery mechanism.

For this feature, the generation tool can only create patches for the Java-based components of the MCS product. Refer to “Limitations and Restrictions” on page 1034 for further information about patch generation capabilities.

103.2.3.2 Patch Content

A patch contains two types of data:

1. **Load Content**
   This represents Java byte code content of the MCS software. Only load content that has been added or modified is included in the patch.
2. **Meta Data**
   This represents any data that describes information about the patch context or contents. Meta data enables accurate unbundling and application of the patch.

Patch meta data includes (but is not limited to) the following critical pieces of data:

- **Patch Load Name**
  This meta data element identifies the release name of the patch.
- **Patch Base Load**
  The patch base load refers to the load updated by the patch.
- **Added File List**
  The added file list data element provides a listing of all files added by the patch (with checksum information).
- **Modified File List**
  A listing of all files modified by the patch (with checksum information) is provided by the modified file list element.
- **Legal README**
  This meta data defines legal information applicable to the patch. The content of this text is defined by GNPS, and its definition is outside the scope of this feature.
- **Patch README**
  This meta data defines installation information applicable to the patch. This might include identification about the network elements affected by the patch, special application procedures, or appropriate warnings. The content of this text is defined by GNPS, and its definition is outside the scope of this feature.

103.2.3.3 Patch Size

The goal of the generation tool is to create a compact patch file, but the nature of a maintenance release may necessitate that a patch file exceed the recommended 3MB maximum size. To better adapt to customer requirements, this feature does not restrict the size of a patch, and such considerations are left to the GNPS and Channel Management teams.

103.2.4 Patch Application

To apply a patch, this feature introduces a '`mcspatch.pl`' script that can be executed from the operating system command line of the SM.

103.2.4.1 Script Actions

The following actions are performed by the `mcspatch.pl` script:

1. Open the patch archive file and read the meta-data.
2. Present the user with the legal README text.
3. Provide the user with the opportunity to read the included installation README information.
4. Make sure the patch base load is installed. If not, patch application is aborted. The name of the base load is taken from the meta data.
5. Provide a brief summary and confirm the user's intent to install the patch. The summary includes:
   - patch creation date
   - base load name
   - patch load name
   - number of files added
   - number of files modified
6. Apply the patch to the base load. Existing patches are preserved in case the user requests removal ("back-out").
7. Present the user with the installation information.

Encountered errors abort application with an error-specific message and return code. Once applied, the patched load can be redeployed at the discretion of the administrator.

103.2.4.2 Command Line Syntax

The `mcspatch.pl` command line has the following GNU-style command syntax:

```
Usage: mcspatch [-qv] [--no-prompt] [--readme-legal]
             [--readme-patch] [--load-dir=dir] [--log=file]
             <patch-file>

Applies the patch identified by the <patch-file> argument.

Arguments:

   <patch-file>
      The patch to apply.

Options:
   --load-dir=dir
      Specifically defines the directory where the base load
      resides.  This option supports non-standard
installations
      where the name of the base load directory does not match
      the name of the base load itself.

   --log=file
      Indicates the log file used to record patch application
      output.  By default, the log file is
      /var/mcp/install/logs/mcspatch.<time> where <time> is
      replaced by HH-MM-SS.

   --no-prompt
      Apply the patch without prompting for confirmation.
      This option assumes acceptance of legal terms and no
      interest in reading the patch information before the
      patch is applied.

   -q
     Minimize standard output.  Complete information is still
      preserved in the log file.

   --readme-legal
      Displays the legal information and exits.  No patch is
      applied.

   --readme-patch
      Displays the patch information and exits.  No patch is
      applied.

   -v
      Maximize standard output.

   --version
      Displays version information and exits.  No other action
      is taken.
```

103.2.4.3 Example

The following is a simple patch application example:

```
 $ mcspatch.pl MCP_9.0.0.1.jar
```

103.2.4.4 Deployment

Once applied, the patched load is not automatically realized by components of the MCS system. For the patch to become active, the patched load must be re-deployed to all MCS components that require it. Load deployment is not covered by this document.

Since patch application is not incremental, only one patch can be applied at any given time. When a new patch is applied, the existing patch (if one exists) is replaced.

103.2.5 Patch Removal

To remove a patch, this feature introduces a '`mcsunpatch.pl`' script that can be executed from the operating system command line of the SM.

103.2.5.1 Script Actions

The following actions are performed by the `mcsunpatch.pl` script:

1. Determine if the specified load is patched. If not, abort execution.
2. Read the patch meta-data.
3. Provide a brief summary and confirm the user's intent to remove the patch. The summary includes:
   - patch creation date
   - base load name
   - patch load name
   - number of files added
   - number of files modified
4. Remove the patch from the base load.

103.2.5.2 Command Line Syntax

The `mcsunpatch.pl` command line has the following GNU-style command syntax:

```
Usage: mcsunpatch [-qv] [--no-prompt] [--load-dir=dir]
             [--log=file] <patch-name>

Removes the patch identified by the <patch-name> argument.

Arguments:

   <patch-name>
      The name of the patch to remove.

Options:
   --load-dir=dir
      Specifically defines the directory where the base load
      resides.  This option supports non-standard
installations
      where the name of the base load directory does not match
      the name of the base load itself.

   --log=file
      Indicates the log file used to record patch application
      output.  By default, the log file is
      /var/mcp/install/logs/mcsunpatch.<time> where <time> is
      replaced by HH-MM-SS.

   --no-prompt
      Remove the patch without prompting for confirmation.

   -q
      Minimize standard output  Complete information is still
      preserved in the log file.

   -v
      Maximize standard output.

   --version
      Displays version information and exits.  No other action
      is taken.
```

103.2.5.3 Example

The following is a simple patch removal example:

```
 $ mcsunpatch.pl MCP_9.0.0.1.jar
```

103.2.5.4 Deployment

Once a patch is removed, the base load returns to an unpatched state. This change is not automatically realized by components of the MCS system. To revert, the base load must be re-deployed to all MCS components that require it. Load deployment is not covered by this document.

103.2.6 Backing-out a Patch

No scripts are provided to specifically “back-out” a patch. Instead, patch back-out can be accomplished via one of two mechanisms:

1. Remove the existing patch and return the base load to an unpatched state.
2. Reapply a previously applied patch (the current patch will be overwritten).

Once backed-out, the load must be re-deployed to all MCS components that require it. Load deployment is not covered by this document.

103.3 Hardware Requirements or Dependencies

This feature does not require any hardware that is outside the scope of existing hardware platform requirements.

103.4 Software Requirements or Dependencies

This feature does not require any software that is outside the scope of existing installation and commissioning platform requirements.

103.5 Limitations and Restrictions

103.5.1 Patchable Components

This feature provides patch generation capabilities for most MCS Network Elements (NEs) running Java byte codes that can be deployed from the management console (or operating system command line) of the SM. Specifically:

- System Managers
- Fault-Performance Managers
- Accounting Managers
- Session Managers
- Provisioning Managers (except for Java Servlet Pages)
- IP Client Managers
- H.323 Gatekeepers
- RTP Portal / BladeCenter / Media Portal (Java component only)

Any component not specifically identified as “patchable” should be considered “non-patchable”.

103.5.2 Non-Patchable Components

The feature does not provide patch generation capabilities for the following MCS components:

- System Manager Console
- Media Application Server (MAS)
- Nortel Media Gateway 3200 (AudioCodes PRI Gateway)
- Provisioning Manager Java Servlet Pages
- Non-Java RTP Portal components
- Java Native Interface components
- All components provided by Installation & Commissioning.
- All operating system components.

Any component not specifically identified as “patchable” should be considered “non-patchable”.

103.5.3 Patch Applicator

The patch applicator script provided by this feature is designed to complement the installation and deployment scripts associated with the MCS SM. The patch application script is not intended for use as a standalone component. The application script provided by this feature is capable of running on any operating system where a MCS SM can be installed and deployed.

EMR application via the patching capabilities introduced by this feature is not necessarily consistent with other EMR application mechanisms.
The EMR application for all deployable MCS NEs is unified by this feature.

103.5.4 Custom Feature Delivery

This feature provides a mechanism for deploying an EMR to the customer site. It is not designed as a mechanism for interim release feature delivery (sometimes referred to as, "fast feature development"), and such use is not supported.

103.5.5 Data Schema Changes

This feature does not provide a mechanism to patch data schema or upgrade the customer database.

103.5.6 Maintenance Releases

The patching functionality provided by this feature is not a substitute for periodic maintenance releases. Furthermore, maintenance releases contain all patch content since the last maintenance release.

103.5.7 Patch Delivery

While this feature does not assume a specific patch delivery mechanism, continuation of the existing mechanisms is planned for MCS09. These mechanisms include:

- CDs
- ESDs (Electronic Software Delivery)

103.6 Interactions

N/A

103.7 Glossary

Term	Description
EMR	Emergency Maintenance Release (i.e. a “patch”)
GNPS	Global Nortel Product Support
MCS	Multimedia Communications System

Removal of DCE from default install and install wizards - A00009838

104.2 Description

DCE and DCE dependant applications on the SDM are being "MDed" in the SDM22/SN09 release. The DCE software will continued to be delivered with the CS2E00090 and CS2E00100 loads. The DCE Applications will be removed from the load as of the SDM24/SN11 release.

DCE will be removed from the list of commissioning tasks.

DCE software will be part of the SDM load and DCE user interfaces (‘sdmmtc->dce’ level) will still remain available to support existing DCE users. A note mentioning the DCE Manufacturing Discontinued will be displayed on the DCE user interface ().

105: Functional Description(FN): A00009839

105.1 Feature name and Feature ID

Ability to apply patches during ESUP upgrade - A00009839

105.2 Description

To equip ESUP with patching capabilities. There are three requirements for this feature. They are as follows:

- ESUP should be able to read and apply ".patch" files.
- ESUP should support patching along with regular upgrades.
- ESUP should also have an option of "patch only" upgrade, wherein user should be able to apply only patches (and not any other files).

Format for patch files has changed from SDM20. Prior to SDM20, the patch files used to be in IBM "bff" format with ".tape" as extension. From SDM20, after creating the patches they are tarred and zipped (gzip). The resulting patch files has an extension of ".patch".

105.3 Hardware Requirements or Dependencies

No new hardware dependencies has been introduced by this feature.

105.4 Software Requirements or Dependencies

With this feature ESUP will use the NTSimTool package to convert ".patch" files to ".tape" files.

105.5 Limitations and restrictions

None

105.6 Interactions

This feature brings some changes in user interactions. Please see the configuration section of this document.

106.1 Feature name and Feature ID

CBM IPSec Northbound Interface : A00009840

106.2 Description

This activity provides an easy-to-use IPSec configuration interface on the CBM for configuring IPSec/IKE parameters. This would be bundled as part of CLI tool of SSPFS for all SSPFS profiles.

This interface can be accessed only by the root user. No other users will be allowed to use this IPSec/IKE configuration interface.

This interface would accept user input values for various parameters related to the IPSec and IKE configurations. This interface will only support IPSec with IKE in preshared mode. No manual keying or certificate-based authentication will be supported by this CLI.

Following are the capabilities provided by the IPSec/IKE configuration interface

- Supports the option to save or edit changes
- Supports capability to abort configuration interface at any point of time
- All the configuration information would be automatically synchronized over to the mate system.
- This interface would generate configuration information for configuring IPSec on the downstream (for Solaris box). This information would be made available on the CBM in the /etc/inet/remotesystem/solaris directory as static file. The downstream would require to be manually modified to reflect this configuration information.[1] A sample downstream configuration file which would be generated by this interface is documented in the Appendix section of this document.

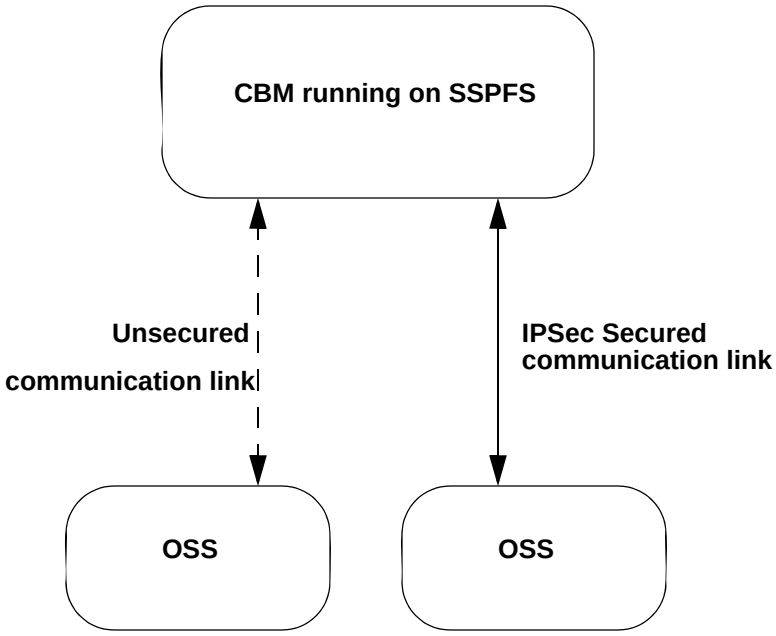
Details about the different parameters, valid options which would be accepted by each of these parameters and the configuration interfaces (snapshots) with examples have been documented in the CN section of this activity.

Figure 1 indicates a broad picture on the secure and unsecured communication between the CBM and the OSS. If IPSec communication is enabled between the OSS and the CBM, then the communication channel would be secure.

[1]**Warning :** This static file contains confidential information (related to the preshared key) and should be removed from the machine once its no longer needed.

Note: IPSec is used to provide additional security between OSS and CBM and is not meant to replace the use of standard secure protocols such as SSH, SFTP or HTTPS.

Figure 1 : Functional Layout



106.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies are introduced by this feature

106.4 Software Requirements or Dependencies

SN09 or later SSPFS load (with NTIpSec package) for the CBM.

The OSS should support IPSec for secure communication.

106.5 Limitations and restrictions

This activity only supports IPSec in Transport Mode.

IPSec Tunnel mode configuration would not be supported as part of this activity.

106.5.1 Security

For secure communication, all security parameters provisioned on the OSS must match with security parameters provisioned on the CBM.

106.5.2 IP Addresses

Only IPv4 (32 bit) addresses will be supported

106.5.3 Keys

Only Preshared keys would be used for IKE communication.

106.5.4 Test Strategy

- The OSS which would be tested in this activity would be a solaris 9 machine.

106.5.5 HA system key negotiation

IPSec or IKE SA's will not be replicated on HA CBM's. There would be loss of communication for inbound connections (from OSS to CBM) post CBM fail-over, until the existing IPSec SA's expire and IPSec SA's get re-negotiated.

This issue could become prevelant again if the OSS is an HA platform and it fails over.

106.6 IPSec Precedence Order

When there are numerous IPSec policy entries in the IPSec configuration file, the system could resort to reordering of the policy entries or attach precedence to some rules defined in the IPSec configuration files. This can happen in the following conditions.

If the new policy entry has been defined with action bypass ("action" attribute can take in values drop, ipsec and bypass), then this entry would be attached the highest precedence. If there are more than one bypass entries, the system would match all the bypass entries before matching any other entries.

If there are IPSec configuration entries with matching entries for the input and output datagrams, then the first such kind of a match would be taken.

In case of matching entries for input and output datagrams, the policy entries would be reordered (adding the new entry before the old entry) if the new policy entry has a higher level of protection strength than the old entry.

The strength of the policy entries would be defined as

AH and ESP > ESP > AH

Entries with both the AH and ESP present in the policy entry would be ordered before entries with AH-only and ESP-only entries.

For other entries, the order specified by the user would not be modified, newer entries are added at the end of all the old entries.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry.

106.7 Interactions

106.9 Appendix A for A00009840

This interface would generate configuration information for configuring IPSec on the downstream (for Solaris box). This information would be made available on the CBM in the /etc/inet/remotesystem/solaris directory as static file. The downstream would require to be manually modified to reflect this configuration information. Following section provides snippets of downstream configuration files.

106.9.1 Sample IPSec downstream configuration file (downstream.ipsec)

The following new rule should be added into the ipsecinit.conf file on the downstream in the similar format. This file is available in the directory /etc/inet and this instruction is applicable only for a solaris (sspfs) box

{ laddr 47.135.214.62 raddr 47.135.214.130 dir both } ipsec { encr_auth_algs sha1 encr_algs 3des auth_algs sha1 }

106.9.2 Sample IKE downstream configuration file (downstream.ike)

The following rule below needs to be added into IKE config file on the downstream in the similar format. This file is available in the directory /etc/inet/ike and the file to be updated with the below changes is config. This instruction is applicable only for a solaris (sspfs) box.

{

label Newrule

remote_addr 47.135.214.130

local_addr 47.135.214.62

p2_pfs 2

p2_lifetime_secs 400

p1_xform { oakley_group 2 auth_method preshared encr_alg 3des auth_alg sha1 p1_lifetime_secs 400 }

}

The following key information should be updated on the file ike.preshared in the directory /etc/inet/secret on the downstream. This instruction is applicable only for a solaris (sspfs) box. This key information should be matching with the above added IKE rule

{

localidtype IP

localid 47.135.214.62

remoteidtype IP

remoteid 47.135.214.130

key 12333895734895abc23489237489723

}

107: Functional Description(FN): A00009865

107.1 Feature name and Feature ID

A00009865: Add MCP820 supporting on SAM21 EM SN09 release

107.2 Description

107.2.1 Feature Functionality

In the SN09 release, there will be a new kind SC card (i.e. MCP820) introduced into SAM21 shelf. MCP820 card is a Motorola card with 512M memory. Since the load image files for each type card are different, each build of SC load RPM in SN09 release will include two image files, one for each.

This feature includes the upgrade job on the SAM21 EM side. Currently, EM only supports one kind of SC and selecting one image file during the provision. and memory requirements definition for the applications.

107.2.1.1 MCP 820 card function list

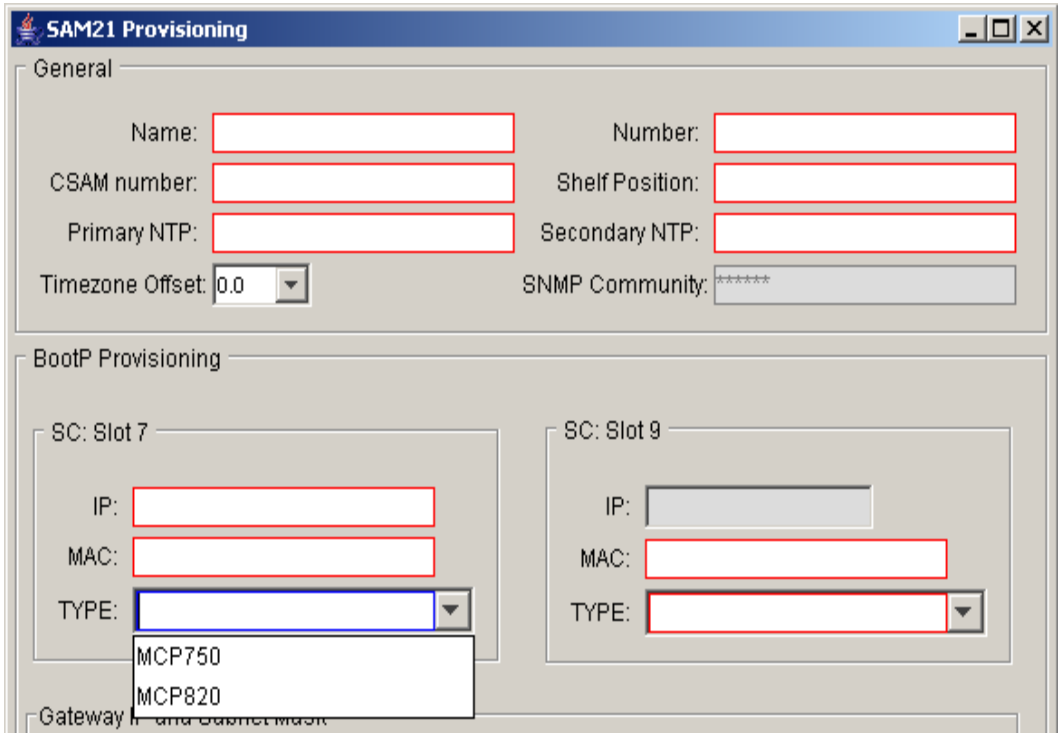
Table 1 MCP820 memory/funtion list

Card Type	Memory Size	Function
MCP820	512M	SC

107.2.1.2 Provision/Re-provision a shelf

In SN09 release, there are two drop list added for each SC card type selection in the provision window.When provisioning or re-provisioning a shelf, the User needs to choose the right type for each slot and can not leave it blank. The look of shelf provision window is shown in Picture 1:

Picture 1: the new look of shelf provision window



107.2.1.3 The change of SC bootp entry in the /etc/bootptab file

There are two bootp entries for two SC cards in the /etc/bootptab file. SC will find the entry when it boots from the network. In SN08 and before version, the value of “bf” item, boot file name, will keep the same as the SC load version for these two entries. In SN09 release, the value will be different if the SC card type is not the samd. For a MCP750 card, the value of “bf” will keep same as SC load version; for a MCP820 (or other type SC card introduced in the future) card, the value will be “SCLoadVersion.CardType”. The sample shows below:

47.142.114.238 stands for a MCP750 card, and 47.142.114.239 stands for a MCP820 card.

108.1 Feature name and Feature ID

ACTID A00009890

Provisioning for Media Proxy insertion for SIP lines

108.2 Description

In SN09 SIP lines will be supported on the CS2k via a new component, the Session Server (aka ‘Phoenix’), which is based on re-use of various MCS components. It is necessary to allow SIP Lines to reside in private VPNs, as is already provided for fixed VOIP line gateways and CICM terminals. This is achieved by appropriate Media Proxy insertion by the CS2K. This feature provides the provisioning necessary to support Media Proxy insertion for SIP lines.

During a call, the VPN ID of a SIP line will be determined by the Session Server (via a mapping of ‘Location ID’ to ‘Routability Group’), while the VPN ID of a fixed VOIP/CICM line is determined by the GWC, via SESM provisioned IP-VPN(NAT) Network Zones and ‘Distributed VPNs’. Hence in order to allow correct comparison if the VPN IDs at the two ends of a call and Media Proxy insertion if required, the VPN IDs in GWC and Session Server must be consistent. This feature ensures that both the GWC and the Session Server have the same VPN ID information to allow the correct insertion of Media Proxies, by flow-through provisioning of IP-VPN(NAT) network zones and Distributed VPNs from SESM to the Session Server.

Data synchronisation is managed by the CS2K Audit, for cases in which the SESM and Session Server data are inconsistent and for commissioning support.

Example flow-through case: To create a IP-VPN(NAT) Zone.

- Use the SESM GUI to add a new IP-VPN(NAT) Zone named “maidenhead.com”.
- If a Session Server(MCS-EM) is configured into the SESM an add Routability Group request is sent to the Session Server via the OPI interface.
- On a successful response from the Session Server, the SESM will allow the IP-VPN(NAT) Zone to be created and displayed to the user.

Related activities are:

- ACTID xxxxx MP insertion for SIP lines OPI changes on Session Server(MCS-EM)
- SN09 feature A00008522, SESM Support for SIP Lines, which implements the SIP Proxy on SESM
- SN09 feature A00007217, OAM-Itrans Media Proxy Selection

Hardware Requirements or Dependencies

Not applicable

108.3 Software Requirements or Dependencies

Session Server OPI version 9.0 software (OPI version allows Routability Group ID's)

108.4 Limitations and restrictions

Multiple CS2M Configuration managers should not connect to a single Session Server(MCS-EM). The result of this would mean that a shared IP-VPN(NAT) Zone would not be allowed to be provisioned into the 2nd to nth CS2M Configuration managers and hence omit the 2nd...nth CS2Ks from having gateways/endpoints provisioned within the shared IP-VPN(NAT). This is not a supported configuration for SN09 release.

108.5 Interactions

For customer deployments where a Session Server is introduced into the CS2k for SIP Lines functionality, this feature will enforce data synchronisation between the SESM and Session Server. Where data synchronisation fails, an alarm will be generated to inform the customer.

The existing funtionality of creating a IP-VPN(NAT) Zone and creating a Distributed IP-VPN (NAT) Zone will only succeed if the Session Server accepts the flow-through provisioning data from the SESM.

e.g. If the flow-through provisioning of the IP-VPN (NAT) Zone information to the Session Server fails this will cause the creation of the IP-VPN (NAT) Zone to fail on the SESM.

The existing funtionality of the CS2K data audit, will also attempt to synchronise the data between the SESM and the Session Server.

109: Functional Description(FN): A00009893

109.1 Feature name and Feature ID

Session Server Call Processing Overload

109.2 Description

This feature provides enhancements to the Session Server SIP Gateway Application overload functionality that was introduced by the SN08 feature A00007270, Session Server Call Processing Overload.

A00007270 used an overload detection scheme that was based solely on the depth of two call processing messaging queues - the Generic Control Protocol (GCP) queue used for CS2K-originated calls and the Session Initiation Protocol (SIP) queue used for remote SIP server- originated calls. If either queue was determined to be above its threshold at the end of a sampling period, the application was put into an overload state.

Once the application was in overload, all new incoming calls received from a remote SIP server were rejected. This call rejection continued until the results of a subsequent sample period indicated the queue sizes had decreased below the overload threshold.

A few areas of note regarding SN08 application overload detection:

- The amount of work being done by the CPU (the CPU occupancy) was not a factor in determining whether the application was in overload.
- When the application was in overload, all new remote SIP server calls were rejected. There was no throttling mechanism that would have allowed some new SIP calls to continue to be processed while the application attempted to come out of overload.
- Since only new remote calls were rejected, a server that handled a higher proportion of local originations (i.e., calls from a CS2K) got little or possibly no overload relief using the SN08 overload handling mechanism.

An overview of the new functionality provided by this feature for SN09:

- For **Overload Detection**, CPU occupancy is now a factor in the algorithm for determining overload.
- For **Flow Control**, instead of blocking all new SIP originations during overload, new calls - both CS2K-originated and remote SIP server-originated - will be throttled to allow a certain percentage of both call types to complete.

- **Babbling Node Detection** - Provides the ability to detect and limit the impact of a remote SIP server that is sending an excessive number of bad messages to the Session Server.
- **Overload Monitoring and Fault Management** - New OMs, logs and alarms are created for the purpose of providing information regarding CPU occupancy, queue sizes and percentage of calls that are being rejected.

109.2.1 Overload Detection

For SN09, in addition to getting periodic samples of each of the call processing queue sizes, the CPU occupancy is also checked at the same time. At the end of each sampling period, the SIP Gateway Application is considered to be in overload if at least **one** of the following conditions exists:

- CPU occupancy exceeds its overload threshold
- GCP queue length exceeds its overload threshold
- SIP queue length exceeds its overload threshold

If the application is found to be in overload, a major alarm is generated along with a SIPC310 log (SN08 functionality).

The application can also be in a pending overload state, meaning it is either approaching overload or possibly receeding from an earlier overload condition. Again, the application is considered to be in an overload pending state if at least one of the following condistions exist:

- CPU occupancy exceeds its pending threshold
- GCP queue length exceeds its pending threshold
- SIP queue length exceeds its pending threshold

There are no changes to call processing while in the pending state, unless the application is in the early stages of recovering from overload. In the latter case, some calls may still be getting rejected. This is discussed in more detail in the Flow Control section.

As in SN08, when the application is in pending overload, a minor alarm is generated, along with a SIPC310 log.

109.2.2 Flow control

Once the application has entered the overload state, new call originations are throttled as a means of easing the load on the CPU. The level of throttling is determined by the Flow Control Rate (FCR). FCR is analogous to the percentage of new calls allowed to complete while the application is in this condition. This percentage is applied to both local (CS2K-originated) and remote (SIP-originated) calls. In other words, if the FCR is 90, 90% of new local calls and 90% of new remote calls are allowed, or every 10th call of each type is rejected. Calls in progress are not affected in any way.

When the system goes into overload an initial FCR value is calculated, causing a certain percentage of calls to be rejected. For each subsequent sample period the FCR can fluctuate between 0 (all calls blocked) and 100 (no calls blocked), based on the current overload state.

If conditions improve and a sampling period indicates the application is no longer in overload, the FCR is not immediately returned to 100%. Instead, a gradual increase each period is done to ensure the system does not bounce back into overload.

For call rejection, a Local Release with Cause Value of 42 is sent for GCP originations and a 503 Service Unavailable is sent for SIP originations.

In SN08, when the SIP Gateway application was in overload it responded to a SIP OPTIONS request with a 503 Service Unavailable response. The purpose of this was to indicate to the remote server that the Session Server was no longer accepting any new calls. If the far end reacted appropriately to this reponse, it would stop sending new calls to the overloaded Session Server.

With the changes in this feature that now allows for a certain percentage of calls to complete during overload, the 503 response will no longer be sent in response to an OPTIONS request when the application is in overload.

109.2.3 Babbling Node Detection and Isolation

This component provides the ability to detect and limit the impact of a remote SIP server IP address that is flooding the Session Server with an excessive number of bad syntax messages. Once an IP address is labeled as a babbling node, lower level software intercepts all messages from the node before they reach the application, thereby freeing the application from the time it would have to spend processing each message.

Babbling node detection involves keeping a count of the number of SIP messages with bad syntax received from an IP address. Every 5 seconds, this counter is scanned for each IP address. If the number of new bad messages received from an IP since the last check exceeds the threshold value, the address is removed from service in such a way that no further messages from this IP are processed by the application.

Note that in order to determine the source (the remote SIP server) of a bad syntax message, the Session Server must at a minimum be able to parse the SIP via header. If the via header is too corrupted for parsing, the message will not be counted as a bad syntax message.

Babbling node isolation is implemented by using the Linux iptables functionality. When a node is determined to be babbling it is marked in iptables in such a way that all messages from the IP will be discarded. No responses are sent to the remote node. In the session server, the connection

status of the remote SIP server is marked inactive and all access links mapped to the server are removed from service. Corresponding trunks in the CS2K are put into a SYS state. This effectively disables all incoming and outgoing calls from the server.

After the IP has been disabled for 5 minutes, it's status in the iptables is changed so that its messages are no longer dropped and the associated access links/trunks are brought back into service. The same criteria are again used to detect and isolate the IP if it continues to send an excessive amount of SIP messages with syntax errors.

109.2.4 Overload Monitoring and Fault Management

As a means of providing the ability to monitor overload-related events and statistics, new Operational Measurements, logs and alarms are created by this activity.

A new OM group, SIPGW_OVERLOAD, contains information related to the level of usage for each of the monitored resources (CPU, GCP queue, SIP queue). The following types of registers are in the group:

- CPU occupancy calculation from the latest sampling period
- GCP queue size from the latest sampling period
- Radvision queue size from the latest sampling period
- High water marks for each resource over a 30 minute period. Reset to 0 every 30 minutes.

Below is a sample output of the new OM group SIPGW_OVERLOAD:

```
Active Register Counts
START Thu Feb 10 10:30:00 2005   STOP Thu Feb 10 10:31:44 2005

OMGROUP: SIPGW_OVERLOAD
*****************************************************************

TUPLE KEY: 0            TUPLE KEY NAME:

Register Name                          Value
-------------------------------       ----------
CPU_OCCUPANCY                              45
CPU_OCCUPANCY_HWM                          67
GCP_QUEUE_SIZE                             15
GCP_QUEUE_SIZE_HWM                         29
SIP_QUEUE_SIZE                             25
SIP_QUEUE_SIZE_HWM                         30
*****************************************************************
```

In addition to the OMs, three new STGW700 logs are added to cover various scenarios:

- Changes in the Flow Control Rate. Note that this log can be generated when the application is not in overload, such as when it is still recovering from an earlier overload state.
- When an IP address is either removed from or re-added to the Access Control List as a result of babbling node isolation.
- When a critical, major or minor CPU occupancy level has been reached.

Per existing functionality, a minor alarm is raised when the application is in a pending overload state and a major alarm when in overload. These remain unchanged.

Note the minor and major CPU alarms can be activated even if the application is not in overload.

Here are examples of the new logs:

```

109.3 Hardware Requirements or Dependencies

No new hardware requirements or dependencies.

109.4 Software Requirements or Dependencies

No new software requirements of dependencies.

109.5 Limitations and restrictions

In addition to the normal, 5 minute timeout, disabled babbling nodes are re-enabled in the following situations:

- When Remote SIP Server configuration data is changed in the Session Server.
- When the Session Server is suspended. Upon unsuspension the IP will be enabled.

- When the Session Server switches activity to the other unit.

In order to count the number of bad syntax messages received from a remote SIP server for babbling node detection, the Session Server must be able to parse the SIP via header in the offending message to determine the sender of the message. Without the source IP address, the bad message cannot be counted against a server.

109.6 Interactions

In SN09, the 503 response will no longer be sent in response to an OPTIONS request when the application is in overload.

When Access Control List (ACL) functionality is activated, babbling node message discarding using iptables takes precedence over the ACL iptables setting. In other words, if the ACL iptables setting allows messages from an IP to be received, but the node was found to be babbling, all messages from the IP will be discarded until the babbling node timeout. At that point, the ACL setting determines what to do with messages from the IP.

109.7 Glossary

Term	Description
ACL	**Access Control List** - the list of allowable IP addresses from which the Session Server can receive messages.
FCR	**Flow Control Rate** - the percentage of new call originations allowed while in overload or during the recovery period when the application is coming out of overload.
GCP	**Generic Control Protocol** - call control protocol used between the gateway controller and the session Server.
SIP	**Session Initiation Protocol** - an application-layer protocol for creating, modifying and terminating sessions with one or more participants.

110: Functional Description(FN): A00009905

110.1 Feature name and Feature ID

A00009905 – Private and Public Name and Number Display

110.2 Description

MCS09/SN09 Private and Public Name and Number Display feature is introduced for the MCS platform that allows the MCS to deliver the **Calling** Private or Public Name/Number based on a set of rules***. The Calling Private/ Public Name and Number Display has been common a feature for TDM Centrex Networks where groups can exchange Private Name and Numbers within a group, but provide Public appearance when calling party is outside the Centrex group.***

110.3 Introduction

This feature will introduce the TDM Centrex concepts of Private/Public Name and Number display when SIP domains are involved and when parties from SIP domains are involved with TDM parties that are an extension of the same group. For example, a Centrex group where some of the members reside on the TDM network and some of the members reside in the SIP network. This will allow the calling parties in the SIP Network to deliver Private Name and Number to the TDM group members and provide Public Calling Name and Number to PSTN users. Similarly, the TDM Centrex group can deliver the Private Calling Name and Number to the SIP network users.

The MCS behavior today is that the private name of the MCS subscriber is delivered regardless of where the terminator is located. The private number is delivered to the terminator only when Private Gateway Telephony routes are used.

This feature will also provide a way to restrict direct SIP inter-domain calls. This restriction could be added when users from one domain cannot use "Name Dialing" to reach another user. For example, a user in domain A.com is calling a user in B.com by either using an MCS alias or SIP user ID.

New parameters will be added to the MCS Provisioning System to provision the Public Name and Number.

110.3.1 Feature Activation

Provisioning the public name or number in the domain hierarchy tree activates this feature. Without provisioning a public name against a domain the private name is delivered based on the call scenario. If a public number is not provisioned either against a domain the private number or SIP user ID is delivered based on the call scenario.

110.3.2 MCS Private Call

Within a TDM network a “Private call” is considered a call within a Centrex group where the subscriber’s “Private” name and number are delivered to the called party. This number could be an extension like a 4 or 5 digit number. The equivalent of Centrex group on the MCS system is a domain or sub-domain. Subscribers within an MCS domain or sub-domain can setup translations to deliver the private name and number to their TDM Centrex group, but provide the public appearance to other domains and TDM terminations. Within MCS a call is considered private if the following rules apply and this feature is activated:

1. The originator and terminator of the call are in the same domain hierarchy tree. This is the case where the originator is a known MCS subscriber. The MCS subscriber could be a CD2 or a non-CD2 user.
2. Incoming call party from the Gateway and the terminator are in the same domain hierarchy tree. This is the case where the originator of the Gateway is not known, but the Gateway is using the same domain hierarchy tree as the terminator of the call.

The rules would apply to basic calls, calls that are forwarded or transferred within the MCS or to TDM users.

110.3.3 MCS Public Call

Within the MCS system a “Public call” is a call that is made outside the domain hierarchy boundaries. This could be another domain or Gateway that is reached using public translations. For example, to call a PSTN subscriber a public Gateway route is used for termination and in this case the MCS subscriber’s public name and number will be delivered. The following rules for a Public Call would apply when this feature is activated at the MCS domain level:

1. The originator and terminator are in different hierarchy tree. This includes domains supported by the MCS system and foreign domains located on other systems.
2. Incoming calling party from a Gateway is in a different domain than the terminating domain root tree.

The rules would apply to basic calls, calls that are forward or transferred within the MCS or to TDM users.

110.3.4 MCS Private Calling Name and Number

The “Private” calling name and number assigned to a subscriber are provisioned by the MCS Provisioning Server Administrator. The subscriber’s name is a mandatory field that is provisioned when adding a new subscriber. The first and last names of the subscriber are used to create the private name. A subscriber can only be assigned a single “Private” name.

The “Private” calling number is an optional field that is assigned to the subscriber and is referred to as the “Private Charge ID” for provisioning purpose. This field is used for calling line number display and in some cases for billing purposes. Only a single “Private” calling number can be assigned to a subscriber.

110.3.5 MCS Public Calling Name and Number

On the MCS a “Public” calling name and numbers are NOT assigned to a subscriber, but to domain/sub-domain and are available to subscribers within that domain/sub-domain. Based on the call scenario, the MCS will select the domain’s public name and number on behalf of the calling party. If a domain tree hierarchy is present a sub-domain can use a parent’s public name and number if the following rule applies:

- If a public name is **NOT** provisioned for the sub-domain, the application server checks if there is a public name provisioned for the parent domain. If one exists, public name is delivered for inter-domain and PSTN calls.
- If a public number is **NOT** provisioned for the sub-domain, the application server checks if there is a public number provisioned for the parent domain. If one exists, public number is delivered for inter-domain and PSTN calls.

There is an exception to the rules above when Gateway or SIP Telephony routes are involved. A Gateway or SIP Telephony route can override the call type based on the type of route. A Gateway/SIP Telephony route can be provisioned as a “Private” or “Public” route.

If the public name for an originating domain or sub-domain is provisioned and applied the following changes will be made:

1. Replace the calling party’s display name with the public name.
2. Remove the picture ID of the calling party
3. The connected name display of the originator is removed.

If the public number for and originating domain or sub-domain is provisioned and applied the following changes will be made:

4. The calling party’s number is replaced with the domain public number.
5. The originating client’s SIP User Agent is removed.

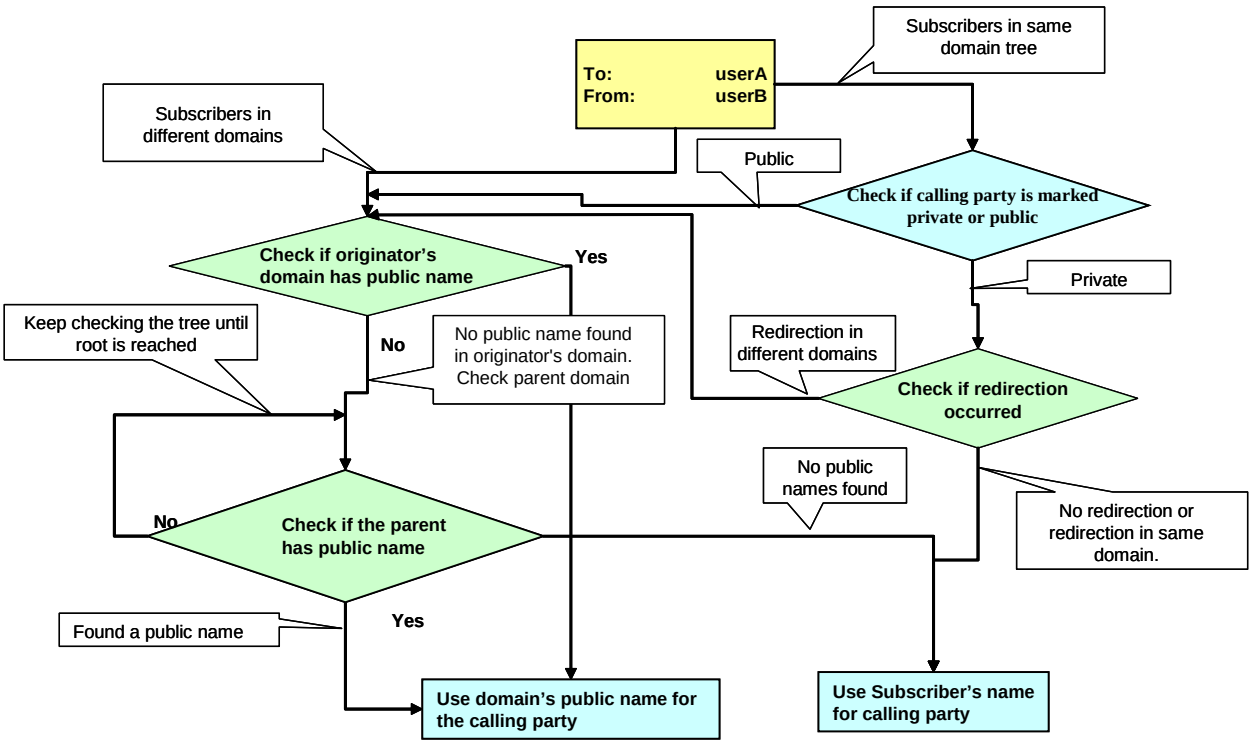
6. The SIP Contact header is replaced with the domain public number

Note: Note: MCS public calling name and number are is applied to intermediate parties when redirection occurs and it only applied to the calling party. One example is when user (A) in domain A calls another user (B) in the same domain and B redirects the call to C in a different domain. In this case Public Name/Number is applied to the calling party (A) only and to the redirecting party (B).

110.3.6 Determining Public/Private name and number

The following diagram provides a high level flow of determining the calling Public/Private name when using SIP User IDs or SIP Aliases to call a user in the same or different domain.

Figure 1 Name lookup for direct SIP inter-domain calls



The following diagram provides a similar flow of when calls are made from a domain to a Gateway.

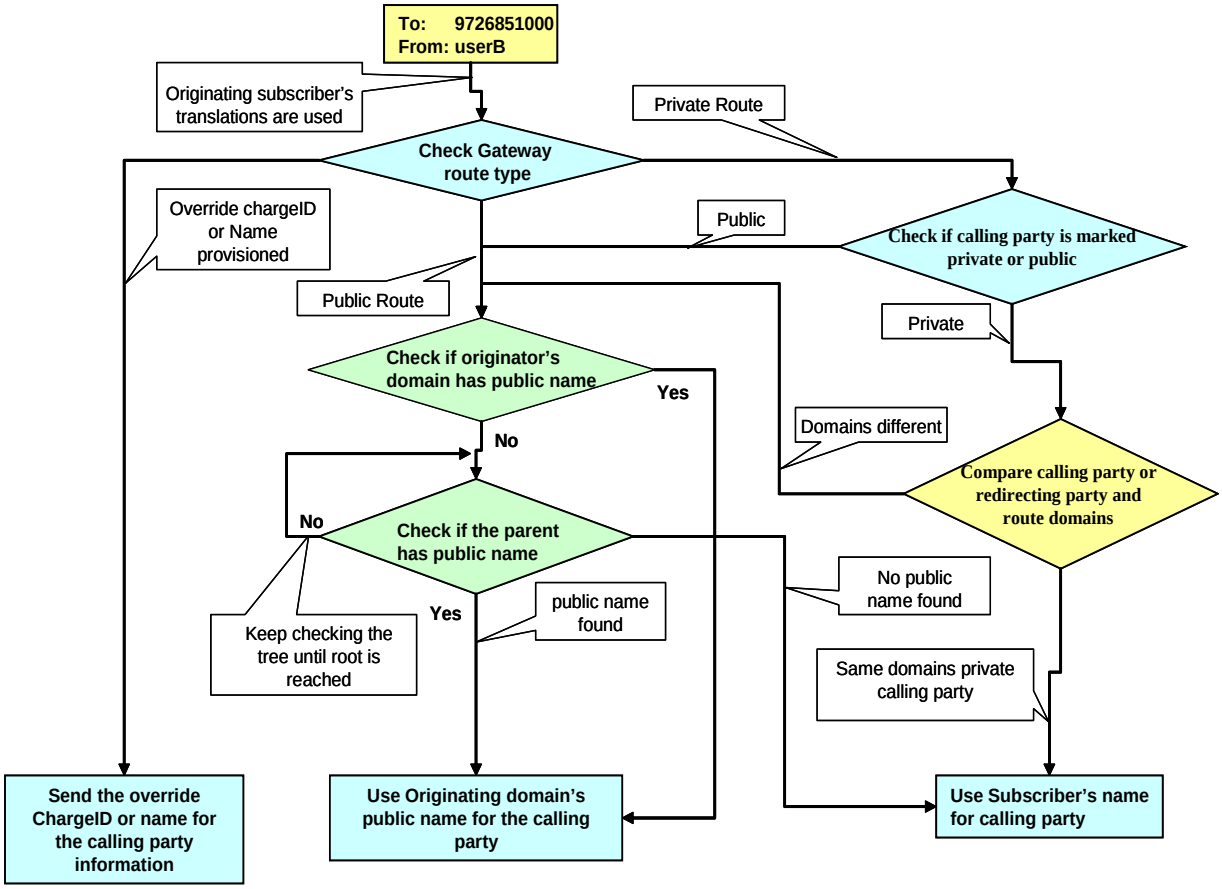


Figure 2 Name lookup Gateway routed calls

Note the both flows only show how the public/private name is found, but the same rules apply to the public/private number as well.

110.3.7 Scenario matrix

110.3.7.1 Direct SIP calls

The following sample call matrix provides the display of name and number or SIP User ID between Non-Converged Desktop calls when this feature is activated. In the Direct SIP calls domain "A" calls between itself and another domain "B". Calling Party for the Gateway scenarios in the columns below show what the call type is tagged as when the MCS receives the call from the Gateway.

#	Calling Party	Called Party	Calling Client Display	Called Client Display
Direct SIP calls				
1	Domain A	Domain A	Private	Private
2	Sub-domain in A	Different Sub-domain in A	Private	Private
3	Domain A	Domain B	Public	Public
4	Sub-domain in A	Sub-domain in B	Public	Public
Outgoing Gateway calls				
6	Domain A	Domain A's Gateway route (Private)	Dialed digits	Private
7	Domain A	Domain A's Gateway route (Public)	Dialed digits	Public
8	Domain A	Domain B's Gateway route (Private)	Dialed digits	Private
9	Domain A	Domain B's Gateway route (Public)	Dialed digits	Public
Tandem Gateway calls				
11	Private	Outgoing Gateway route (Private)	Dialed digits	Private
12	Private	Outgoing Gateway route (Public)	Dialed digits	Public
13	Public	Outgoing Gateway route (Private)	Dialed digits	Public
14	Public	Outgoing Gateway route (Public)	Dialed digits	Public

Figure 3 Calling party display for SIP calls[1]

110.4 Gateway calls

The following matrix provides the Converged Client and Converged Phone displays when using Converged Desktop service with this feature:

[1]The assumption in the table is that both domains have public name and number provisioned.

#	Calling Party	Called Party	Calling PAD Display	Calling Client Display	Called PAD Display	Called Client Display
Complex CD calls						
1	Centrex CD phone	Centrex phone	Dialed digits	No pop up	Private	N/A
2	CD - from PCClient (C2C)	Centrex phone	Calling Party's Private Number.	No pop up	Private	N/A
3	CD - from Centrex phone	CD Centrex phone	Dialed digits	SIP User ID	Private	SIP User ID
4	CD - from PCClient (C2C)	CD Centrex phone	Calling Party's Private Number.	SIP User ID	Private	SIP User ID
5	Centrex	CD Centrex phone	Dialed digits	N/A	Private	Private
6	CD - not in CD mode	Centrex phone	N/A	Dialed Digits	Private	Public Number
7	Centrex	CD - not in CD mode	Dialed digits	N/A	Private	Private
8	PSTN	CD Centrex phone	Dialed digits	N/A	Public	Public
9	CD - from Centrex Phone	PSTN	Dialed digits	N/A	Public	N/A
10	CD - from PCClient (C2C)	PSTN	Calling Party's Private Number.	N/A	Public	N/A
11	CD - not in CD mode	PSTN	Dialed digits	N/A	Public	N/A
Simplex CD calls						
12	CD-Centrex	CD-Centrex	Dialed digits	SIP User ID	Private	SIP User ID
13	Centrex	CD-Centrex	Dialed digits	N/A	Private	Public Number
14	PSTN	CD-Centrex	Dialed digits	N/A	Public	Public

Figure 4 CD client/PAD Display

Notes :

1. CD calls from the PC client assume that click to call is used.
2. Calling PAD Display assumes that the connected name and number are not available.

Note: domain mapping differs on the Gateways supported by MCS. CS2k sends a Nortel proprietary header to map domains to the incoming requests. AudioCodes gateways use direct domain mapping to the MCS domains.

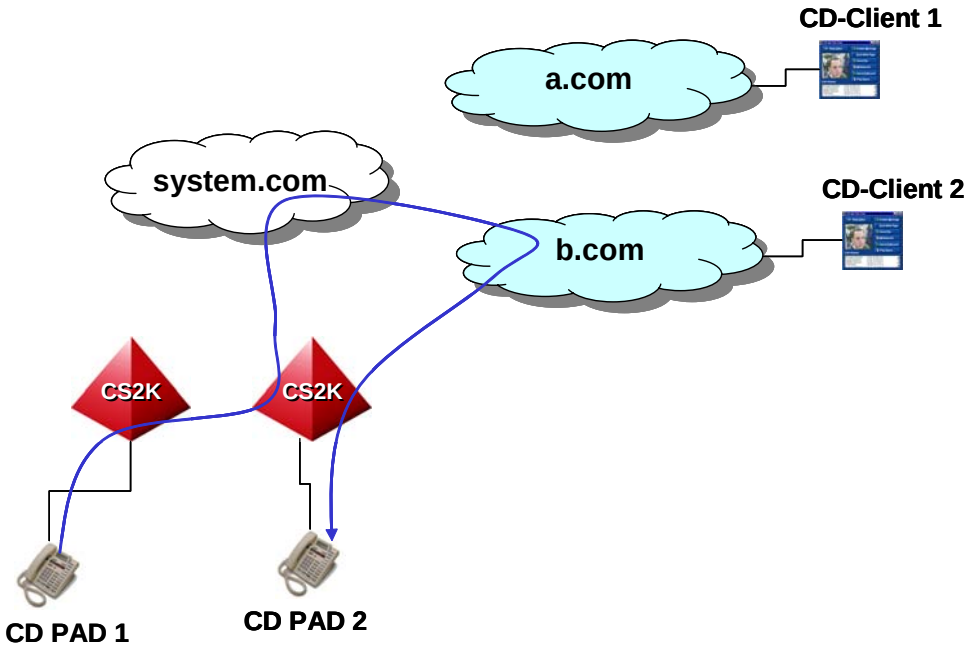
110.4.0.1 Calls that involve multiple domain hops

In some scenarios incoming calls from a Gateway could hop multiple domains before reaching the final destinations. In these scenarios public name and number of the calling party could change based on domain's public name and number provisioning. The following rule applies for changing calling party's name and number for incoming Gateway calls that could route to other domains or Gateways:

1. *Incoming requests from the Gateway look up the public name and number of the calling party only if the calling party is known at the MCS. Converged Desktop 2 is one of scenarios where calling party is known at that MCS.*

2. *If the incoming request traverses a SIP inter-domain or a Gateway route the route can override the calling name and number.*

Since Converged Desktop is the only feature known where PSTN subscribers are also known at the MCS the following example provides a call behavior. The following figure applies rule #1 above in an example of a CD2 subscriber in one domain (a.com) calling another CD2 subscriber in a different domain (b.com). The incoming request from the terminating switch is received in a common domain (system.com) and then forwarded using SIP inter-domain translations to terminating domain (b.com). Since the originator is in a different domain (a.com) than the terminating subscriber, and domain a.com has a public name/number provisioned – domain a.com's public name/number is delivered to CD2 PAD/Client.



If the originator of the call is not known, and the incoming request passes from one domain to another the calling party information is not changed unless the inter-domain routes force a change through provisioning.

110.4.1 MCS Connected name and Picture ID

MCS connected name and picture ID is a feature which provides the originating user the "Display name" and picture ID of the terminating party when the terminating party is ringing or has answered the call. This feature is also available when sending IM and using collaboration. The public name and number provisioning at the terminating domain will change how the connect name and picture ID are displayed to the originating client if the originating client is in a different root domain. If the terminating party has public name provisioned in its domain tree the originating domain will not receive the

connected and picture ID or the terminator. In addition the picture ID will not be available to the originating client if the originator puts the terminator in its personal address book.

110.4.2 Public Name and Number and IM and Collaboration

If public number is provisioned for an originating domain the originating client can send an Instant Message (IM), push a Web Push or start MCS Collaborations. The terminating client is unable to reply to and IM, send Web Push or reply to Collaboration attempt because the identity of the originator is replaced with the public number. The terminating client can send an IM, Web Push to request for Collaboration if the terminating user knows the originator's user ID (e.g. user@domainA.com).

If only public name is provisioned within a domain tree then IM, Web Push and MCS Collaborations between the originator and terminator will continue to work. But the display name and picture ID are removed from the call.

110.4.3 Interactions with Converged Desktop (CD)

In a Converged Desktop configuration Voice could be provided by Centrex group lines from a TDM switch, but multi-media and advance routing capabilities to the user are provided by the MCS system. In some of the Converged Desktop scenarios calls can route through the MCS before terminating to a Centrex line. To preserve the Public/Private name and number in the call this feature will add additional field to provision the CD Preferred Audio Device (PAD) for incoming private calls. The existing field used to provision the PAD number will default for accessing the PAD when incoming Public calls are received.

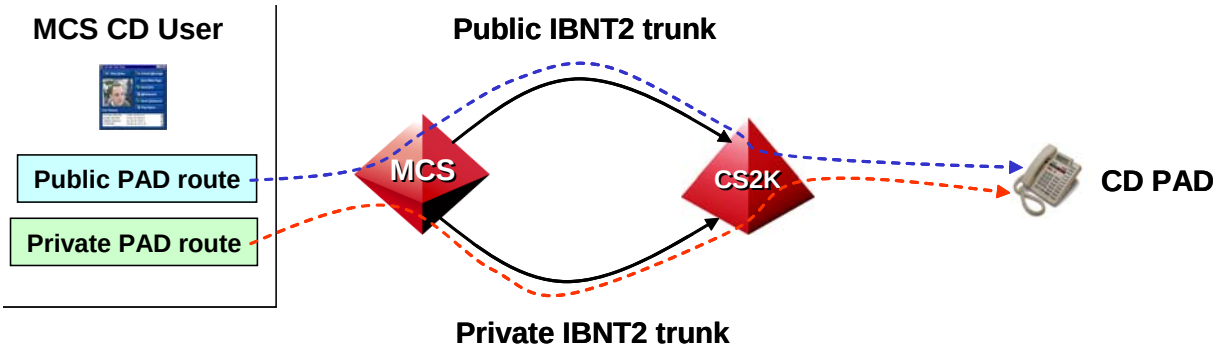


Figure 5 Converged Desktop PAD's public and private routes

The rules for selecting the public or private PAD number provisioned at the MCS are as follows:

Table 1 Rules for using the Private or Public number

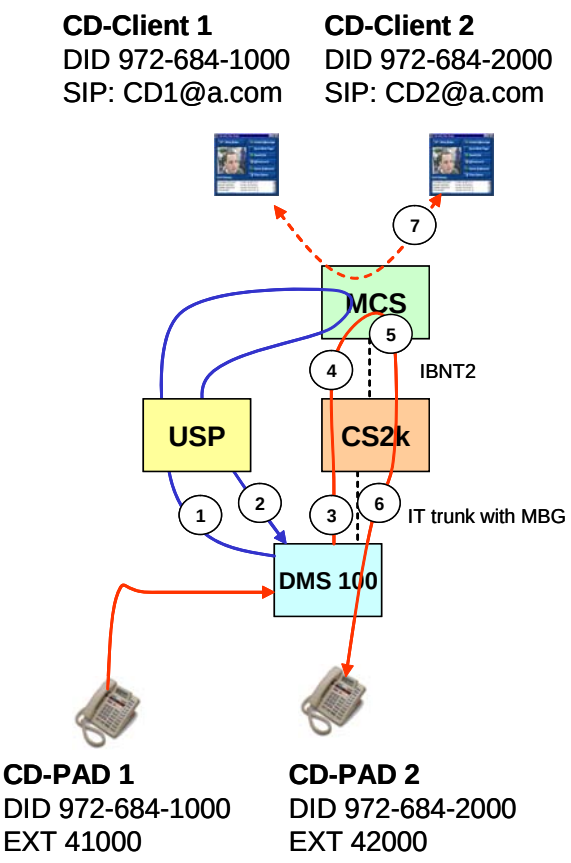
Private PAD Number is used when
1. Originator and terminator are in the same root domain. Originator could be another PC Client or a CD2 user. 2. Originator and terminator are in different domains, but the public name or number for the originator is NOT provisioned. 3. Public PAD number is not provisioned.
Public PAD number used when
1. Originator and terminator are in different domains and the originator has a public name or number provisioned. 2. Incoming subscriber is not known at the MCS. 3. Private PAD number is not provisioned.

The next diagram shows a complex CD call where call traverses the MCS before terminating to a CD PAD. The sample is based on Centrex groups located on a DMS switch instead of the CS2k and MBG protocol is used between the CS2k and DMS to route Private name and number. After Terminating Attempt Trigger response is complete the CS2K routes the call MCS over IBNT2 trunk using the CD Service Provisioned on the MCS. The CS2K marks this call as private because MBG was involved between the CS2k and DMS switch. In Step 5 since the incoming call was marked private the MCS selects the “Private” PAD number assigned to the terminator to perform translations and route lookup. The “Private” PAD number should be provisioned so that a private Gateway route is used to terminate back to the CS2k (step 5) for incoming private calls. The same private route will be used if a PC Client that is in the sub-domain calls this CD user. Similarly, a public PAD number should be provisioned to route incoming public calls.

Normally, when a Converged Client makes a call from the PC Client the first leg of the call will always take the Private GW route because the originator’s CD client and the originator’s PAD are provisioned to use the same domain. After the originator answers its PAD and the terminating call will be determined where if the terminator is located in the same domain as the originator.

If a private PAD number is not provisioned the public route will always be used.

Restriction/Limitation: the MCS CD clients will display the calling/called numbers provided by the CS2k. No reverse translations are performed at the MCS for number display.



1. TAT Trigger
   Calling Number: 972-684-1000
   Called Number: 972-684-2000

Figure 6 Converged Desktop Complex call

110.4.4 Interactions with Call Forward

Call forward scenarios include calls that are received from a PC Client or incoming from a Gateway that get routed to other domains or Gateways. The following figure shows the various scenarios and behavior of the private/ public name and number display.

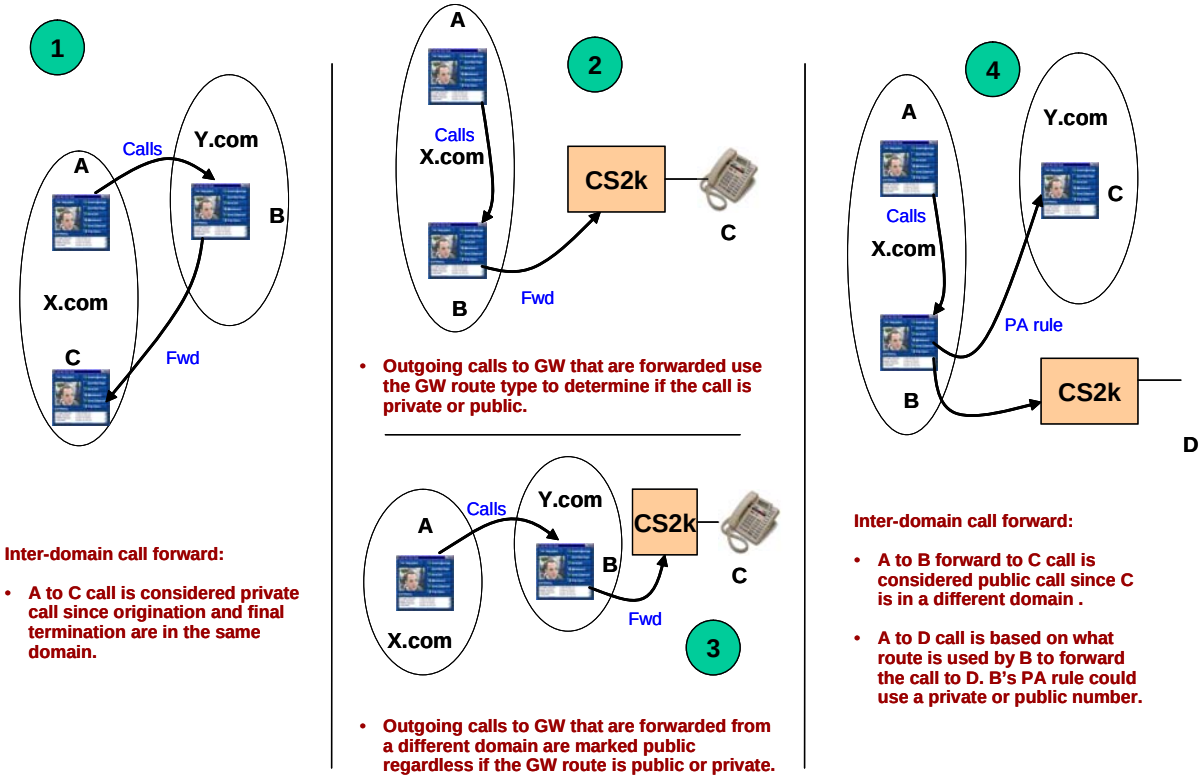

Figure 7 Call forward scenarios

Basically if the originator and terminator are in the same root domain then the call is considered private. The same rules will apply when A is transferred between domains and Gateways.

Public Name and Number is also applied to intermediate parties that involved in the redirection. For example, in scenario number 3 if domain Y.com has public name/number provisioned, and the Gateway route to C is marked "Public". When party B forwards the call to party C using the Gateway the redirecting headers are updated with party B's public name and number.

110.4.5 Interactions with Call Transfer

Call Transfer using SIP is implemented a little different than the traditional PSTN networks. In SIP networks when two parties are connected (A connected to B) and one party (B) transfers the call to another party (C), the party transferring the call (B) sends the request to the connected (A) and then the connected party sets up a new call to the target (C). The transferring party (B) is notified when the transfer is complete and releases the original connected call (call between A and B). The difference between SIP and traditional PSTN network transfer is that in PSTN networks the transfer

request is not sent to the originator of the call, but the PSTN switch handles the request.

The difference requires that the party transferring the call be hidden if the transferring party has public name and number provisioned. It also requires that the new target be hidden and presented with originator's public name/ number. The following figure shows how the call transfer with PPND works:

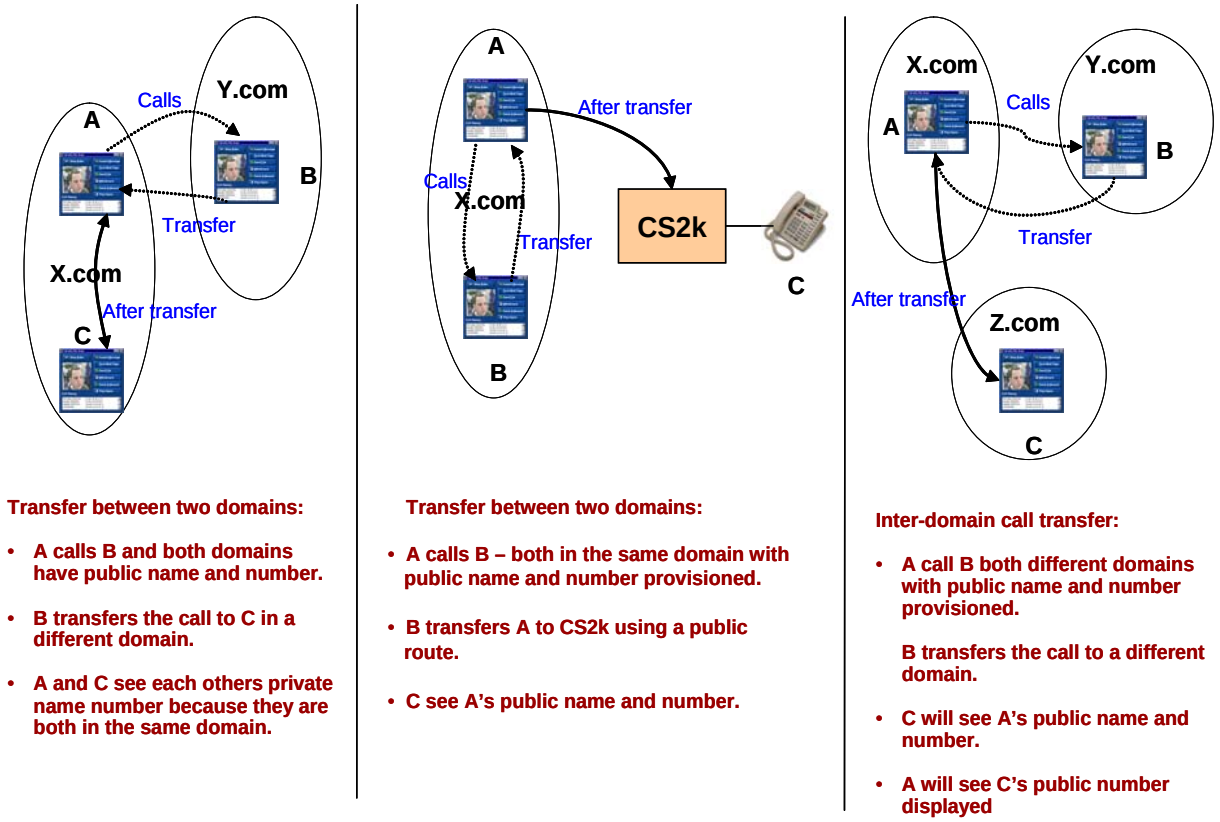

Figure 8 Call transfer scenarios

The call transfer service is also the underlining service used by the MCS Call Park and Boss Admin service. If calls are parked and retrieved in a different domain, the originating party will see the public number of the party that retrieved the call. *Note: Call Park and Boss Admin service can only be used in a single domain and cannot span multiple domains – i.e. cannot park a call in one root domain and retrieve it in another root domain.*

The public name and number rules are summarized here when a call transfer occurs:

1. The originator (A is the figure above) sees the connected public number of the terminator (C in figure above) if it is provisioned. If only the public *name* is provisioned at the domain level then the private user ID or number is displayed on the originator (A).
2. The target (C in the figure above) sees the public name/number of the originator if the two are in different domains.

110.4.6 Interactions with Foreign domains

Foreign domain incoming or outgoing calls are considered PUBLIC and it is up to the foreign domain to control what name or number is sent in the request to the next proxy.

Call forward and call transfer that occur in the foreign domain could provide the public name and number, but it all depends on how the foreign domain proxy handles the call forward and transfer requests. Some systems can handle the call redirections, and other systems might send the request back to the originating system to handle the call redirections. If the requests are sent back to the originating system for call redirection then the originating system can re-apply its public name and number rules. If the foreign system handles the call redirection then the foreign domain's public name and number rules will apply to any redirection.

If the foreign domain system is an MCS system and the terminating subscriber in the foreign domain transfers the call. The transfer request is sent back to the originator on the different system. The originator re-applies the public name and number rules before calling the target. For example, A and B are in foreign domains on different systems and B transfers the call to C who happens to be in the same system/domain as A. A will apply public name number rules when connecting to party C and deliver A's private name and number. If C happens to be in a foreign domain on different system, A's public name and number will be delivered to C.

110.4.7 E911 Interactions

The public/private name display service does not run if the E911 call in involved.

110.4.8 Interactions with Privacy

This feature will look for privacy tags for name and number. If privacy is enabled for calling name and number then public/private name and numbers will not be populated. For calls with partial privacy where number might be allowed, but not name only the public/private number rules used by this feature will be applied.

110.4.9 Interactions with Meet-me

If the public name/number are provisioned for a domain, a call to a meet-me bridge in a different domain will result in call being public.

110.4.10 Network Call logs

Network call logs available for both incoming and outgoing calls for an MCS subscriber. If the domain name/number is provisioned for the originating domain the terminating user in a different domain will have the originator's public name/number in the call logs. The originator's outbox call logs will have dialed digits if the terminating domain has public name provisioned and is different than the originating domain.

110.5 SIP Telephony route

The MCS RE-IP feature changed the way SIP routes can now be defined with the MCS. There are now two ways a SIP telephony route can be defined:

1. **Alias Lookup** – this type of sip route performs an alias lookup of the incoming digits in the domain provisioned in the sip route. If the subscriber is found with the alias the call terminates. Otherwise, based on the route option (continue, stop, etc) the call continue on to Gateway translations or gets rejected.
2. **Inter-domain** – this type of sip route forwards the request to the new domain specified in the sip route. The domain specified in the sip performs that required translations based on the incoming request. The sip route can modify the number before forwarding the request to the other domain for translations. This route is similar to how Gateways can be setup to route call to another domains on the same MCS system – sometimes referred to as "fake" gateway routes.

110.6 Inter-domain blocked calls

Inter-domain routing restriction is a new capability added by this feature to block **"direct SIP calls**" between two different SIP domains hosted by the MCS system. "Direct sip calls" refer to a subscriber dialing a number or a sip user ID from one domain to another domain by specifying the other domain in the request. For example, a user in domain A.com dials a user in B.com by using userB@B.com. The domains have to be **root domains** and not sub-domains hosted by the ***same*** MCS system. Today in some of the carrier deployments if a user dials a user in another domain using digits, the call routes over to the CS2K before returning back to the MCS for termination. This allows the carrier to reuse some of services currently not available on MCS (.e.g. PICS for carrier selection, SMDR billing, etc). If domain "A" blocks direct SIP calls to domain "B" then the following MCS services are blocked as well:

- Instant Messages
- Presence – sending presence of a user to the banned domain. This can be confusing, but presence banning is opposite of making calls. For example, if A.com adds provisioning to ban all service to B.com. All calls to B.com from A.com are banned and users from B.com cannot watch users in

A.com. Users in A.com can still watch users in B.com unless B.com adds a banned list for A.com.

- Collaborations
- Web Co-Browsing
- Send File
- Direct call forwarding and call transfers to restricted domains

A domain that restricts direct SIP calls to another domain is applied to making calls using Telephony routes as well. These telephony routes can be SIP routes to other domains that either perform an Alias lookup or perform inter-domain routing in the other domain. Inter-domain calls terminating to a Converged Desktop are not restricted. Refer to the next section for more information on this restriction.

Blocked calls are rejected by a SIP 403 forbidden response.

There are two ways to provision blocking in the “Banned” user list menu. Either the complete root level domain is banned (.e.g. *@domain.com) or a single user ID is blocked (e.g. 2146841038@domain.com).

110.6.1 Inter-domain blocked call restrictions

This feature would allow an administrator to block “direct” inter-domain calls using user’s aliases or SIP User ID. This restriction will apply to CD subscribers that use the PC Client to dial another subscriber in a different domain using an Alias or SIP User ID. If the restriction between domains is set then call will not complete and is rejected by a SIP 403.

Inter-domain restriction will NOT apply if the terminator is a CD2 user and in a different domain than the originator of the call. This is to prevent calls from getting denied when a CD2 users in one domain using a PAD calls another CD2 users on a different domain. In this scenario call could loop through the MCS and get denied because the originator is in a different domain than the terminator even though both users a using PSTN phones.

The following table provides the various scenarios when calls are blocked with inter-domain restriction:

	Originator type (A.com)	Terminating type (B.com)	Termination blocked
1.	SIP	SIP	Yes
2.	SIP (e.g. 444@B.com)	Gateway Route	Yes
3.	SIP	Foreign domain	Yes
4.	SIP	SIP PA forwarded back to A.com	Yes

5.	Gateway route	Gateway route	Yes
6.	Gateway route	SIP	Yes
7.	Gateway route	Foreign domain	Yes
8.	Gateway route	SIP PA forwarded back to A.com	Yes
9.	SIP	CD2 User	***No***
10.	CD2 User	CD2 User	***No***
11.	CD2 User	SIP	Yes
12.	CD2 User	Gateway Route	Yes
13.	CD2 User	Foreign domain	Yes
14.	SIP	CD2 User PA forwarded to SIP user in B.com	**No**
15.	SIP	CD2 User PA forwarded to Gateway route A.com	Yes
16.	SIP	CD2 User PA forwarded to a Foreign domain in B.com	Yes
17.	SIP	CD2 User PA forwarded to a SIP user in domain A.com	Yes
18.	Gateway route	CD2 User PA forwarded to SIP user in B.com	**No**
19.	Gateway route	CD2 User PA forwarded to Gateway route B.com	**No**
20.	Gateway route	CD2 User PA forwarded to a Foreign domain in B.com	Yes
21.	Gateway route	CD2 User PA forwarded to a SIP user in domain A.com	Yes

The table assumes that A.com is blocking calls to B.com and B.com is blocking calls to A.com.

Inter-domain restrictions WILL apply to CD2 users other features if the incoming call is from a domain that is blocked from calling CD2 user's domain:

1. If Branding is assigned to the CD2.
2. If Music on Hold is assigned.

Domain restrictions should only be provisioned between root level domains and NOT for sub-domains. For example, if *@a.com is provisioned as a banned user in b.com then any requests from b.com to a.com are blocked. If a.com has a sub-domain sub.a.com and this is provisioned at b.com then blocking will NOT work. Inter-domain restriction only works at the root level domains.

110.6.2 Network configurations

For private name and number to work between the MCS and CS2k it is required that the CS2k trunk type to the MCS be set as IBNT2. The following diagram shows a mapping of Private/Public calls between a Sub-domain on the MCS and a Centrex group on the CS2K.

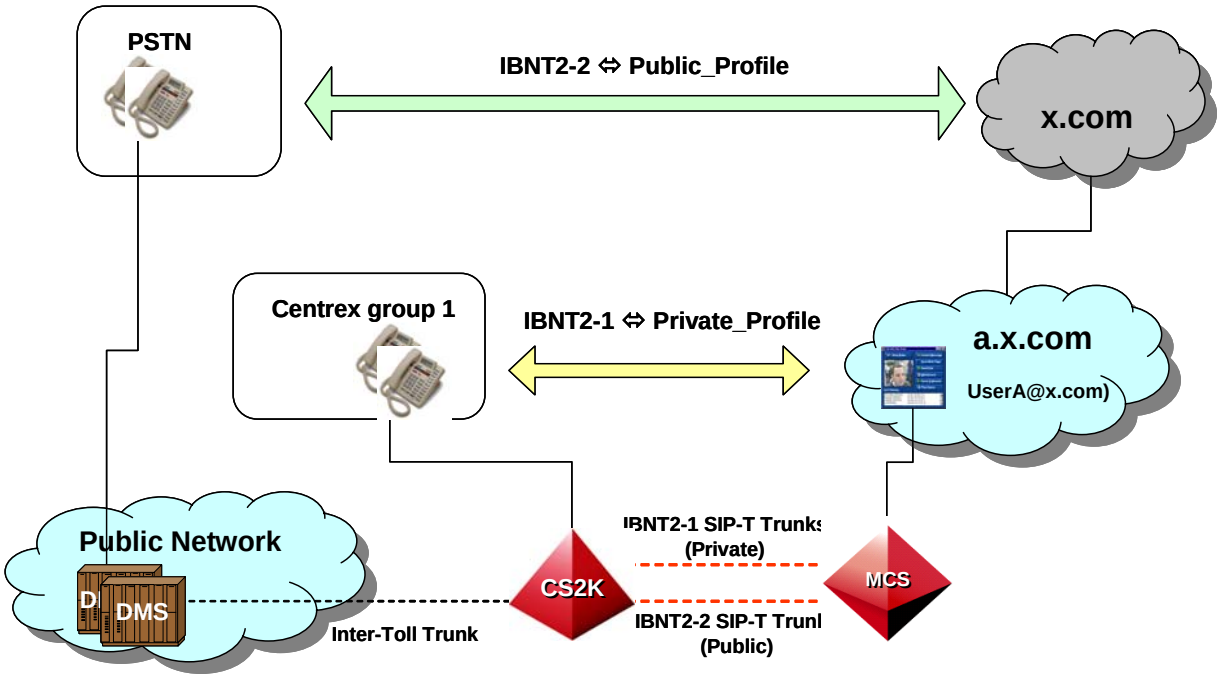

Figure 9 Centrx group profile mapping to MCS domain

A “Profile” header is used between the MCS and CS2K to determine what translations need to be handled on each node. On the MCS a “Profile” maps to a domain or sub-domain. On the CS2k the “Profile” header maps to a set of IBNT2 trunk types. In the diagram above a “Private” Profile is defined between the CS2k Centrex group and MCS sub-domain “a.x.com”. Any private calls that originate from the CS2k could map to the MCS sub-domain that is an extension of the Centrex group. The sub-domain’s translations are run because of the “Profile” header mapping and terminate to the users within the sub-domain. For outgoing calls to the Centrex group from the MCS the sub-domain’s translation can be setup to route add the “Private” profile, private name and number.

Users in the sub-domain “a.x.com” can be setup to route “Public” calls to the Public TDM network using a different set of translations that delivers the public name and number. In the diagram above the “Public” translations for the sub-domain are defined in the parent domain. During MCS translations if a number range does not match in the sub-domain the parent domain is searched

for match. In this case the parent domain has a Profile that maps to an IBNT2 trunk on the CS2k for handling public calls to the TDM network. The parent domain can be setup to route the call to TDM using the “Public” name and number of the sub-domain when a user from “a.x.com” makes a call.

The following diagram shows an example on how a Centrex group could be extended between the MCS and other TDM switches. If IBNT2 trunks are provisioned for private calls the private call indication can be passed to other TDM switches using the concept of Multi-Location Business Groups (MBG) over Inter-Toll trunks (IT).

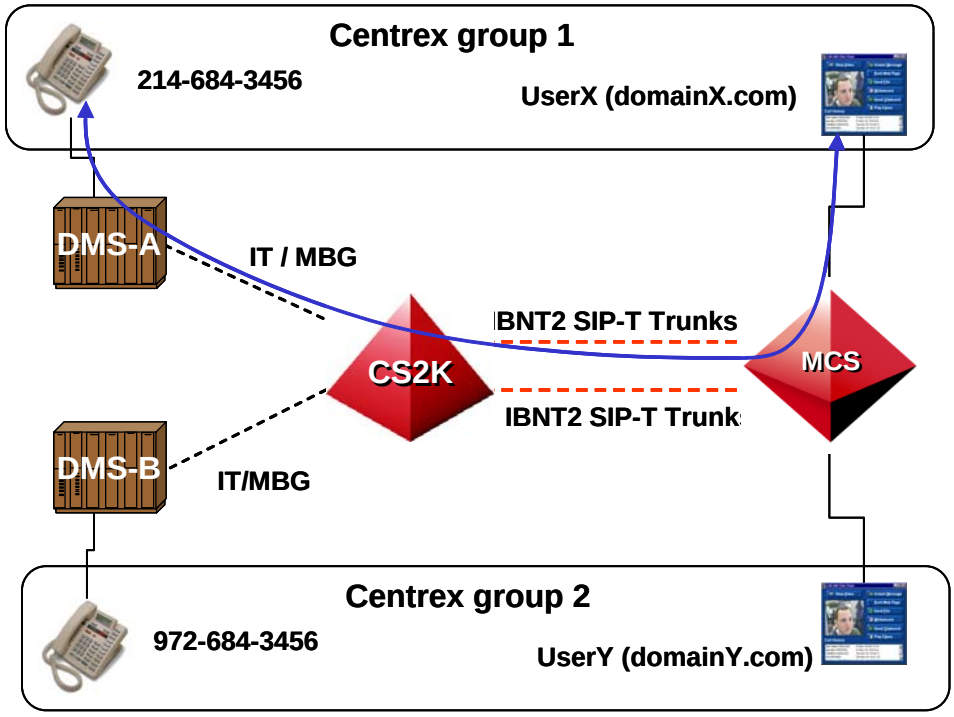

Figure 10 Centrex group and MCS domain example

The Centrex group transparency for “Private” name and number between Centrex group users on a DMS and MCS is provided by MBG. The CS2K in the middle maps the private name/number from the IBNT2 trunk to the Inter-Toll trunks using the MBG parameters.

110.7 Configuration changes/additions

110.7.1 Provisioning Client / Database additions

New parameters will be added to the database that can only be provisioned by the operator with system admin level privilege. These parameters are:

- Public name and number fields for domain and sub-domains.
- Sip telephony routes to define public and private routes.

Upgrade scripts will have to be written to take into account these new fields when upgrading the database from an existing release to a new release that supports this feature.

110.7.2 Configuring Public Name and Number

Two new fields called Public Name and Public Number will be added in the domain parameters section of the domain and also in the sub-domain.

- By default both of these fields will be empty when a new domain is created.
- A sub-domain (if created) can have its own unique Public Name and Public Number fields.
- For both domain and sub-domain the system administrator needs to data-fill the two sub-domain fields with a valid name and a valid number.
- For both domain and sub-domain, the system will not perform any checks to determine if the public number data-filled is route able or not.

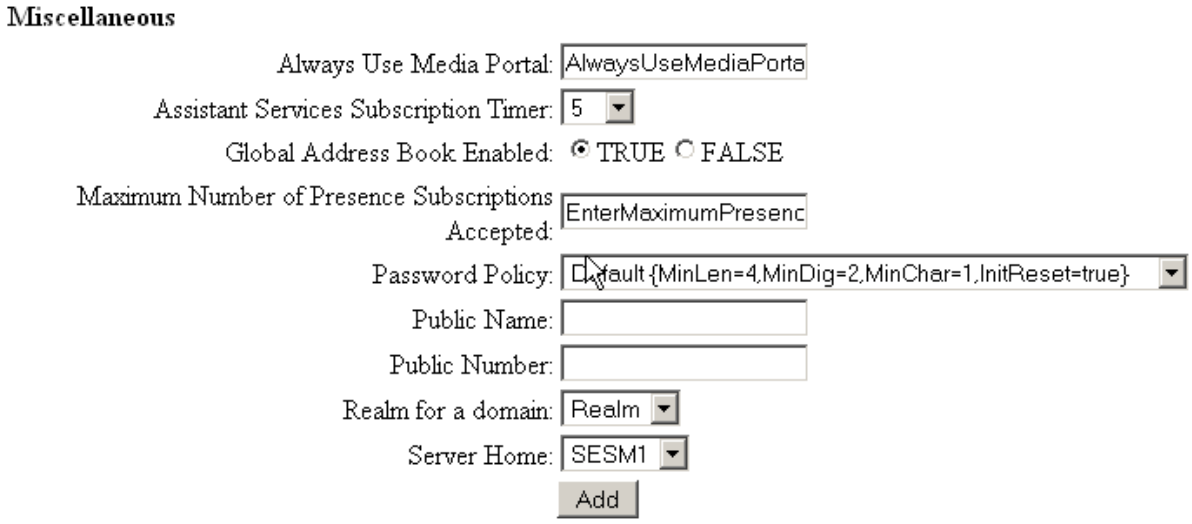

Figure 11 Domain parameter

Note: provisioning these fields basically triggers this feature to deliver public or private name/number. Without provisioning a public name against a domain the private name is delivered based on the call scenario. If a public number is not provisioned either against a domain the private number or SIP user ID is delivered based on the call scenario.

110.7.3 Configuring Restricted Domains

Existing Banned User menu (for a domain) will be utilized to restrict *name dialing* between two domains that have been defined in the MCS system.

- A user put in banned list will not be able to make any calls, IMs, or Collaboration outside his/her domain.
- Admin operator can put a restriction at a domain level to disallow all users making any calls, IMs, or Collaboration, outside their domain.

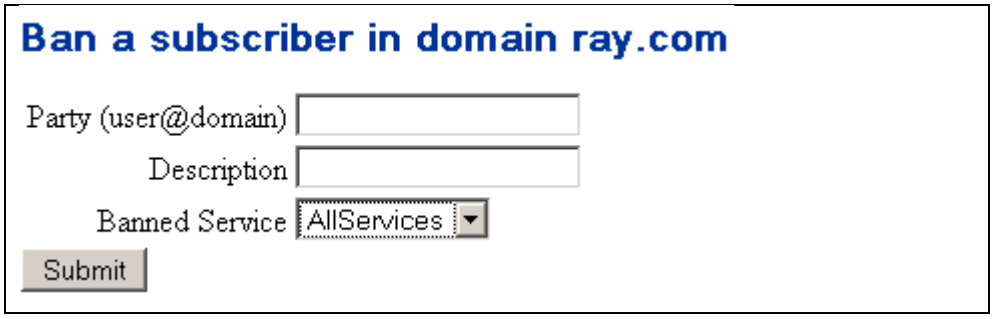

Figure 12 Restricted domains menu

There are two ways to provision blocking in the “Banned” user list menu. Either the complete root level domain is banned (.e.g. *@domain.com) or a single user ID is blocked (e.g. 2146841038@domain.com).

110.7.4 Configuring Gateway routes

A new provisioning field is available with Gateway routes. A new field called Override Public Name will be added for both SIP and gateway route to override the domain’s public name.

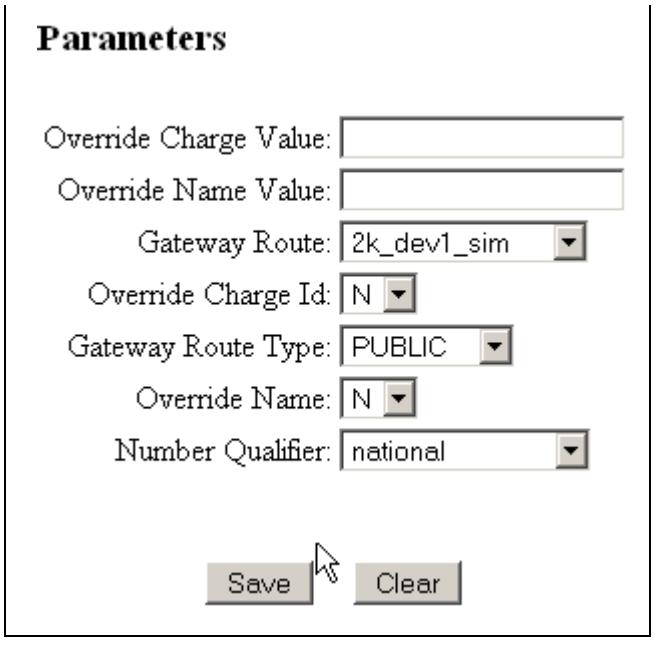

Figure 13 SIP/Gateway Telephony route parameters

110.7.5 Configuring SIP Telephony Routes

SIP Routes have a new option “Inter-Domain Routing” that allows the use of Telephony routing to lookup subscriber and other Telephony routes in other domains. If “Inter-Domain Alias Lookup” route type is selected then the telephony route lookups the subscriber alias in the other domain.

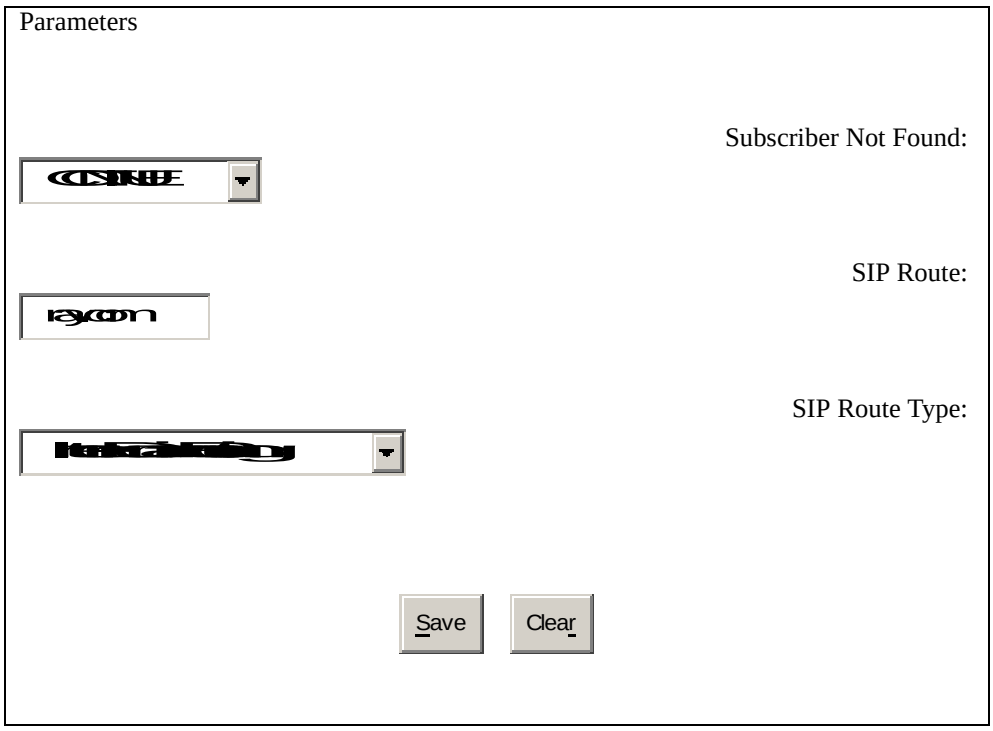

Figure 14 SIP/Gateway Telephony route parameters

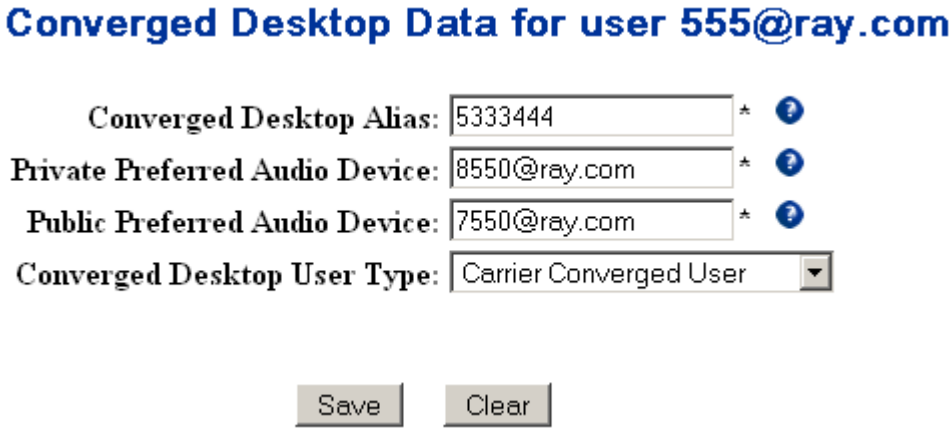
110.8 Converged Desktop PAD provisioning

An additional field is added by this feature to provision digits that would allow “Public” call to be reached to Converged Desktop users PAD.

Figure 15 Private and Public PAD provisoning



110.9 Software Requirements or Dependencies

This feature is part of the MCS09 release and dependant on some of the function introduced by feature – A00009419 Out Of Band Refer for Converged Desktop 2. ***Out of Band Refer is only available to native lines on the CS2k and this Refer is NOT propagated to other CS2k or DMS switches.***

To determine the Public/Private nature of the call the PSTN Gateways like CS2k, and PRI Gateways need to provide Phone-Context indication. The use of Phone-Context is described in the MCS inter-working specifications and in IEFT RFC2806.

110.10 Limitations and restrictions

The following restrictions and limitations are applied by this feature:

- The MCS CD clients will display the calling/called numbers provided by the CS2k. No reverse translations are performed at the MCS for number display.
- IBNT2 Trunk Type is required between the CS2k and MCS to support Private Name/Number display.
- Inter-domain blocking does not apply to Converged Desktop users.
- Public/private name and number display is not applied on the MCS Presence service.

110.11 Interactions

This feature inter-acts with the following MCS server features and these are described in the previous sections for this document:

1. Converged Desktop
2. Call Forward
3. Call Transfer
4. Privacy Server
5. Network Call logs
6. E911
7. Meet-me

110.12 Glossary

PRI	Primary Rate Interface
TDM	Time Division Multiplexing

111: Functional Description(FN): A00009950

A00009950 (CICM) & A00010293 (GWC) - Media Portal Removal for Inactive CICM Clients

111.1 Description

Calls terminating to CICM lines are allowed to complete even if the user associated with the DN is not logged into a CICM client at the time of the call. This behavior is required to allow feature interactions such as call forwarding and voice mail to function correctly when the terminating CICM user is not logged in. Additionally, the user in question can log into a CICM client whilst being called and receive alerting and answer the call.

Prior to this SN09 feature, this behavior has been achieved by inserting a Media Portal for calls terminating to a logged out CICM user. This provides the originating endpoint with a real network location to send its pre-answer audio stream to, and automatically discovers the media address of a terminal that logs in and starts transmitting its audio stream. This allows a two-way speech path to be achieved if the user logs in and answers the call.

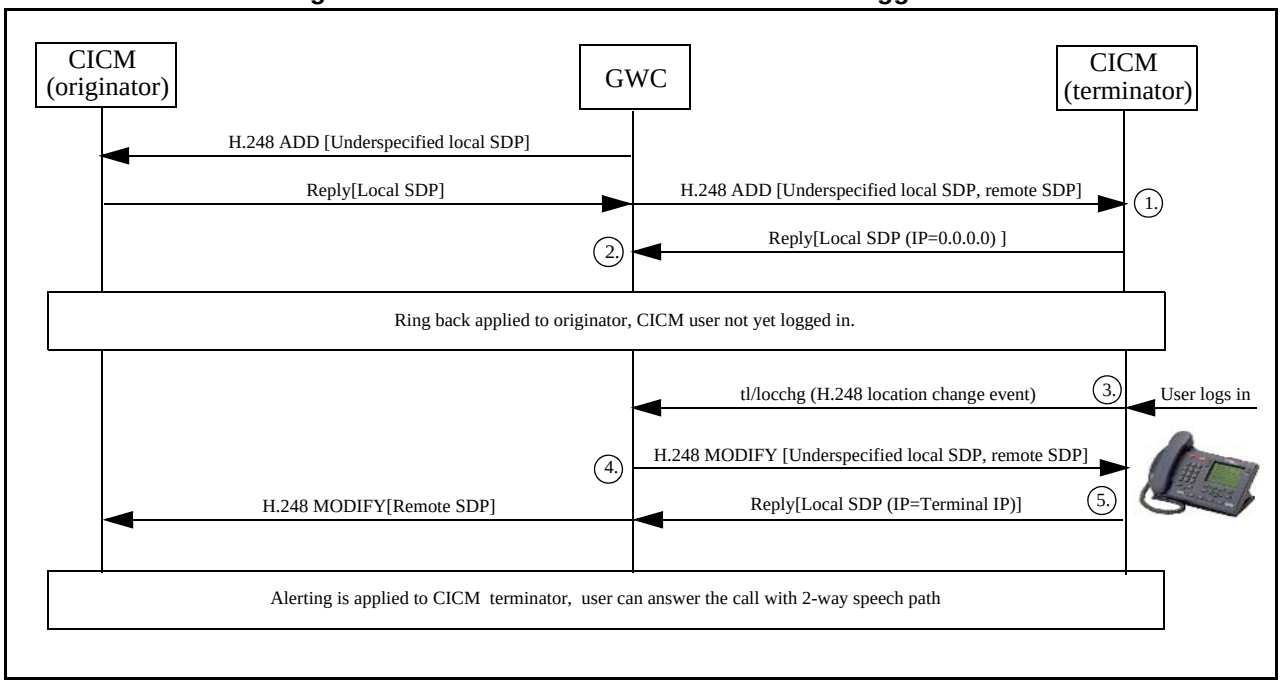
The previous architecture leads to the requirement that Media Portals must be deployed in all CICM networks, even if the NAT traversal capabilities usually associated with Media Portals are not required (ie in a flat network solution). This CICM 9.0 activity will removes this requirement and allows such feature interactions to function correctly without the use of a Media Portal. This is a cost reducing effort for customers who have networks that do not require NAT traversal.

111.1.1 GWC-CICM message flow

For a call terminating to a CICM client in a flat network, the CICM sends the originating endpoint (via the cs2k) a Session Description Protocol (SDP) message, which contains the media address of the CICM client to which the originator will direct is audio stream. This happens at call setup time (pre-answer), so if the terminating CICM user is not logged in then the media address of the CICM client is not known, therefore the Media Portal is required to provided a sink for the pre-answer audio stream.

This feature removes the requirement for the Media Portal by delaying the terminating CICM users Session Description Protocol (SDP) until the CICM user logs in, at which point the media address of the CICM client is known.

Figure 1 - CICM to CICM call - terminator is logged out



1.) Terminating CICM receives a H.248 ADD with the underspecified local and remote SDPs. The CICM user is not logged in, therefore the IP address of the terminating client is not available, so the CICM responds with a local SDP with a dummy IP address.

2.) The GWC does not pass the SDP onto the originating CICM, but simply ignores it.

3.) Terminating user logs in. The CICM raises the H.248 location change event to the GWC.

4.) The GWC responds with a H.248 MODIFY with underspecified local and remote SDP.

5.) Terminating CICM responds with the updated local SDP, containing the IP address of the terminating CICM client.

111.2 Hardware Requirements or Dependencies

This activity does not introduce any new hardware requirements or dependencies.

111.3 Software Requirements or Dependencies

This activity does not introduce any new software requirements or dependencies.

SDP	Session Description Protocol

112: Functional Description(FN): A00009951

A00009951: Introduction of 221X Wireless handset

112.1 Overview

This feature introduces CICM support for the IP Phones 2210, 2211 and 2212. These are 802.11b compliant VoIP wireless handsets, the IP Phone 2210 is the cost effective low end model and IP Phone 2211 is the high end model with more advanced features. The IP Phone 2212 is visually similar to 2210, but with backlit keypad and display, push to talk, and a more robust design.

2210 is a lightweight, durable handset which is more suitable for a typical office environment whereas IP Phone 2211 is bulky and is engineered for a robust kind of environment. The IP Phone 2212 is essentially a combination of the other two phones in the form factor of the 2210, and therefore is ideally suited for either the office or a more robust environment.

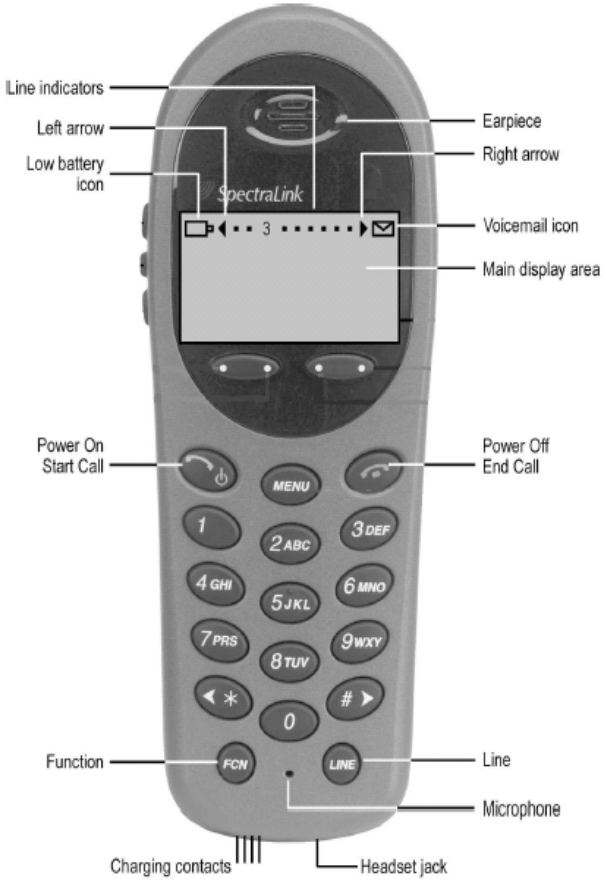

Figure 1 IP Phone 2210 handset

Figure 2 IP Phone 2211 handset

The IP Phone 2210/2211/2212 emulates an IP Phone 2004.

The features of these handsets are:

- The IP Phone 2210 is a cost effective low end model and the IP Phone 2211 and 2212 are the high end models with advanced features. All of them are 802.11b compliant.
- They support the UNIStim signaling protocol.
- The IP Phone 2211 handset has a “Push to Talk “feature.

- The IP Phone 2212 handset has the compact form factor of the 2210, but the Push To Talk and robustness functionality of the IP Phone 2211

112.2 Comparison of IP Phone 221X over IP Phone 2004

The IP Phone 221x emulates an IP Phone 2004. The IP Phone 221x has fewer buttons and a smaller display. Following are the features supported by IP Phone 221x and differences when compared with IP Phone 2004:

112.2.1 Standby/Active On-Hook state

The idle state of the handset is Standby state. The handset is still in communication with the CICM in this mode. In this mode, the handset does not communicate button pushes to the CICM and hence no features can be activated. The phone's display is also inactive

The Handset needs to be brought into active state to perform any actions. The handset can enter active On-Hook state by pressing the key sequence ON+FCN+3 or by pressing the Power On (green) key. In this mode the user can access the CICM functionalities. The phone's display is active and displays a message "EXT----- "and the phone's display is active and the phone rings loudly (i.e. NOT in-ear ringing).

The user exits the active On-Hook state and returns to standby state by pressing the END key. The phone returns to the standby state if no key is pressed for a period of 10 seconds which is the timeout for the active On-Hook state.

When the phone is in active On-Hook state, the user has access to various menus (MENU, FCN, or LINE).The phone remains in an active state when any menu is selected or a soft key is pressed, phone performs in-ear ringing and does not return to standby state. Menu can be exited by pressing the END key. Pressing the END key again returns the phone to standby mode.

The Predial feature is present in IP Phone 221x.

112.2.2 Hands Free State

The Set does not have any hands free capability and hence any feature requiring the hands-free is not supported. For example when there is an incoming call to the IP Phone 2004 which is in idle state but off-hook, the set will buzz the hands free speaker. This feature is not supported on IP Phone 221x.

112.2.3 Available Keys

The IP Phone 221X does not support all the buttons present on IP Phone 2004 and the operations on those keys are not supported.

The keys which are not available on IP Phone 221x are:

- Globe Key
- Expand to PC key
- Navigation (Left, Right, Up, Down) Keys
- Stop Key
- Copy Key
- Headset Key
- Hands free Key

112.2.4 Navigational keys

IP Phone 221x does not have navigational keys. Navigation of menus is provided by two soft keys (refer to figure 3). These soft keys scroll through the menu options in the same way as the up down keys of IP Phone 2004. IP Phone 221x does not have the Navigational up down arrows. See Figure 3.

Figure 3 Navigation using soft key

IP Phone 221x supports directional keys. They provide the directional keys only inside the terminal specified menus, viz "*"and "#" keys act as Left/Right keys (refer to figure 4) and the "volume keys" positioned on the left side of the handset behave as UP/DOWN (refer to figure 5).

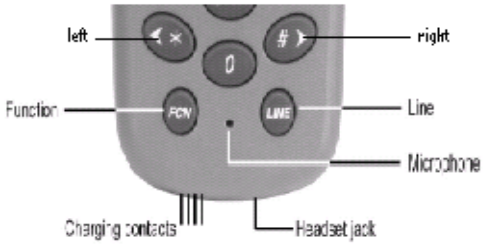

Figure 4 - Left/Right Keys

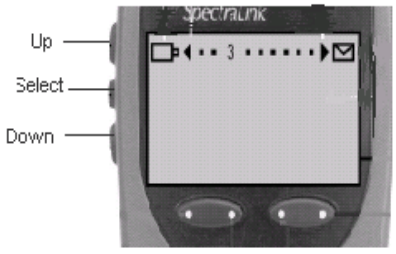

Figure 5- Up/DownKeys

112.2.5 Display

The set display is divided into 3 main areas:

- The top area is a status row which displays the status icons of each line appearance, a message waiting indicator which is an envelope icon, a battery level indicator, and left and right arrows.
- Below that is a text area that is 4 lines by 19 characters when compared to 24 characters of IP Phone 2004. Lines in 4 x 19 text area which are longer than 19 characters are truncated by special algorithm that removes spaces and punctuation first, then vowels, etc., right to left.
- Below that is a row of soft labels. A soft label is a maximum of 4 characters long. The soft labels are compressed with the same algorithm as used in the text area. The soft labels support soft key layers and cadences so that the flashing icon associated with some features, e.g. conference, are supported.

In Figure 5 the top area shows the status icon and a message waiting indicator. This area of display is also used to display the feature key selected. The number 3 in the above figure represents that the key 3 is selected.

The contrast levels of the terminal via CICM cannot be adjusted. The menu option for contrast level adjustment is blocked.

The time and date display fields are not available as the 221x terminals don't support them. Refer to figure 6. The menu option for setting the time and date format is blocked.

The menu options which are available on i221x terminals are shown in figure 8.

The 221x terminals do not support extended ASCII characters. 221x terminals use an asterisk sign (" * ") to represent a default selected item instead of tick mark when compared to 200x terminals. Refer to figure 7.

The handsets support all languages.

Figure 7

112.2.6 Soft Labels:

The soft labels on IP Phone 221x are 4 characters in width when compared to 7 characters on IP Phone 2004. Although the number of characters is 4, the menu button has a list of complete words available for the features.

112.2.7 Soft Keys:

The terminals have four soft keys (two rocker switches) directly below the display**.** The soft keys are not available when the handset is in the standby state. The character strings displayed on screen is the result of compression mechanism which removes vowels and spaces. A range of specific strings are created to make the screen legible, changes are only made to the menu options and not to the user defined feature keys.

112.2.8 Feature Keys

IP Phone 2004 has 14 feature keys when compared to IP Phone 221x which has only 6 feature keys.

These feature keys can be accessed by pressing the LINE key. A user can have 14 features data filled against the line; however he will be able to activate the first six features only if he logs into the CICM using an IP Phone 221x.

The figure below shows the menu which is available on a 221x terminal.

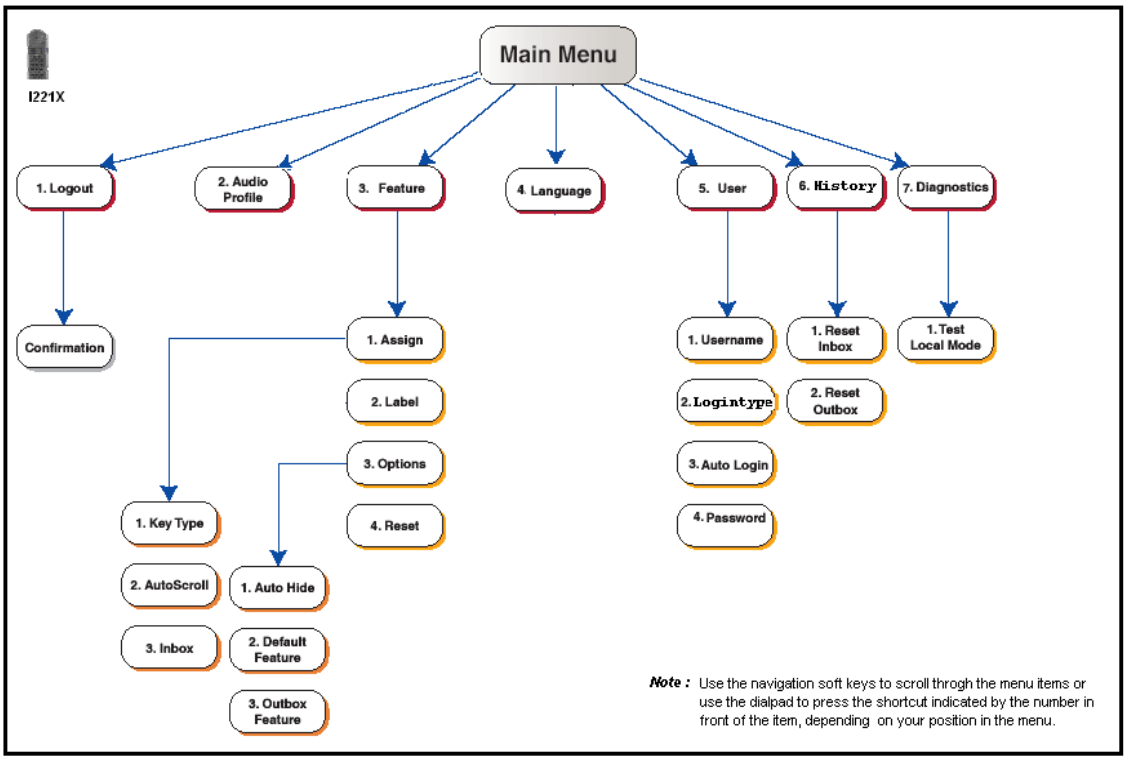

Figure 8

112.2.9 Tones

The 221x terminal doesn't currently support the stream based tones due to a firmware limitation. Therefore, until an updated firmware is available, the tones are not able to be tailored to specific markets and the current set of tones do not accurately match those of the North American Market. This is expected to be a short term workaround but please check on the delivery timeframe prior to committing to any deployment.

112.2.10 Message waiting and Missed Call indicator

An Envelope icon is displayed to indicate the Missed calls but along with the envelope icon the user is presented with the display of text messages to indicate if there is any missed call also to indicate if there is any message waiting. Please refer to figure 9 and figure 10.

Figure 9

Figure 10

112.2.11 Handset User Interface

The handset is a close adaptation of IP Phone 2004 user interface. The following keys of IP Phone 2004 are mapped into the IP Phone 221x handsets.

- Soft keys: These are directly mapped to handset soft keys with display in compressed format. Also menu list is mapped under the MENU key with display in an uncompressed format
- Feature / DN keys: Mapped to the menu list under the LINE key. To access feature keys located to left and right of the main display, press the LINE key and then select the required key from the list.
- Hold, Goodbye, Directory, Inbox, Mute and Outbox: These are mapped to the menu list under the FUNCTION key. To access these keys press FUNCTION key and select the relevant key from the list. On pressing the Mute key the message Mute is displayed as shown in figure 11.

The below figure shows the mapping of keys of IP Phone 2004 to IP Phone 221x wireless handsets:

Fig 12 IP Phone 2004

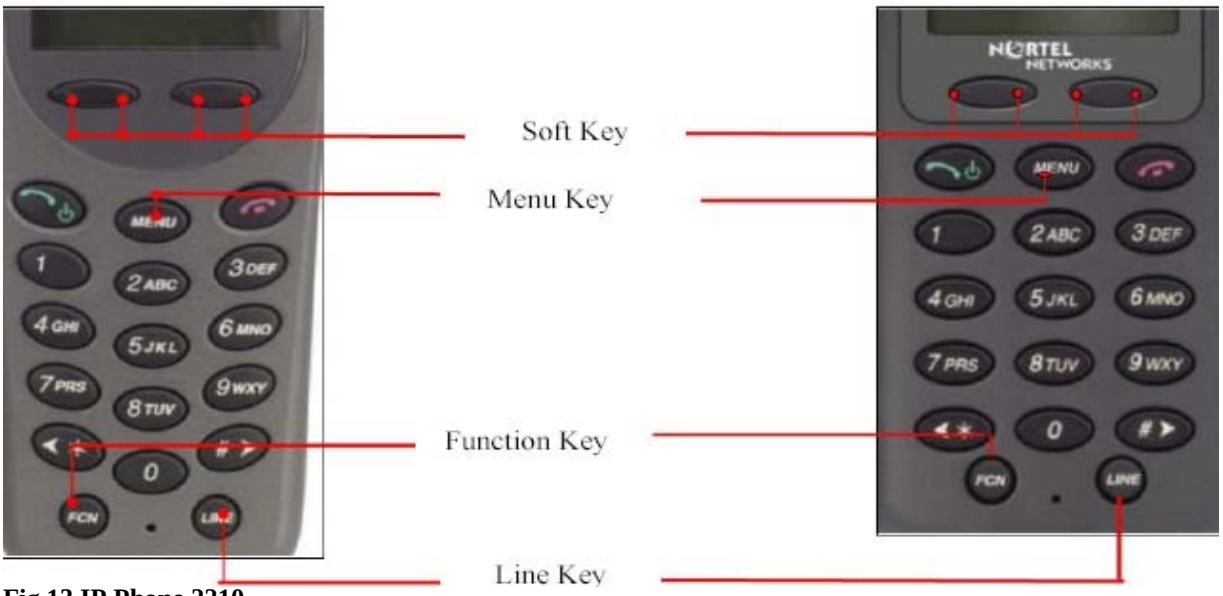

Fig 13 IP Phone 2210

Fig 13 IP Phone 2211

112.2.12 Disconnecting

When a call to IP Phone 221x is terminated by the far end and the 2210/11 user does not press the END key the phone continues to stay in the active state even though the call has been terminated i.e. it can receive another call. In the active state, the IP Phone 221x exchanges messages with the 2245 server (refer section 2.6) every 30 msec. This consumes RF bandwidth and reduces battery life.

112.2.13 QoS

End to end QoS, i.e. DiffServ, is not supported.

Layer 2 QoS, i.e. 802.1 p/q is not supported.

Quality of Service is provided by the 2245 (refer section 2.6) using the Spectra Link Voice Priority (SVP) protocol.

112.2.14 Codecs

Both G.711 and G.729 A/B codecs are supported. The RTP packets which transit between the IP Phone 221x and the 2245 server always contain 30 msecs of voice. The 2245 server repackages the voice data to the correct packet size. The jitter buffer is always configured to 70 msecs.

112.2.15 RTCP

RTCP is not supported. Incoming RTCP packets are discarded. On a query for RTCP parameters dummy values are returned.

112.2.16 SLR/RLR

The IP Phone 221x does not support the UNIStim messages used to adjust the SLR and RLR of the set. This means the default volume feature cannot be supported.

112.3 Administration - Element Manager

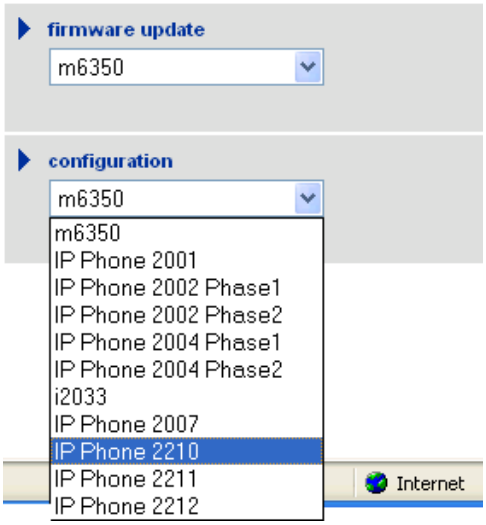

Figure 15

The administration and configuration of the IP Phone 221x uses the same pages which are available for other terminal types.

Figure 16 provides the information of the terminal configuration like feature key attributes, Voice Parameters like default audio profile and default voice codec and RTP Port number for IP Phone 2210. The Default Volume settings have been deleted as this terminal doesn’t support this feature and TFTP port address information is included.

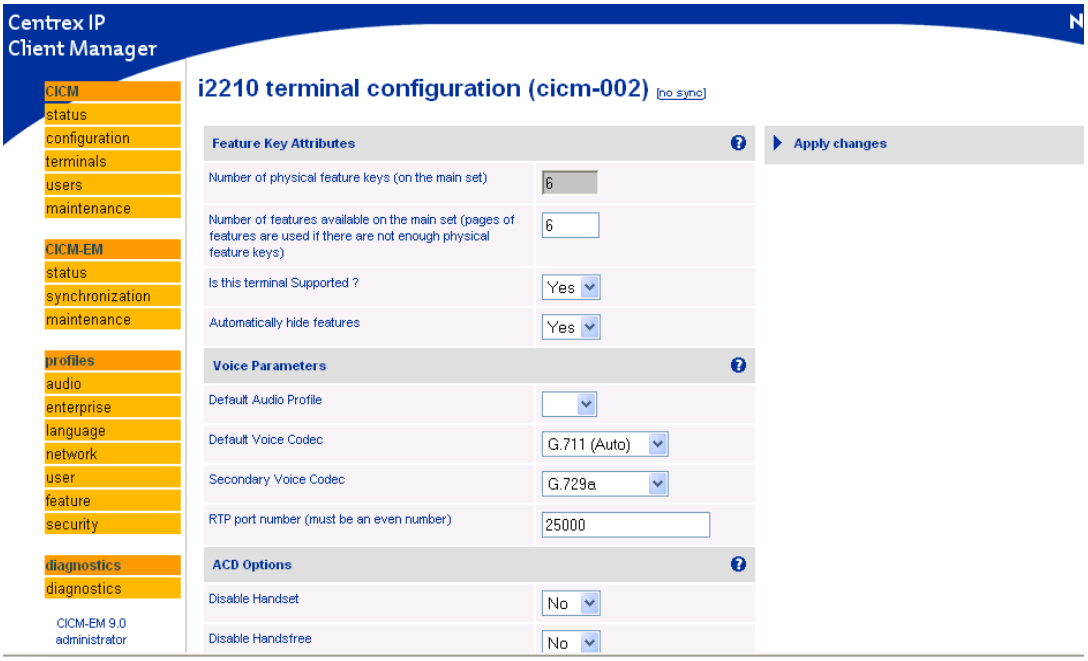

Fig 16 - IP Phone 2210 terminal configuration

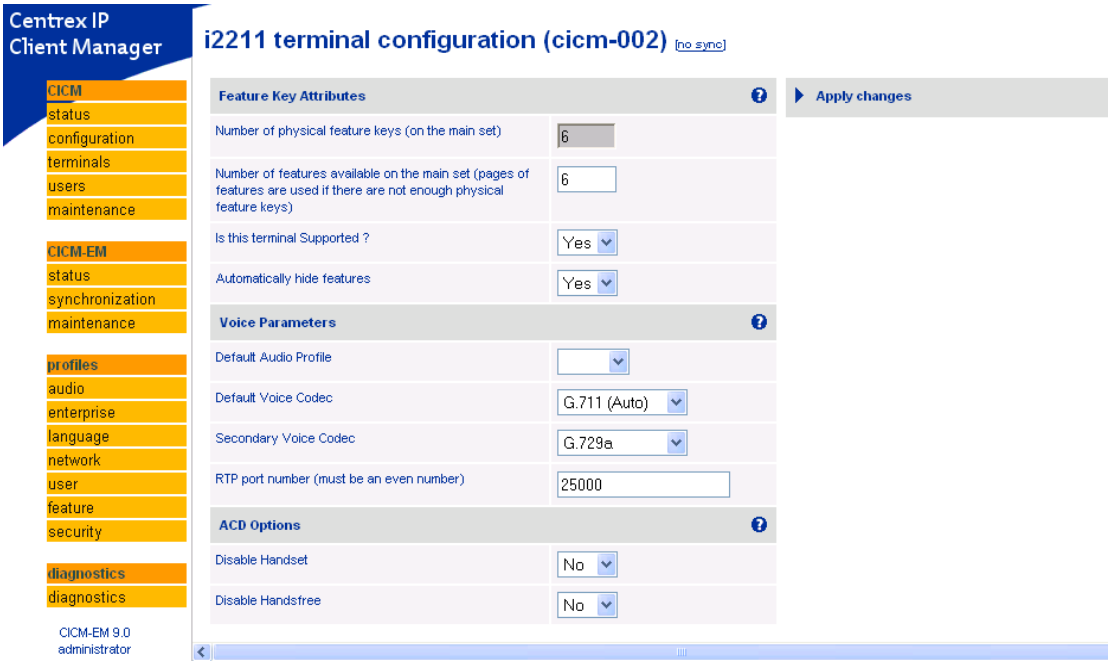

Fig 17 - IP Phone 2211 terminal configuration

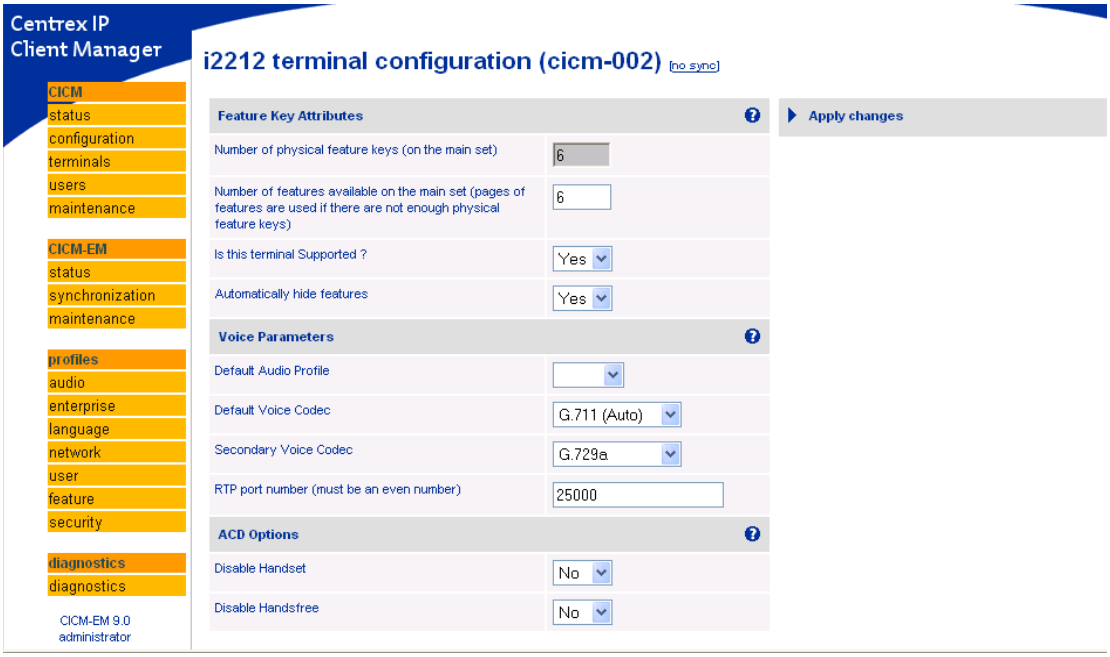

Fig 18 - IP Phone 2212 terminal configuration

112.4 Interactions

112.4.1 Joint session

The IP Phone 221x can join a session with the m6350 Softclient. In this scenario, it will always adopt the master position in their master/slave relationship. In this case, the IP Phone 221x will function in the same manner as the IP Phone 2004.

IP Phone 221x doesn’t support a joint session with another IP Phone 200x or 221x terminal.

112.4.2 SRG Support

The Survivable Remote Gateway (SRG) solution is based on the Business Communications Manager (BCM) platform and technologies. It allows distribution of trunking across the WAN so remote users can get dial tone from their local central office or from any other IP Telephony gateway hosted by CS2K. Local telephone numbers can be published, supporting a local presence within the community the remote office supports. This capability can also reduce unnecessary toll charges and provides required local trunking for Emergency 911 calls. Additionally, the Survivable Remote Gateway provides a full suite of IP based data and routing capabilities including Network Address Translation (NAT), DHCP, Web caching and firewall. The IP Phone 221x supports SRG same as IP Phone 2004.

112.4.3 Unistim Security

The IP Phone 221x does not support UNIStim security.

112.5 Software Requirements or Dependencies

The terminals IP Phone 221x do not support UFTP upgrades as a result only TFTP server is used.

112.5.1 Firmware Download

The IP Phone 221x Terminals have upgradeable firmware. The firmware may be upgraded using TFTP only as UFTP is not supported by the terminal.

The TFTP server address is set as part of terminal configuration either from DHCP server or manually entered.

The TFTP server (RFC 1350) holds the software images for IP Phone 221x and 2245 server. Whenever a wireless handset boots it checks for the firmware version and if it's different download the new version. In a similar way whenever a 2245 reboots or is manually reset it checks for the version against the software available in the TFTP server and if it's different the new firmware is downloaded.

- The time taken for a handset to check the version of software against the one available in TFTP server is less than 2 seconds.
- If the TFTP server is offline or unreachable the 221x tries for about 10 seconds before giving up and using its existing version of firmware.
- The 221x firmware downloading process takes about takes about 30 seconds.
- The TFTP server must be capable of supporting multiple TFTP sessions.
- Software updates for the Nortel 2245 Telephony Manager and Nortel 221x Wireless Handsets should be installed into the root directory of the TFTP server.

The firmware download for the 221x terminals via the CICM is not supported. 221x terminals are blocked to download the firmware through the CICM.

The Element manager is adapted for the 221x terminals to indicate that the firmware downloads via CICM is not allowed. They would be required to download the firmware from the TFTP server mentioned in the Terminal configuration page.

Fig 19 IP Phone 221x terminal firmware configuration

112.6 Hardware Requirements

IP Phone 221x, 2245 server 2246 Applications Gateway, 2230 Access point, 2270 WSS and SN09 CICM required.

2245 Server Overview:

Fig 20 2245 Server

The 2245 acts as a proxy for the wireless handsets and provides several services for the handsets. It should be connected to the same subnet as the wireless handsets. The handsets always communicate voice and signaling directly with the 2245 using the proprietary SVP protocol.

SVP is required for QoS because the current IEEE 802.11b wireless LAN standard provides no mechanism for differentiating audio packets from data packets

Note: **Note**. IP multicast addresses are used by the 2211 push-to-talk (PTT) feature. This requires that multicasting be enabled on the subnet used for the 2211 telephones and the 2245.

112.7 Functional Description

The 2245 provides the following services to the handsets:

- It acts as a proxy for every handset, that is all UNIStim signaling and RTP media to /from the wireless handset pass through the 2245 server. Except for the initial DHCP and TFTP sessions the handsets only communicate with the 2245 server.

Each 2245 server is configured with an IP address which all of the handsets communicate with. In addition, each 2245 is configured with a pool of addresses. When a handset registers with a 2245, it is assigned one of the addresses from the pool. All communication between this 2245 and wireless sets is always done via its pool address. In this sense the 2245 acts as a NAT.

Note: Note: The 2245 has a single physical Ethernet interface and MAC address so all of the IP addresses are mapped to a single MAC address.

SVP is required for QoS because the current IEEE 802.11b wireless LAN standard provides no mechanism for differentiating audio packets from data packets.

- The RTP packets between the handset and the 2245 server always contain 30 msec worth of voice no matter what has been configured on the call server. The 2245 server repackages the RTP packets to conform to the size which has been configured in the call server. This provides more efficient use of the available RF bandwidth at the expense of slightly increased jitter and latency.
- The 2245 server is configured with a maximum allowable number of simultaneous media streams on a single access point. The 2245 server keeps track of the number of media streams on each AP and blocks calls to / from a set which would exceed the configured capacity.
- There is also a keep alive packet exchange which runs between the handset and the 2245 every 30 seconds. If the handsets detects the 2245 server is unreachable it will reset and attempt to re-establish a connection with the Master 2245 server.

If the call originates from a wireless which is on a bandwidth restricted AP the caller hears a warning tone and the call is blocked.

If a set is mobile and moves into an AP which is already at capacity the handset will remain associated with an AP that has sufficient bandwidth. This could result in degraded signal and voice quality and ultimately a call could be dropped.

Call Server. A CS2K server with SN09 load running on it.

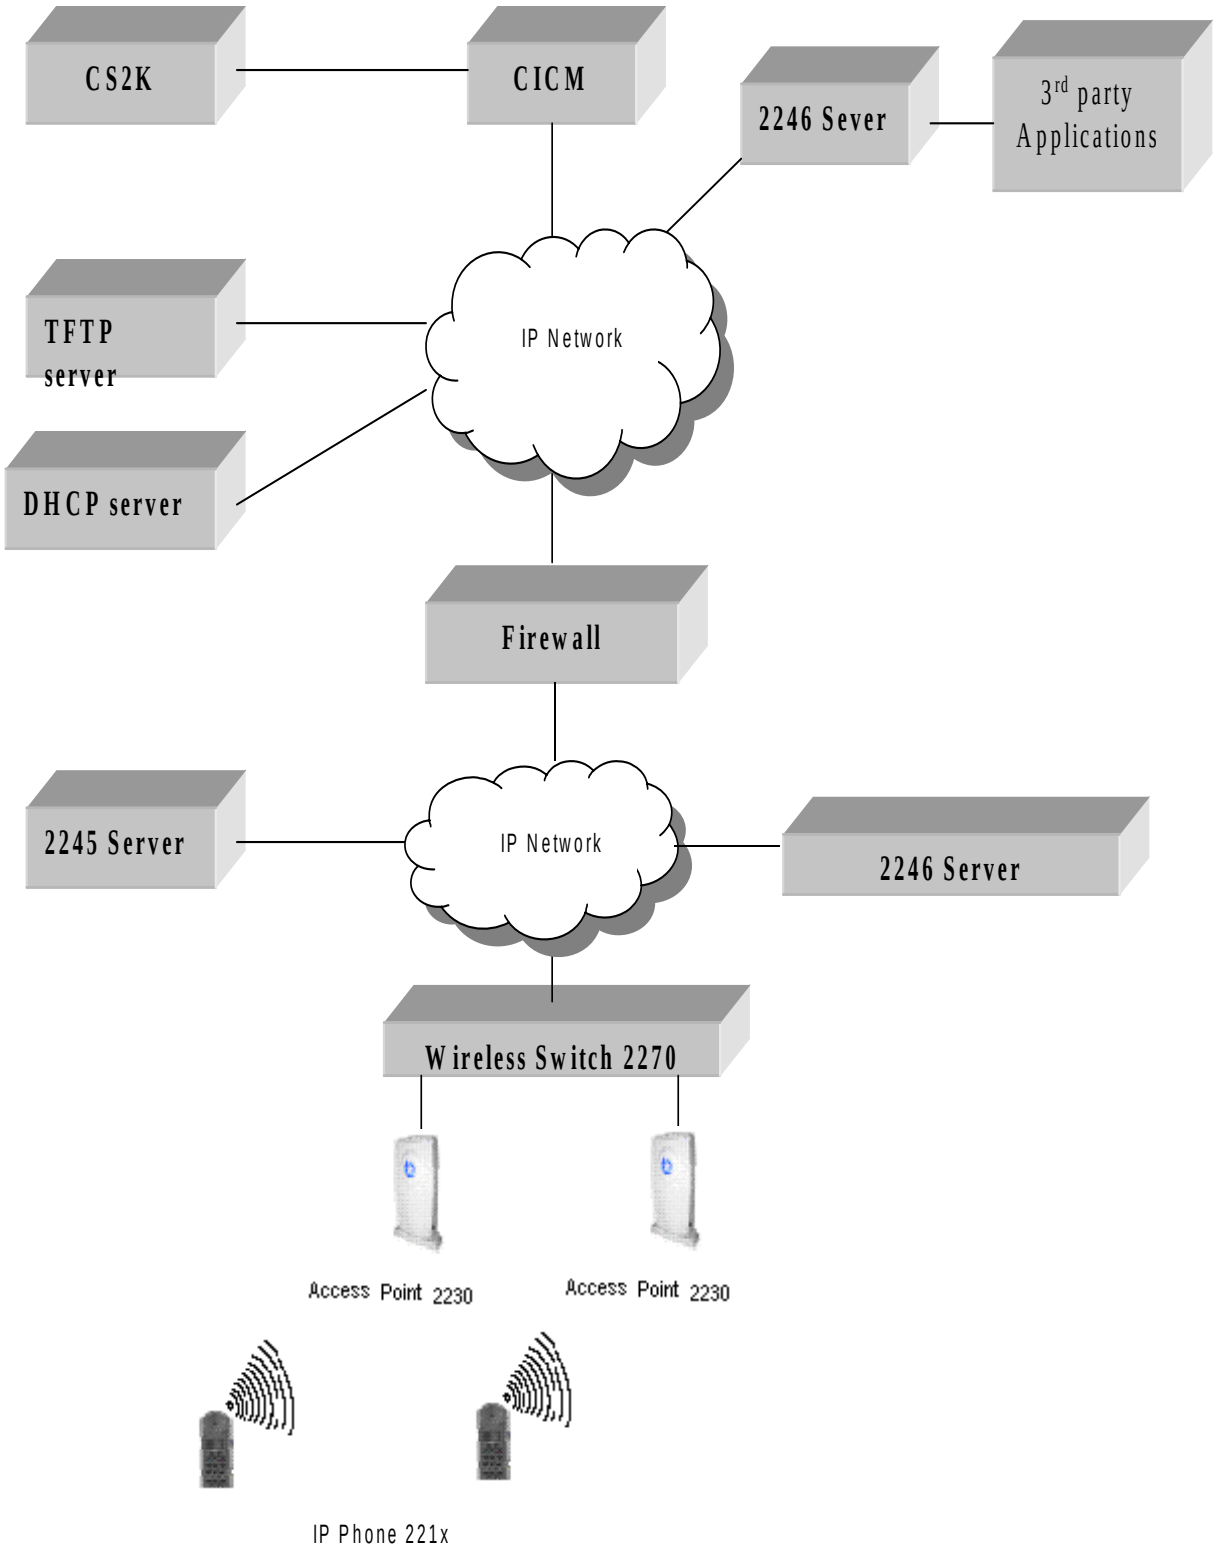
2246 Applications Gateway. This device provides an access gateway so that 3rd party applications can have access to the wireless handsets.

2230 Access Point. An 802.11b access point. For best QoS performance the Access Point should be SVP compliant such as the Nortel 2230 Access Point.

2270 Wireless Security switches: 2270 act as aggregation points for a number of access points or ports and are the gateways from the Wireless LAN into the wired LAN. 2270 allows the phone to roam from subnet to subnet but retains their IP address.

A Wireless handset system is shown in Figure 21:

Figure 21 Wireless Handset system



112.8 Glossary

AP	Access Point
CICM	Centrex IP Client Manager
DHCP	Dynamic Host Control Protocol
PTT	Push To Talk
RTP	Real Time Protocol.
RTCP	Real-time Transport Control Protocol

113: Functional description (FN): A00010024

Nortel Carrier Grade Linux kernel emergency pool, A00010024

113.1 Description

The basic concept of the proposed design is to maintain a kernel emergency memory pool that will be released at the instant where normally the Linux OOM killer would run and thus delaying unpredictable behavior.With the proper notification mechanism and the right threading model it will be feasible to have an application responding to critical condition and take the proper action.

The Memory pressure on the MPE depends largely on the non-deterministic network conditions the box is exposed to. Under extreme pressure the MPE software exhaust the entire memory on the system and die as of a result of OOM killer. It should then be clear that MPE need a more deterministic way to react to such a condition. Given the huge number of different scenarios where the memory can be exhausted, it's impossible to fine tune the OOM algorithm to be 100% deterministic. In other words, MPE needs predictable early warning

113.2 Limitations and restrictions

It's up to the application to properly engineer the threading/scheduling model in order to respond in time to the critical out-of-memory notification as the only guarantee of that feature is to delayed a possible OOM situation.

113.3 Interactions

The proposed design involved some modification to SWMON and the Linux kernel. SWMON has already the capabilities to monitor memory usage and generate alarm (Minor Major Critical) to an application that register through HAPI. The actual monitoring capabilities are too slow to catch fast memory consumption and need to be enhanced by using asynchronous notification from the kernel..

113.4 Glossary

Term	Description
OOM	Out Of Memory
OOM killer	Kernel thread that kill user process when the system run out of memory.

Term	Description
Kswapd	Kernel thread that reclaim memory to the system

114: Functional description (FN): A00010168

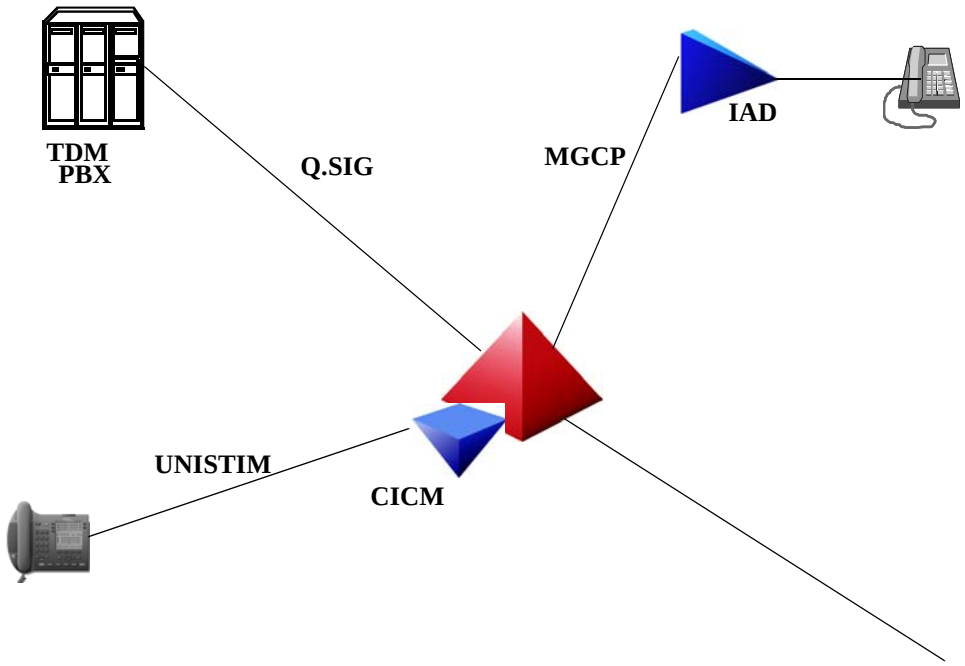
114.1 Feature name and Feature ID

H.323 support for COnnected Line Presentation/COnnected Line Restriction (COLP/COLR).

114.2 Description

This feature is to support COLP/COLR on International H.323 Gateways.
In the context of H.323, QSIG (Q-reference point SIGnalling) is a private (i.e. corporate) network signaling protocol for communication between ISDN Private BranchExchanges (PBX). In respect to H.323 GWs Q.SIG will be used between H.323 and the core. COLP/COLR are existing QSIG functionalities. No new COLP/COLR capabilities are introduced by this feature.
Please refer to ìFigure 1 COLP/COLR Supplementary Servicesî on page 30.

Figure 1: Agent Interworkings over which COLP/COLR Mapping will be supported



2.2.1 COnnected Line Identification Presentation

COnnected Line Identification Presentation (COLP) supplementary service (SS) provides the calling party with the possibility to receive the connected users number.

COLP has the following functionalities:

Provides the calling user with the connected number (CNN).

The CNN IE is provided in the CONNECT message.

The service is provided on a per trunk-group basis, datafilled in table LTDATA.

When the COLP SS is activated, the Connected Party Subaddress Information Element (CNS IE), if provided by the connected user is included in the CONNECT message if COLR is not activated.

For a Private call provisioning is not required for the presentation of the CNN or the CNS IEsí. Whenever a CNN IE and CNS IE are received they are transparently passed on.

Supposing no information is provided by the connected user, the network provides the Default Number associated with the connected user. The DFLTCNN option in table LTDATA stores the Default Connected Number for the terminating side. If this is not datafilled then no digits are sent across to the originating side.

If the Presentation number is datafilled, then COLP enables the originator to receive the connected presentation number.
If NOSCRN option is datafilled, then the COLP enables the originator to receive the unscreened connected number.

For a call originated by a QSIG trunk which does not have COLP datafilled in table LTDATA, the COLP SS is not supported. To invoke the COLP SS, the originating QSIG trunk must be defined with the COLP option in table LTDATA. Please refer to ìTable 1 Sample Datafill for COLP in Table LTDATAon page 31.

Table 1 Sample Datafill for COLP in Table LTDATA

LTDKEY LTDRSLT
ISDN 4 SERV SERV N N ALWAYS ALWAYS **COLP**

Default Connected Number :
In case, the COLP SS is activated for the originator QSIG trunk and no information (CNN IE) is provided by the connected user or the information provided is invalid, the network provides the DeFauLT CoNnected Number (DFLTCNN) associated with the connected userís QSIG access in the destination local network. The default connected number is obtained from the DFLTCNN option in table LTDATA associated with the terminating QSIG trunk. The maximum number of connected number digits is 15.

Refer to the following table.

Table 2 Sample Datafill for Default Connected Number in Table LTDATA

LTDKEY LTDRSLT
ISDN 4 SERV SERV N N ALWAYS ALWAYS **DFLTCNN 6966970**

2.2.3 COnnected Line Identification Restriction

COnnected Line Identification Restriction (COLR) supplementary service (SS) enables the connected party to prevent presentation of its number to the calling party.

COLR has the following functionalities:

- The COLR SS is offered at the terminating end.
- It prevents the presentation of the connected number (CNN).
- The service is provided on a per trunk-group basis. For COLR temporary, the default value (allowed/restricted) can be overwritten on a per call basis.
- It prevents the presentation of the Connected Party Subaddress (CNS).
- The COLR SS is offered by a permanent mode (PERM), or by a temporary mode (TEMP):

PERM mode: The COLR SS is invoked automatically by the network on all calls. If the calling party has subscribed to COLP SS, and the COLR SS datafilled as PERM RESTRICT is invoked and the valid CNN IE is sent from the terminating side, then the calling party receives the Connected Number IE with the indication of ìpresentation restrictedî and the digits not included.

TEMP mode: The COLR SS is invoked on a per call basis. This means that one of the following scenarios occurs, according to the default value set in the network:

a. If the Presentation Indicator (PI) value is supplied into the Connected Number Information Element (CNN IE), then the PI remains as received from the connected user.

b. If the PI value is not supplied into the Connected Number IE, the presentation indicator is set according to the COLR TEMP sub option that could be Allow or Restrict.

Refer to the following table.

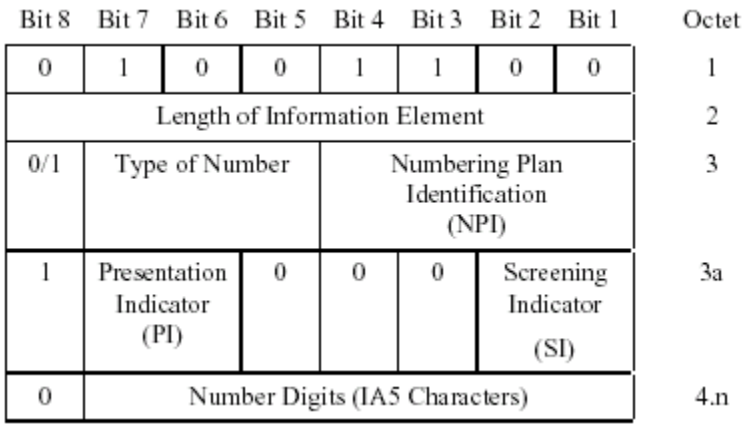
Table 6 Sample Datafill for COLR: Table LTDATA

LTDKEY LTDRSLT
ISDN 3 SERV SERV N N ALWAYS ALWAYS **COLR TEMP ALLOW**
ISDN 3 SERV SERV N N ALWAYS ALWAYS **COLR PERM RESTRICT**
ISDN 3 SERV SERV N N ALWAYS ALWAYS **COLR TEMP RESTRICT**

2.2.4 Values supported for SI, PI, TON, NPI in CNN IE

The connected number information is contained in the optional connected number information element (CNN IE) of the Q.931 connect message. The CNN IE is coded as shown in fig. 6. Please observe that octet 3 can have 0 or 1 value depending upon the usage. The maximum length of this information element is 24 octets. Please refer to ìFigure 5 Connected Number Information Element (CNN IE)î on page 41.

Figure 5 Connected Number Information Element (CNN IE)



The different option values of Screening Indicator (SI), Presentation Indicator (PI), Type Of Number (TON), Numbering Plan Indicator (NPI) as supported on the DMS100, are explained below.

Refer to the following figure.

Figure 6 Option Values

Screening Indicator (SI)

2	1	
0	0	user-provided, Not Screened
0	1	user-provided, Verified, and Passed
1	0	user-provided, Verified and Failed
1	1	Network Provided

Presentation Indicator (PI)

7	6	
0	0	Allow
0	1	Restrict
1	0	Not available

Type Of Number (TON)

7	6	5	
0	0	0	Unknown
0	0	1	International Number
0	1	0	National Number
1	0	0	Subscriber number

Numbering Plan Identification (NPI)

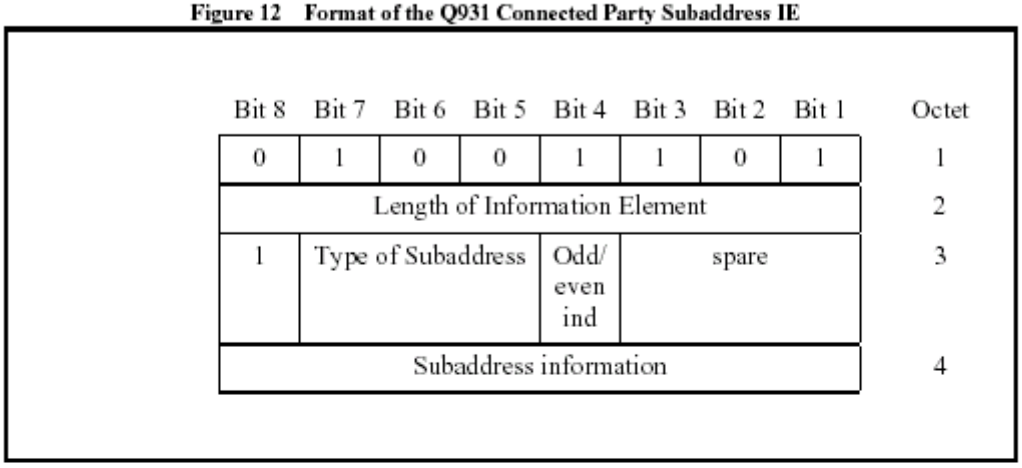
4	3	2	1	
0	0	0	0	Unknown
0	0	0	1	ISDN Telephony Numbering Plan (E164)
1	0	0	1	Private Numbering Plan

An incoming CNN IE at the terminating side is considered as valid only if the NPI field has "Unknown" or "ISDN Telephony Numbering Plan (E164)" values. Otherwise the information is discarded. The CNN fields from CONNECT message are updated at the CM level to reflect the CNN information that is delivered to the originating interface.

2.2.6 Connected Party Subaddress (CNS)

The purpose of the Connected party subaddress information element is to identify a subaddress associated with the terminator of a call. Please refer to "Figure 12 Format of the Q931 Connected Party Subaddress IE" on page 54.

Figure 12 Format of the Q931 Connected Party Subaddress IE



Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Octet
0	1	0	0	1	1	0	1	1
Length of Information Element								2
1	Type of Subaddress			Odd/ even ind	spare			3
Subaddress information								4

For the Connected Party Subaddress the following is done,

- The CNS is mapped to the APP-PSS1 parameter. (For QFT only)
- The CNS is mapped to the ATP parameter in case of ISUP.
- If COLP SS is activated, add the Connected Party Subaddress Information Element to the CONNECT message.
- If COLR SS is activated, the Connected Party Subaddress Information Element is not added to the CONNECT message.
- If the calling user has not subscribed to COLP, then the CNN IE and the CNS info are not sent in the CONNECT message.
- On interworking of QSIG to QSIG, the CNS IE shall be mapped independently of the COLP SS.

The Presentation of the CNS IE depends on the following:

Public call:

- When COLP SS is not subscribed, the CNN IE and CNS IE are not sent to the calling user.

- When COLP SS is subscribed and PI = allowed, the CNN IE and CNS E (if available) are sent to the calling user.

- When COLP SS is subscribed and PI = restrictd, an 'empty/restricted' CNN IE is sent to the calling user. The CNS IE is not sent in this case.

Private Call:

- The CNN IE and CNS IE are mapped transparently.

- Exception for Originating and END PINX:

- When COLP SS is subscribed and PI = restricted, and empty/restricted' CNN IE is sent to the calling user. The CNS IE is not sent in th

2.2.8 Interworkings

Networked services support for interworking QSIG for H.323-based originating/ terminating at a 3rd party based PBX (e.g., Siemens HiPath) should include the following:

. i.COnnected Line Identification Presentation (COLP) supplementary service (SS).
ii.COnnected Line Identification Restriction (COLR) supplementary service (SS).

Networked services support for interworking QSIG for H.323-based originating/ terminating at a Nortel PBX (e.g., BCM50, BCM 200/400) should include the following:

i.COnnected Line Identification Presentation (COLP) supplementary service (SS).
ii.COnnected Line Identification Restriction (COLR) supplementary service (SS)

114.3 Limitations and restrictions

There is no attempt within this feature to map MCDN versions of COLP/ COLR to H.323 or to Q.SIG. This feature merely maps Q.SIG versions of COLP/COLR to H.323 versions of COLP/COLR (and vice versa). The following provide specific examples of messaging in MCDN environments

This feature is implemented exclusively for the support of International H.323 COLP/COLR. Refer to A59027747 QSIG Support for COLP/COLR for additonal restrictions on COLP/COLR.

114.4 Glossary

Table 1:

TERM	DESCRIPTION
CNN	Connected Number
CNN IE	Connected Number Information Element
CNS	Connected Number Subaddress
CNS IE	Connected Number Subaddress Infomation Element
COLP	COnnected Line identification Presentation
COLR	COnnected Line identification Restricton
QSIG	Q Interface Signaling
SS	Supplementary Service

115: Functional description (FN): A00010303

115.1 Feature name and Feature

A00010303- Map Level Service Control Application Programming Interface

115.2 Description

This activity addresses the development associated with enabling in DMS and CS2000, the update and/or query capabilities for the switch based services. With the addition of this set of capabilities, subscribers will have the ability to both query the status and/or programmed information as well as activate/ deactivate and update their corresponding service. Based on the service provider's interface for the end user, it takes out the complexity faced by the user to activate, deactivate, add, delete, change or edit specific data. The command performance will be in the range of 1 to 3 seconds.

Functional Behavior:

For CS2K, the commands issued by the end user will be sent via a 3rd party provisioning server to the OSSGATE via telnet. This is then sent to the SDM(Supernode Data Manager or CS2K Manager) which is the interface to the core for processing. The output will then be sent back and displayed to the end user via the web server. For TDM lines, there is a direct telnet connection between the 3rd party provisioning server and the SDM. This architecture can be used both for DMS and CS2K.

115.3 The Query command

Depending on the feature, the Query command can be used to query different fields such as the status, the list (if present), the delay interval and so on. When issued at the CI prompt, the query command will take the input parameters and call the query procedure for that feature. Depending on whether the feature is present or not, the corresponding return code is output.

115.3.1 QueryRequest

For a query request, the following are the input parameters:

- The DN of the subscriber associated with the given request would be a 10 digit DN.
- The corresponding feature/service would be simple enumerated type similar to the one defined in SERVORD and representing all supported services.
- The list of service attributes being queried would be simple set or enumerated type representing all possible attributes.

115.3.2 QueryResponse

The response will include the following:

Values corresponding to the service attributes queried.

- Only attributes for a single service per query will be supported in SN09.
- For list queries, the privacy indicator should be checked prior to displaying the corresponding DN.

115.3.3 List of supported Query Attributes

Table 1 List of supported Query Attributes

Enumeration	Return Value	Description
status	active or inactive	Query the status of the corresponding service
list	list of DNs 10 digits in length with/ without priv. ind.	Query all entries in the corresponding service's screening list.
listSize	positive integer less than 255	Query the number of entries in the corresponding service's screening list.
forwardDN	DN upto 30 digits in length	Query the forwarding DN of the corresponding call diversion service.

Enumeration	Return Value	Description
delayInterval	Positive integer between 1 and 10	Query the delay Interval of the corresponding service.This represents the number of rings.
scList	List of DNs variable in length up to 30 digits	Query all entries in the corresponding Speed Call list
all	Some aggregate of the above	Query all attributes of the corresponding service.

115.3.4 Service to Query attribute matrix

Each service belongs to a group from group1 to group9. These groups are based on the attributes of each service. The matrices below show the attributes present for each service.

Table 2 Service to Query Attribute matrix

Service	Status	Delay Interval	List	List Size	Forward DN	Speed Call List
MWI	X					
VMWI	X					
AMWI	X					
ACRJ	X					
ACB	X					
AR	X					
CSMI	X

115.3.5 Error codes for the Query command

Table 3 Error codes for the Query Command

Return Code	Description
Failure - Invalid_Dn	DN entered is not valid.
Failure - Unavailable_Resources	The service is not subscribed on the DN.
	The feature SOC is idle.
	SLE SOC is idle.
Failure - SOC_Idle	The svcntrl SOC is idle.

115.3.6 Query Examples

Syntax to query the status of SCRJ for 6136631001

>svcntrl query 6136631001 scrj status

Status - Service_Active

Syntax to query the SCRJ list for 6136631001

>svcntrl query 6136631001 scrj list

List_Dn -

6136634567; 6136638901; 6136671001

6136671023; 6136789021; 6136779001

6136772021;

Syntax to query SCRJ for 6136631001

>svcntrl query 6136631001 scrj all

Status - Service_Active

List_Size - 7

List_Dn -

6136634567; 6136638901; 6136671001

6136671023; 6136789021; 6136779001

6136772021;

If the DN is not provisioned with the service, then the following error message displayed:

>Syntax to query status of CSMI on 6136671021

>svcntrl query 6136671021 CSMI status

Failure - Unavailable_Resources

115.4 The Update command

Depending on the feature, the Update command can be used to update different attributes such as the status, the delay interval, the forward DN and so on. When issued at the CI prompt, the Update command will take the input parameters and call the Update procedure for that feature. Depending on whether the feature is updated or not, the corresponding return code is output.

115.4.1 Update Request

For an Update request, the following are the input parameters

- The DN of the subscriber associated with the given request will be a 10 digit DN.
- The corresponding service will be represented as a simple enumerated type similar to the one defined in SERVORD and representing all supported services.

- The action to be taken will be represented as a simple enumerated type representing all supported actions.

115.4.2 Update Response

Will include the following:

Return codes indicating non availability of the API (ie is the CI SOC idle)

- The return code will be in the form of readable text.

Return codes indicating the confirmation or denial of the Update request.

- Simple enumerated type representing all supported Update return codes.
- The return code will be displayed as readable text.

  For example, confirmation from an Update request to activate CSMI would be represented as “Success - Service_Activated”.

115.4.3 List of supported Update Actions

The following table gives the list of actions that is supported for each service.

Table 4 List of supported Update Actions

Enumeration	Description
activate	Activate corresponding service.
deactivate	Deactivate corresponding service.
delayInterval	Set delay interval for corresponding service.This is the number of rings.
adddn	Add specified DN to corresponding service’s screening list.
deletedn	Delete specified DN from corresponding service’s screening list.
deleteAlldn	Delete all DNs from corresponding service’s screening list.
deleteAllPrivdn	Delete all private DNs from corresponding service’s screening list.
setfwdDN	Set forwarding DN for corresponding call diversion service.
clearFwdDN	Clear forwarding DN for corresponding call diversion service.
toggle	Toggle status of the corresponding services.
invoke	Invoke the corresponding service.
changeList	Change a specified speed call cell entry.

115.4.4 Service to Update Action matrix

Each service belongs to a group from group1 to group9. These groups are based on the attributes of each service. The matrices below show the attributes present for each service.

Table 5 Service to Update Action matrix

Service	Activate	Deactivate	DelayInterval	Addn	Deletedn	DeleteAlldn	Delete All Privatedn	Set Fwd Dn	Clear Fwd DN	Toggle	Invoke	Change List
MWI	X	X										
VMWI	X	X										
AMWI	X	X										
ACRJ	X	X										
ACB	X	X										
AR	X	X										
CSMI	X	X										
CWT	X	X

CFDVT			X									
CNDB										X		

Service	Activate	Deactivate	DelayInterval	Addn	Deletedn	DeleteAlldn	Delete All Privatedn	Set FwdDn	Clear FwdDN	Toggle	Invoke	Change List
CNAB										X		
COT											X	
CCW											X	
SCS												X
SCL												X
SCU												X

Update Examples
Syntax to activate Call Forward BusyLine on 4164731051

>svcntrl update 4164731051 cfb activate

Success - Service_Activated

Syntax to clear the forward DN on 4164731051

>svcntrl update 4164731051 cfb clearFwdDn

Success - ForwardingDn_Cleared

>svcntrl update 4164731051 cfb setFwdDn dn 4164631001

Success - ForwardingDn_Set

Error conditions:

If we try to activate an already activated service

>svcntrl update 4164731051 cfb activate

Failure - Service_Already_Active

If the user tries deleting a list which is empty, the response would be

>svcntrl update 4164731051 simring deleteallDN

Failure - List_Is_Empty

If the SOC for SPRING (call forward ringing) is not turned on, the response would be

>svcntrl update 4164731051 cfdvt delayInterval 4

Failure - Unavailable_Resources

Ex6: If the parameters entered are insufficient

>svcntrl update

The response would be:

Failure - Missing_Parameter

115.4.5 List of supported Update responses

Table 6 List of supported Update responses

Response	Meaning
Success - Service_Activated	Successful activation of the service.
Success - Service_Deactivated_or_Cancelled	Successful deactivation of the service.
Success - AnonymousEntry_Added	Successful addition of a private no. to the list of a DN.
Success - PublicEntry_Added	Successful addition of a DN to the list of another DN.
Success - AnonymousEntry_Removed	Successful deletion of a private number from a DNs list.
Success - PublicEntry_Removed	Successful deletion of a DN from a DNs list.
Success - All_Anonymous_Entries_Removed	Successful deletion of all private DNs from the list.
Success - All_Entries_Removed	Successful deletion of all DNs from the list.
Success - ForwardingDn_Set	Successful setting of a FwdDN to another DN.
Success - ForwardingDn_Cleared	Successful clearing of a FwdDN from another DN.
Success - DelayInterval_Updated	Successful updation of delay interval of a DN.
Failure - Service_Already_Active	Not updated because the service is already active on the DN.
Failure - Service_Not_Activated	Gives this response because the service might be inactive and the user is trying to deactivate or in the case of ACB/AR if the feature queue is not present.
Failure -Invalid_Forwarding_Dn	FwdDN not set because the FwdDN did not pass validation.

Response	Meaning
Failure - List_Is_Empty	When trying to delete a DN from the list of another DN and if the list is empty.
Failure -List_Is_Full	When trying to add a DN to the list of another DN and if the list is full and cannot accommodate more DNs.
Failure - Public_Dn_Already_On_List	If the DN you are trying to add to the list of another DN is already present.
Failure - Anonymous_Dn_Already_On_List	If the private DN you are trying to add to the list of another DN is already present.
Failure - Dn_Not_On_List	If the DN you are trying to delete is not on the list.
Failure - No_Match	When trying to update the delay interval, if the ring control is not programmable ring type.
Failure - Unsuccessful_Update	This message comes when the update is not successful and for different features and actions, are different.
	For ACB/AR, activation of the feature is not supported.
	For CFB, if Fixed or Programmable version is not provisioned.
	For CFBL & CFDA, with control N type.
	FOR CFDA if IECFD is provisioned or if CFD Normal is provisioned.
	For Speed Call, if SCU is provisioned.
	For services that use SLE, if SLE datafills are missing in Table CUSTSTN.

115.4.6 Error codes for the update command

Table 7 Error codes for the Update Command

Return Code	Description
Failure - Invalid_Dn	DN entered is not valid.
Failure - MSRID_Does_Not_Match_User_Profile	For all types of MWT an Msr Id has to be input.This will be validated against Table MSRTAB.If there is a mismatch, then it returns this code.

Return Code	Description
Failure - Unavailable_Resources	The service is not subscribed on the DN.
	The feature SOC is idle.
	For ACB and AR, checks the validity of the feature and if the feature is not allowed gives this response.
	For ACRJ, COT if universal access is not permitted.
	For CFB, if IECFB is provisioned.
	For CFD, if IECFD is provisioned.
	For CFU, if CFU/CFI/CFF is not provisioned.
	For CNAB & CNDB, if the call is not up.
	FOR MWI, if EMW or CALLOG is assigned to the line.
	The SLE SOC is idle.
	Deactivate MWT when MWT is not active
Failure - SOC_Idle	The SVCNTRLl SOC is idle.

115.5 Error responses for Invalid Entries

Table 8 Error responses for invalid entries

Return Value	Description
Failure - Invalid_Action	When any other value other than update or query is entered after svcntrl.
Failure - Invalid_DNformat	When the DN entered has alpha numeric values or if the DN is not of 10 digit form.
Failure - Unrecognized_Service	When the service entered is invalid.
Failure - Invalid_Attribute	When the attribute entered for that service is invalid.
Failure - Invalid_Attribute_Parameter	When the parameters for the attributes are specified incorrectly. For e.g., if the value of delay interval to be updated is greater than 10.
Failure - Missing_Parameter	When an incomplete command is issued, i.e. if the service, attribute, or any of the parameters are missing.

Ex 1: When the action given is not update/query

>svcntrl updation 6136631001 acrj activate

The response would be:

Failure - Invalid_Action

Ex2: If the DN is invalid

>svcntrl query abc6790123 drcw list

The response would be:

Failure - Invalid_DNformat

Ex3: If the DN entered is not 10 digit

>svcntrl query 6631001 cfb ForwardDN

The response would be:

Failure - Invalid_DNformat

Ex4: If the service is not valid

>svcntrl update 6136671021 cssi activate

The response would be:

Failure - Unrecognized_Service

Ex5: If the attribute is not valid for that service

>svcntrl update 4164671021 cndb FwdDn

The response would be:

Failure - Invalid_Attribute

EX7: If the attribute parameters are invalid

>svcntrl update 4164671001 cfdvt delayInterval 65

The response would be:

Failure - Invalid_Attribute_Parameter

Ex6: If the parameters entered are insufficient

>svcntrl update

The response would be:

Failure - Missing_Parameter

>svcntrl query scs

Failure - Missing_Parameter

115.6 Hardware Requirements or Dependencies

In order to enable this capability for affected subscribers, the following must be present in the provider's network

- Some Provider Network Server designed to support service queries/ updates via some Web or PC Client based interface.
- SESM/OSSGATE - An application that is used for the provisioning and maintenance of lines, trunks etc. The OSSGATE passes on the command information to the SDM.
- SDM /CS2K Core Manager - The SDM is an interface to the core. It takes in the commands given by the SESM and passes them onto the core and also takes the responses from the core and gives it to the SESM.

115.7 Software Requirements or Dependencies

The new SOC XXX will control the CI interface to Service Management. This XXX SOC will be independent of the AIN TCAP Service Management SOC control. The following table gives the possible supported state of both the SOCs:

Table 9 Supported SOC States

AIN SOC	Service Management SOC	Implication
ON	ON	Both interfaces will be active at the same time.
IDLE	IDLE	Both interfaces will be inactive at the same time.
ON	IDLE	AIN interface to be active and SVCNTRL to be inactive.
IDLE	ON	AIN interfaces to be inactive and SVCNTRL to be active.
ON for some	ON	Some combination of AIN interfaces active and SVCNTRL active.
ON for some	IDLE	Some combination of AIN interfaces active and SVCNTRL inactive.

115.8 Limitations and restrictions

This capability will be applicable only to North American loads. If some invalid characters are entered after a valid command, then the command will not be rejected. The command will be processed with the valid input. Refer to A00004036 FN for the limitations and restrictions of each service.

115.8.1 List of supported services/features

The following table gives the list of supported services/features the market that they are valid for.

Table 10 Supported Services/Features

Service	Servord Acronym
Message Waiting Indicator [a]	MWI
Visual Message Waiting Indicator <Superscript1>a.	VMWI
Audio Message Waiting Indicator <Superscript1>a.	AMWI
Anonymous Call Rejection	ACRJ
Automatic Callback	ACB
Automatic Recall	AR
Call Screening<Superscript1>a.	CSMI
Outside Calling Area Alerting<Superscript1>a.	LDSA
Calling ID delivery & Suppression	SUPPRESS
Call Waiting(requires CWTACT)	CWT
Make Set Busy	MSB
Distinctive Ringing Call Waiting [b]	DRCW
Selective Call Rejection<Superscript1>b.	SCRJ
Simultaneous Ringing	SIMRING
Call Forward Dont Answer [c]	CFDA
Call Forwarding Variable	CFU
Call Forward Busy Line[d]	CFB
Selective Call Acceptance <Superscript1>a.	SCA
Selective Call Forwarding<Superscript1>a.	SCF

Service	Servord Acronym
Call Forwarding Ringing Control<Superscript1>b.	CFDVT
Calling Number Delivery Blocking	CNDB
Calling Name Delivery Blocking	CNAB
Customer Originated Trace	COT
Cancel Call Waiting	CCW
Speed Calling Short	SCS
Speed Calling Long	SCL
Speed Calling User	SCU

a. North American Market Only
b. North American Dialplan Only

c. This service will include both CFDA and CFD.
d. This service will include both CFBL and CFB.

115.8.2 List of supported DN specifiers

Table 11 Supported DN Specifiers

Enumeration	Description
user	DN being added or deleted provided explicitly by the subscriber.
speed call	Add/Delete the DN in the subscriber's corresponding speed call entry
icm	Add/Delete the DN in the subscriber's Incoming Call Memory.

A00004036 - Off Board Service Control

116: Functional description (FN): A00010329

116.1 Feature name and Feature ID

A00010329 - Remove ASPEN protocol support on PVG

116.2 Introduction

In 1999, when MG7K/MG15K was first introduced, ASPEN was used as the only Signalling and Call Control protocol between Gateway Controller (GWC) and the MG7K/15K Gateway. Several years later in 2003 (SN06), standards based H.248 was introduced. Over time, H.248 has been the protocol of choice for most customers.

From SN09/PCR7.1 onwards, ASPEN will no longer be supported in a Succession solution. This feature removes the ASPEN protocol support on PVG from SN09/PCR7.1.x onwards on Switched AAL2 and Switched IP, NT0482AB VSP2 7K, NTHW87AB VSP2 15K, NTHW84AA, VSP3, and NTHW77AA VSP3-o.

During HSM, customers cannot upgrade to SN09/PCR7.1 with ASPEN provisioned. Appropriate error message is displayed informing customer to upgrade to H.248 prior to upgrading to SN09/PCR 7.1.x. The craft person is required to upgrade to H.248, prior to migrating to SN09/PCR7.1.

116.3 Terminology

The list of various terminology used in the document are:

- PVG Packet Voice Gateway
- GWC Gateway Controller
- CAS Component Administration System
- PCR Passport Carrier Release
- H.248 A Media Gateway Control Protocol
- Nsta NarrowbandServicesTrunkOverATM
- MG Media Gateway
- Vgcp VoiceGatewayControlProtocol
- HSM Hitless Software Migration

117: Functional description (FN): A00010452

117.1 Feature name and Feature ID

A00010452 LANComm Multi-home Enhancements

117.2 Description

This feature will add enhancements to existing functionality to allow the Ethernet Interface Unit (EIU) to integrate better into existing customer network topologies. By extending the Internet Protocol (IP) address assignment range and relaxing the current rule that govern what IP addresses can be assigned to EIUs equipped as interfaces, this feature will provide the ability to home the core onto any IP network regardless of it's IP class. In addition, this feature allows the SUBNET value for any interface to be independent of all other entries data filled on the core.

In addition to increased flexibility in the assignment of IP interfaces, enhanced checking will be added to table control for table IPNETWRK that will vlidate each entry to make sure that as entered, the interface will perform as expected. Some of these enhancements include:

SUBNET value range checking based on the IP class

Prevention of overlapping IP subnets with different SUBNET values

Special handling of interfaces with the IRM_INTERFACE parameter

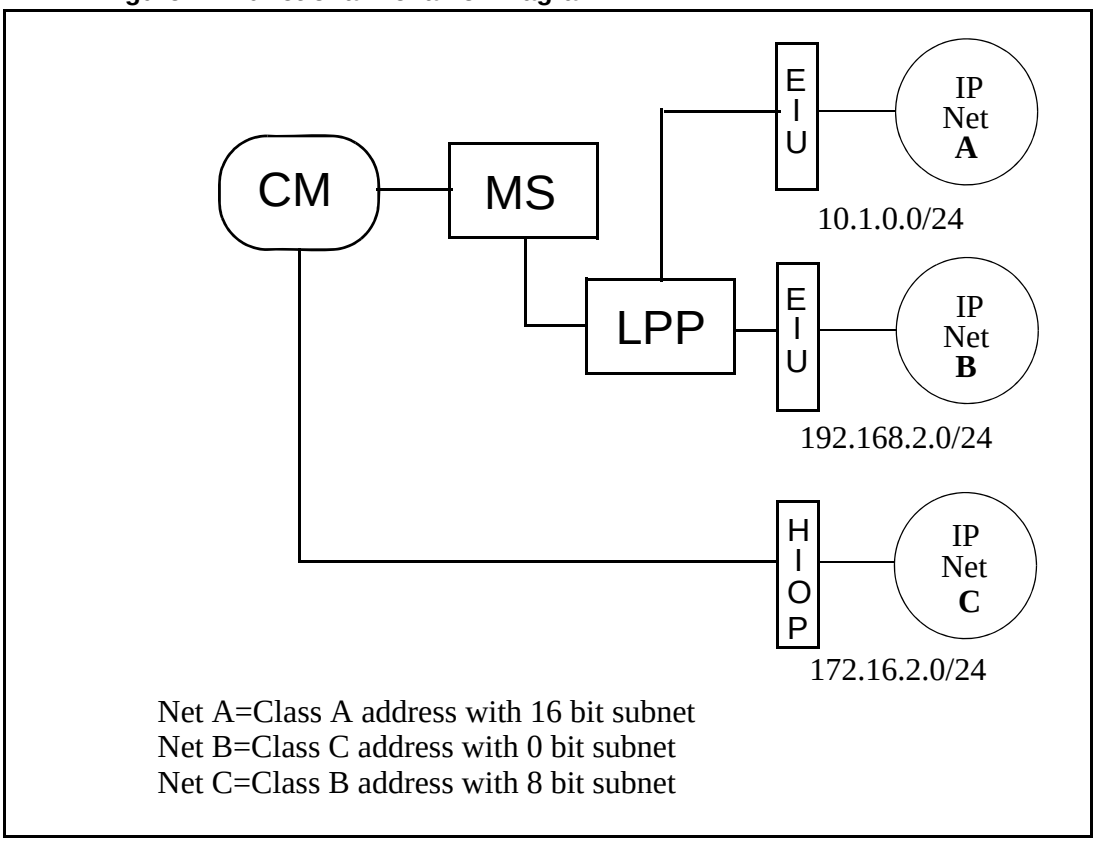
Entry with IRM_INTERFACE can not have DFLT_INTERFACE Y

Current network topologies used for Succession solutions have the EIUs homed onto the customer OAM&P network. The HIOP is normally homed onto the call processing network. These two networks traditionally are in different address spaces and network class. Feature A00002510 introduced the ability to assign an HIOP as an interface in table IPNETWRK. This was done to allow the HIOP to use the Transmission Control Protocol (TCP) transport layer in the LANCOMM TCP/IP stack.

In order to support such an arrangement, the LANCOMM stack needs to be able to support multiple network classes for EIUs and HIOPs equipped as interfaces to the XA-Core. This will require changes to the internal data structures that are used to perform such things as source and destination IP address validation for incoming and destination IP address validation for outgoing packets. This feature will make the necessary changes to support

homing the XA-Core onto different networks regardless of their class. Figure 1 shows a typical multi-homed arrangement that can be support by this feature.

Figure 1 Functional Behavior Diagram



117.3 Hardware Requirements or Dependencies

None.

117.4 Software Requirements or Dependencies

None.

117.5 Limitations and restrictions

This feature will not alter the way in which an Ethernet Interface Unit (EIU) equipped as a router (EIUs data filled in table IPROUTER) currently function. The restrictions that currently exist for EIUs equipped as routers are that all IP addresses for all EIUs equipped as routers must reside in the same IP class and network.

117.6 Interactions

None.

117.7 Glossary

Term	Description

118: Functional description (FN): A00010490

118.1 Feature name and Feature ID

A00010490CS2M - Adding Support MCPN905-270 card in SAM21 EM (Corrective)

118.2 Purpose

In this CAF, two new variants of the Motorola MCPN905 hardware for the Universal Signaling Point (USP) and Call Agent (CCA) are being introduced. The new hardware for USP is the MCPN905 866MHZ 512MB card, and the new hardware for CCA is the MCPN905 1GHZ 2GB. This feature is an add-on to the A00007564 feature which introduced the MCPN905 1GHz 512MB card for the GWC Software. Since all the maintenance actions supporting the 905 card are already added in the feature A00007564, this CAF will only add the CCA enable on MCPN905 1GHZ 2GB to the SAM21 EM.

After this feature, there are total three types of MCPN905 card supported:

- 905 for GWC = 905-240
- 905 for USPc = 905-220
- 905 for CCA = 905-270

118.3 Problem symptoms

This feature is a function enhancement feature.

1. Enable support for the MCPN905-270 card in SAM21 EM.

2. Add the CCA service provision on MCPN905-270 card.

3. Verify that CCA is fully supported by MCPN905-270 and USPc is fully supported by MCPN905-220.

118.4 Description of fix

This feature introduces the MCPN905-270 card support to SAM21 EM. The card supporting and related maintenance actions for this card are added in the feature A00007564. This feature enables the customer to provision CCA to this card, and to do the maintenance test to verify whether this card can work well with the SAM21 shelf and that USPc and CCA can be provisioned successfully.

118.5 Customer facing documentation changes

N/A

118.6 Enabling the MCPN905-270 for CCA

Complete the following steps.

1. Insert into the SAM21 shelf a MCPN905-270 card with 2GB of memory.

2. Verify that the Shelf View displays the card on the corresponding slot and that it marks the card “No Service”.

3. Right click the card and bring up the card view.

4. Switch to the equip tab, verify the card name is “MCPN905” and the memory is “2048M”.

5. From the Shelf View of the SAM21 EM client, right click the card’s slot and then select “Assign Service”.

6. A pop-up dialog entitled “Service Assignment” appears that includes a “Call Agent” option.

7. Select “Call Agent” and provision the card.

8. Verify that the first two MAC addresses are displayed on the provision dialog.

9. Verify that the Shelf View changes the display for that card from “No Service” to “Call Agent”.

10. Verify the bootptab information for this GWC card is stored in SSPFS (/ etc/ bootptab).

11. You have completed this procedure.

119: Functional Description (FN) A00010567

119.1 Feature name and Feature ID

Corrective CAF: A00010567: CS2M - G729 CODEC for AAL2

119.2 Purpose

In the current CS2kmt implementation, the network codec combinations for AAL2 network only include
G.711 a-law
G.711 u-law
G.711 a-law, G.711 u-law
G.711 u-law, G.711 a-law
G.726-32, G.711 a-law, G.711 u-law
G.726-32, G.711 u-law, G.711 a-law

This CAF will add six new combinations for AAL2 as customers request, which are
G.729, G.711 a-law
G.729, G.711 u-law
G.729, G.711 a-law, G.711 u-law
G.729, G.711 u-law, G.711 a-law
G.726-32, G.711 u-law
G.726-32, G.711 a-law

Note that from SN09 version the terminologies G.711 u-law, G.711 a-law are translated to PCMU, PCMA, respectively.

119.3 Problem symptoms

Previously only six codec combinations for AAL2 are allowed. If users input a combination like “G.729, G.711 a-law” and click OK button, a warning dialogue will be popped up with following message “Codec selection is invalid. Please modify it and try again. For more information about valid codec selections, please refer to the help document.

If users check the help document, they will find the following information.

AAL2	G.726-32	PCMA	PCMU
	G.726-32	PCMU	PCMA
	PCMA	PCMU	
	PCMU	PCMA	
	PCMA		
	PCMU		

The codec combination users selected is shown in field “Codec Selection”.

The help document will be

AAL2	G.726-32	PCMA	PCMU
	G.726-32	PCMU	PCMA
	PCMA	PCMU	
	PCMU	PCMA	

120: Functional description (FN): A00010617

120.1 Feature name and Feature ID

A00010617: Addition of NUERA_BTX4K and MGCP_IAD_40 Gateway certificates lines (Corrective)

120.2 Purpose

In SN09, the gateway certificate/profile “NUERA_BTX4K” is created in order to provision 4032 endpoints on TGCP large trunks gateways in SESM and support DS3 endpoint naming formats (e.g., “ds/ds3-<u1>/ds1-<u2>/[1-24]”). The certificate/profile is needed to support the Nuera BTX-4K gateway which allows 6 DS3s to be provisioned (4032 DS0s – 6x28x24). Up to now, the largest supported TGCP gateway was the Nuera BTX-21 which allowed at most 21 DS1s to be provisioned.

Additionally, the gateway certificate/profile “MGCP_IAD_40” is created in order to provision “Carrier Access Adit 600” MGCP small line gateways in SESM. The “Carrier Access Adit 600” gateway will support up to 40 endpoints (POTS lines).

120.3 Configuration

After the code changes, when associating a media gateway using SESM GUI, in the “Gateway Profile Name” pull down list, the following new profile names in addition to the existing profiles will show up as a selection choice.

- NUERA_BTX4K
- MGCP_IAD_40

The characteristics of the above gateways are listed in the following table.

GW Profile Name	GW Cate-gory	Signal Protocol	Protocol Version	Protocol Port	Service Type	Port/EP Capacity	GWC Profile No.
NUERA_BTX4K	Large	tgcp(6)	1.0	2427	Trunk	4032	60
MGCP_IAD_40	Small	MGCP(5)	1.0	2427	Line	40	49

When filling in the “Protocol Type”, “Protocol Version” and “Protocol Port” fields in the “Associate Gateway” dialog using SESM GUI, please enter in what’s specified in the above table.

When creating an OSSGATE input XML file for associating a “NUERA_BTX4K” or “MGCP_IAD_40” gateway, please reference the above table for values of the tags <mgProfileName>, <mgProtocolType>, <mgProtocolVersion>, and <mgProtocolPort>.

After the introduction of the NUERA_BTX4K certificate/profile, when adding a carrier using SESM GUI, in the “Add Carrier” dialog box, the following carrier name format can be specified in the “Carrier name:” field:

- ds/ds3-<u1>/ds1-<u2>

121: Functional Description (FN) A00010742

121.1 Feature name and Feature ID

GWC EM Enhancements to Support SIREN - A00010742

121.2 Description

In Succession, the provisioning of a Gateway Controller Card (GWC) is performed by the GWCEM/SESM and the SAM21 software components.

The SAM21 component is responsible for provisioning sufficient card data to identify the card (e.g., the IP addresses and the software load file location), and to initiate the booting of the GWC application.

The GWCEM/SESM component is responsible for provisioning all other data required for the GWC to operate as a switch (e.g., gateway data, endpoint data, alarm processing, trap processing, IPSEC data, middle boxes, timing parameters, sizing limitations, capabilities, etc.). Also included is an array of activities which include, for example, the ability to audit, monitor, patch, alarm, initiate card imaging, core provisioning and synchronization, and general health and maintenance of the GWC devices and their application processing.

For Siren, the SAM21 component is being replaced by various Siren subsystems (e.g., Config, AMF, and MTCE). In addition, the GWC application itself is being moved onto new Siren blades, and may be modified to use new interfaces within the Siren platform.

The GWCEM/SESM software will still reside on the Sun N240 SSPFS platform. The items implemented by this feature are the design changes required for the GWCEM and the SESM software to function correctly with the removal of the SAM21 component, and to address any changes required in the GWCEM to GWC interfaces made as a result of the GWC incorporation into the new Siren architecture.

This feature implements the changes required to allow the GWCEM/SESM to provide the same provisioning functionality with the newly based GWC on the Siren ATCA platform.

121.2.1 User Interface Changes

There are two user interface changes made by this activity in the GWC EM GUI.

1. In Siren configuration, the ability to bring up the SAM21 card view of the GWC card is removed, and the warm and cold swact buttons are replaced with a single ‘swact’ button. There is no change for Carrier VoIP installations.
2. In both Siren and Succesion configurations, the ‘Add GWC’ dialog box will now prompt only for GWC name and not the IP address. The IP addresses will be determined internally by the hardware management software.

There is also one change made to the OSSGate XML schema. For the add GWC (addGWCtoCS) operation, the GWC IP address will now be looked up using the GWC name (gwcUIName). Therefore, the active IP address (gwcActvIp) is no longer required by the EM software and is being made optional. Note that this parameter may still be specified, but it will be ignored.

121.3 Hardware Requirements or Dependencies

For customers continuing with the Succession product line, there are no new hardware requirements.

For customers choosing the Siren product line, there are no new hardware requirements specifically for this activity, but changes are made to the current GWC EM software to work with the new Siren product line.

121.4 Software Requirements or Dependencies

For customers continuing with the Succession product line, there are no new software requirements or dependencies.

For customers choosing the Siren product line, there are no new software requirements specifically for this activity, but changes are made to the current GWC EM software to work with the new Siren product line.

121.5 Limitations and restrictions

This feature does not address Succession to Siren migration for SESM/GWC EM.

121.6 Interactions

Not Applicable

122: Functional Description (FN) A00010880

122.1 Feature name and Feature ID

A00010880 - ABI SMU Support

122.2 Description

This activity adds support for the SMU (Subscriber Module Urban) and its subtending RCU (Remote Concentrator Urban) to the list of legacy PMs supported by the ABI program. The ABI program allows legacy host XPMs to be connected to the packet network without use of an ENET and an I/W Bridge. Instead the XPM is connected to an ABI card in the MG9K via its legacy DS-512 interface. The MG9K in turn provides connectivity to the packet network. This feature will support only the IP version MG9K.

The main customer viable changes for this activity will be the ability yo provision the EXTDS512 optional field as part of the tuple in table LTCINV for the SMU Peripheral Type. The optional field is used to identify the IP Address of the ABI Card and the Gateway Controller that the peripheral is 'hosted' off (the GWC must be datafilled in table SERVRINV prior to entering this information). A full description of the table control changes is available in the Data Schema section of this document (part of the Configuration chapter).

No RMM functionality will be supported off an ABI SMU. To support line test on the RCUs, the test configuration will be via an RMM off an ABI LTC/LGC or off an ABI SMA2.

This feature also allows the ABI SMU to be support in MG9K ESA.

122.3 Hardware Requirements or Dependencies

There are no hardware requirements for this project.

122.4 Software Requirements or Dependencies

The CM changes will be in SN10. Some core software will be submitted in tthe SN09 timeframe to make patchback to SN09 easier. The GWC changes will be in GC100. The SMU load is currently frozen. The last load was built in the XPM13 time frame out of the XPM13BC context. The XPM portion for the SMU loads will be patched back to XPM13.

122.5 Limitations and restrictions

- LDT PSAP (Line Digit Trunk Public Safety Answering Point) will not be supported off an ABI SMU.
- RMMs will not be supported off an ABI SMU.

- ABI SMU is supported in MG9K ESA but ISDN functionality will not be supported while in ESA. Currently, ISDN is not supported on any ABI XPM while in ESA.
- The SMU supports PPhones by using the D-channels provides by the ISP (ISDN Signalling Processor) and DCH (D-Channel Handler) cards. Because ISDN is not supported in MG9K ESA, the SMU will not support PPhones in MG9K ESA.
- Only the IP version of the MG9K is suported. The ATM version is not supported.

122.6 Interactions

This new code will need to interact with the existing ABI framework for link maintenance, packet connection setup, and MG9K ESA.

123: Functional Description (FN) A00011167

123.1 Feature name and Feature ID

A00011167 - MG9KEM - Central Userid and Password Support

123.2 Description

This activity enables central IEMS/ Radius authentication of the MG9K userid and password for EM SFTP access to the MG9K. The userid and password will be configured on a per MG9K Element Manager (EM) basis in addition to an NE basis. If Radius is not available when the EM communicates with the MG9K, the NE-level userid and password will be used for authentication instead of the EM-level userid and password. If the Radius is available, there will not be an attempt to authenticate using the NE-level userid and password.

The same userid and password must be configured on the EM and Radius. At the EM, the EM-level userid and password will be configured using a new GUI that is accessed at the subnet level. A warning message will inform the user that the EM-level userid and password will be used instead of the NE-level userid and password. The EM-level userid and password will be stored in the EM Oracle database.

123.3 Hardware Requirements or Dependencies

None.

123.4 Software Requirements or Dependencies

This feature will be delivered in the SN09 software release.

123.5 Limitations and restrictions

For the Radius server authentication to work correctly, when the central userid and password is changed at the Radius server, the EM level userid and password must be changed to match the Radius central userid and password. Note that if an NE-level userid and password happens to match the Radius userid and password, the authentication will work if the Radius server is not available.

123.6 Interactions

None

124: Functional Description (FN) A00011281

124.1 Feature name and Feature ID

A00011281 - MS2000 IPSec Configuration via IEMS

124.2 Description

This feature adds IPSec and IKE configuration capabilities to the MS2000 node configuration tool introduced in SN08. This will allow the craftsperson to enable IPSec for secure messaging between the IEMS and MS2000 as well as configure the IPSec and IKE parameters necessary for the MS2000 to securely send and receive messages to and from the GWC.

See the configuration section for full details on the new functionality.

124.3 Hardware Requirements or Dependencies

No specific requirements beyond what is necessary to support the SN09 software.

124.4 Software Requirements or Dependencies

SN09 IEMS and SSPFS.

SN08 or later MS2000 (?)

124.5 Limitations and restrictions

The MS2000 node does not support in-service updates to IPSec configuration data. Any changes to the IPSec data requires a reset of the MS2000 node.

124.6 Interactions

This feature extends the MS2000 configuration tool introduced in SN08 on the IEMS. It adds an additional tab to the tool that allows for the configuration of IPSec.

125: Functional Description (FN) A00011533

125.1 Feature name and Feature ID

A00011533: Support of SIP DID Trunks on Session Server Trunking

125.2 Description

This feature provides IETF compliant SIP and SIP-T interface for interworking between switches and/or any other third party SIP servers.

Session Server Trunking (SSt) will replace VRDN to provide SIP functionality/interface. This feature can be sub-divided into following components:-

- Preserve existing SIP-T functionality provided by VRDN
- Support MTX DID trunk type on the SST
- Provide enhanced ANSI ISUP parameter mapping to SIP to support SIP interface to remote switch and/or third party SIP servers.
- Support Session Timer (RFC 4028)

Both SIP and SIP-T are supported by SST. Provisioning via web GUI allows to configure a remote server to support either SIP or SIP-T. Note that simultaneous SIP and SIP-T interface to a remote server is not supported.

There are no design changes anticipated for supporting MTX DID trunks over SIP-T interface. Its an integration test activity.

All development work will be done in SN09+ stream and patched back to SN09.

SIP interface requires mapping of ISUP parameters in MTX DID trunks into SIP headers and parameters. Currently SSt supports IT and IBNT2 trunks. This feature builds on top of existing functionality in SST to support MTX DID specific parameters and features.

The following table lists the ISUP parameters and their mappings into SIP and vice-versa. The SIP parameters in **bold** are either impacted or introduced by this feature.

Table 1: ISUP to SIP to ISUP mappings

Table 1: ISUP to SIP to ISUP mappings

ISUP Param	ISUP to SIP		SIP to ISUP		Comments
	ISUP	SIP	SIP	ISUP	
UUI	Info	**UUI Payload**	**UUI Payload**	Info	New payload type. **Nortel Prop.**
Geodetic Location	Geodetic location	**application/location**	**application/cpim-pidf+xml**	Geodetic location	New payload type. **Nortel Prop.**
Precedence	Level	**Precedence:**	**Precedence:**	Level	New header Precedence value **Nortel Prop.**
	LFB	**lfb=**	**lfb=**	LFB	Param in new header Precedence **Nortel Prop.**
	NetID	**netid=**	**netid=**	NetID	Param in new header Precedence **Nortel Prop.**
	MLPP_SD	**mlpp=**	**mlpp=**	MLPP_SD	Param in new header Precedence **Nortel Prop.**
Carrier Selection	carrier selection	**csel=**	**csel=**	carrier selection	User info of Request URI. **Nortel Prop**.

125.2.1 Satellite Indicator

A new parameter, satellite, will be created and added to the Request URI. The parameter will be defined as follows.

satellite = satellite-tag "=" number-of-satellite

satellite-tag = "sat-hops"

number-of-satellite = 0|1|2|3

Example:

```
INVITE sip:6137222000@47.174.73.240:5060;sat-hops=2 SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010@47.142.211.17;user=phone>
```

125.2.2 Calling Party Category

A new parameter, cpc, will be created in the SIP URI and added to the PA-Id header and From header user information. CPC User info present in PA-ID header overrides user info CPC if present in From header. The parameter will be defined as follows.

cpc = cpc-tag "=" cpc-value

cpc-tag = "cpc"

cpc-value = string

string = { “unknown”|
“op-french” |
“op-english” |
“op-german” |
“ op-russian” |
“op-spanish” |
“cpc-[6, 7, 8]” |
“op-national” |
“ordinary” |
“priority” |
“data” |
“test” |
“non-voice” |
“payphone”|
“voice-information” |
“executive-intrusion" |
“cpc-[18, ..., 21]” |

"mobile" |
"cpc-[23, 24, 25]" |
"mexico-payphone" |
"cpc-[27, ..., 160]" |
"attendant" |
"ac-prec-2" |
"ac-prec-3" |
"ac-prec-4" |
"ac-prec-5" |
"cpc-[166, ..., 223]" |
"emergency" |
"cpc-225" |
"nsep" |
"cpc-[227, ..., 249]" |
"prec-2" |
"prec-3" |
"prec-4" |
"prec-5" |
"cpc-[254, 255]"

}

Example:

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010;cpc=payphone@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-
144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010;cpc=payphone@47.142.211.17;user=phone>
```

125.2.3 Charge Number

Charge Number is an optional parameter in IAM message. This parameter will be mapped into a new SIP header.

```
charge = "charge" HCOLON "<" addr-spec ">" ";" noa
noa = "noa" EQUAL  1*DIGIT [1*DIGIT] [1*DIGIT]
```

Table 2: Charge Number NOA Digit Values

Charge NOA DIGIT(s)	GR-317 Definition/Interpretation
0	Unknown/Spare
1	ANI of calling party, Subscriber Number
2	ANI not available not provided
3	ANI of calling party, National Number
5	ANI of called party, Subscriber Number
6	ANI of called party Not Included
7	ANI of called party, National Number
120	Charge Number Operator Collected

An example IAM message:

```
OPTIONAL PART:        CHARGE NUMBER:
                         NATURE_OF_ADDR_IND : CLGP_ANI_SUBSCRIBER_NUMBER
                         ODD_IND :            ODD
                         NUMBERING_PLAN :      ISDN_TELEPHONY_NUM_PLAN
                         ADDRESS : 1234567
```

The resulting SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060;SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010@47.142.211.17;user=phone>
Contact: <sip:47.174.73.240:5060>
Charge:<sip:1234567>;noa=1
```

125.2.4 Originating Line Information (OLI)

OLI may be present in the ISUP IAM message. OLI information is used to identify special calls(hotel/prison etc) and can be used to identify location services available in 911 scenarios.

OLI will be carried in a new parameter added to the PAID header and From header user information. OLI User Info arriving in PAID header overrides OLI user info arriving in From header.

```
oli = "oli" EQUAL 1*DIGIT [1*DIGIT][1*DIGIT]
```

Table 3: OLI Digit Values

OLI DIGIT(s)	GR-317 Definition/Interpretation
0	Normal ANI/No Special Treatment
1	Normal ONI(multiparty)
2	ANI Failure
3	Service Analyzed ANI
4	Service Analyzed ONI
5	Service Analyzed ANI Failure
6	Hotel(without room ID)
7	Coinless Payphone
8	Interlata Restricted
10	Test Call
20	AIOD Listed DN Sent
23	Coin or Non Coin
24	800 Call
25	800 Payphone Call
27	Coin Phone
29	Prison Phone
61	Cellular Services Type 1

Table 3: OLI Digit Values

OLI DIGIT(s)	GR-317 Definition/Interpretation
62	Cellular Services Type 2
63	Cellular Services Type 3
68	Hotel Interlata Restricted
70	Private Pay Phone
78	Coinless Interlata Restricted

Example SIP message(oli is cellular services type 1):

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010;cpc=payphone; oli=61@47.174.73.240:5060>;tag=f-13c4-419b7608-
137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010;cpc=payphone; oli=61@47.142.211.17;user=phone>
```

125.2.5 Redirection Parameters

Redirection information is carried in the new header introduced by this feature. History-Info is the header proposed by an IETF draft and is most likely to be converted into a RFC. Current implementation which uses Remote-Party-ID and Diversion headers are still available. Customers have a choice on which method to use per remote server via provisioning choices on the GUI.

Below is an example message to illustrate how the ISUP IAM redirecting params are mapped into a SIP message.

The scenario described here is:

- A calls B
- B is busy and has CFB to C.
- C does not answer and has Call Forward No Answer to D
- The C to D call leg is over SIP.

A = 6137222010; B = 6137222009; C = 6137222015; D = 6137222000

The relevant parts of the IAM look like this:

```
CALLING PARTY :
    EVEN_ODD_IND:                      EVEN_NUM_NIBBLES
    NATURE_OF_ADD :                    NATIONAL_SIG_NUMBER
    ADDR_PRES_RESTRICTED_IND           PRESENTATION_ALLOWED
    NUMBERING_PLAN :                   ISDN_TELEPHONY_NUM_PLAN
    SCREENING_IND  :                   NOT USED
    ADDRESS_INFORMATION = 6137222010
REDIRECTION INDICATOR :
    REDIR_IND :                         REDIR_CALL_FORWARDED
    CFD_INDICATOR :                     TRUE
    ORIG_REDIR_REASON :                 REDIR_USER_BUSY
    REDIR_COUNTER :                     2
    REDIR_REASON :                      REDIR_NO_REPLY
 ORIGINAL CALLED NUMBER :
     EVEN_ODD_IND:                      EVEN_NUM_NIBBLES
     NATURE_OF_ADD :                    UNIQUE_NATIONAL_SIG_NUMBER
     ADDR_PRES_RESTRICTED_IND :         PRESENTATION_RESTRICTED
     NUMBERING_PLAN :                   ISDN_TELEPHONY_NUM_PLAN
     SCREENING_IND  :                   USER_PROVIDED_NOT_SCREEN
     ADDRESS_INFORMATION = 6137222009
   REDIRECTING NUMBER
      EVEN_ODD_IND:                     EVEN_NUM_NIBBLES
      NATURE_OF_ADD :                   NATIONAL_SIG_NUMBER
      ADDR_PRES_RESTRICTED_IND :        PRESENTATION_ALLOWED
      NUMBERING_PLAN :                  ISDN_TELEPHONY_NUM_PLAN
      SCREENING_IND  :                  NOT USED
      ADDRESS_INFORMATION = 6137222015
```

The resulting SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6

125.2.6 CIP/TNS Parameters

Carrier Identification Parameter(CIP) and Transit Network Selection(TNS) information are carried in new parameters introduced by this feature to the Request-URI Header. Below are examples of CIP transport and TNS transport.

The CIP and TNS are valid optional parameters in the ISUP IAM message

cip = 4*DIGIT

cic= 4*DIGIT

netid= 1*DIGIT

sc = 1*DIGIT [1*DIGIT]

Table 4: CIP/TNS Netid DIGIT Values

Netid DIGIT	Q.763 Interpretation
0	CCITT /ITU-T Standard
2	National Network

An example IAM message optional part transporting CIP:

```
OPTIONAL PART:      CARRIER IDENTIFICATION PARAMETER :
                    NETWORK_ID_PLAN :        FOUR_DIGIT_CIC
                    TYPE_OF_NETWORK_ID :     CCITT_STANDARDIZED
                    CARRIER_IDENTIFICATION_CODE : 4712
```

The resulting SIP message:

125.2.7 Jurisdiction Information Parameter

Jurisdiction Information Parameter is a six digits optional parameter in the IAM message representing the geographic location for the call origination.

A new parameter, jip, will be created and added to the PA-Id and thr From header user information. The parameter will be defined as follows. If present, JIP user info arriving in PAID header overrides JIP user info arriving in From header.

Jurisdiction Information Parameter= jip-tag "=" six-digit-string

jip-tag = "jip"

six-digit-string = 6[0|1|2|3|4|5|6|7|8|9]

Example SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010;cpc=payphone;oli=61;jip=919991@47.174.73.240:5060>;tag=f-13c4-

CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010;cpc=payphone;oli=61;jip=919991@47.142.211.17;user=phone>
```

125.2.8 Generic Digits

Generic Digits is an optional parameter in IAM message. This parameter will be mapped into a new SIP header.

```
Gen-Digit = "Generic-Digits" HCOLON addr ";" type
type = "type" EQUAL  ("authcode" |
                      "priv-net-trav-classmark"|
                      "clli-admin" |
                      "ani-index" |
                      "member-range-info" |
                      "uss-redir-info" |
                      "term-swid"
                      "call-id" |
                      "wireless-emergency"|
                      "access-node-orig-info" |
                      "osid-plus-otg" |
                      "imt-info" |
                      "hotel-room" |
                      "hotel-guest-name"
                      "division-id" |
                      "trunk-id"|
                      "ooy" |
                      "transport-info" |
                      "super-gd" |
                      "fallback-context-block" |
                      "keyed-fallback-digits"
                      "e911tandem-prefix" |
                      "ind-con"|
                      "correlation-id" )
```

An example IAM message:

```
OPTIONAL PART:        Generic Digits:
                         GENERIC_DIGITS_TYPE : E911TANDEM_PREFIX
                         ENCODING_SCHEME :     BCD_ODD
                         DIGITS :              12345
```

The resulting SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060;SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445

Gen-Digit:12345;type=e911tandem-prefix
```

125.2.9 User to User Indicator/Information (UUI)

UUI can be received in IAM, ACM or ANM. Since User to User information can be large, it does not make sense to make it a SIP header or parameter. Instead UUI will be tunnelled as a payload using a newly defined MIME type

content-type: application/UUI

Example SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445

Contact: <sip:47.174.73.240:5060>
Content-Type: application/UUI
Content-Length: 40
<payload>
```

125.2.10 Geodetic Location

This is an optional parameter in IAM and is used in the network to carry cell/ sector ID for 911 calls. Draft draft-ietf-sip-loaction-conveyance-00.txt recommends that location information be carried as a payload in SIP message Geo Location will be tunnelled as a payload using a newly defined MIME type

content-type: application/cpim-pidf+xml

Example SIP message:

```
INVITE sip:6137222000@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010@47.142.211.17;user=phone>
Contact: <sip:47.174.73.240:5060>
Content-Type: application/cpim-pidf+xml
Content-Length: 40
<payload>
```

125.2.11 Precedence

This is an optional parameter in IAM and is used in the network to carry precedence calls.

A new proprietary header called Precedence with Precedence level, LFB, and MLPP_SD will be created

precedence : Level ; LBF ; MLPP_SD ; NETWORK_ID

Level = “precedence” EQUAL (“FLASH_OVERRIDE” |
“FLASH “ |
“PRIORITY” |
“ROUTINE”)

LFB = “lfb” EQUAL (“ALLOWED” |
“RESERVED” |
“NOT_ALLOWED”)
MLPP_SD = (MLPP_SD_1, MLPP_SD_2, MLPP_SD_3)

MLPP_SD_1 = byte

MLPP_SD_2 = byte

MLPP_SD_3 = byte

NET_ID = (NET_ID_2, NET_ID_1, NET_ID_4, NET_ID_3)

NET_ID_1 = byte

NET_ID_2 = byte

NET_ID_3 = byte

NET_ID_4 = byte

125.2.12 Carrier Selection

Carrier Selection is an optional parameter in the IAM message.

A new parameter, csel, will be created and added to user info of the Request URI The parameter will be defined as follows.

csel-tag = "csel"

csel-string = [“noind”, “sub”, “subdialed”, ”subnoind”, ”dialed”]

Example SIP message:

```
INVITE sip:6137222000;csel=sub@47.174.73.240:5060 SIP/2.0
From: <sip:6137222010@47.174.73.240:5060>;tag=f-13c4-419b7608-137445-144454f6
To: <sip:6137222000@47.174.73.240:5060>
Call-ID: 41840594f049ae2f13c4419b760813744521850ff89430478-0125-7168
CSeq: 1 INVITE
User-agent: CS2000/NGSS/9.0
X-Nortel-Profile: DEFAULT
```

```
Max-Forwards: 70
Supported: 100rel
Allow: ACK,BYE,CANCEL,INVITE,OPTIONS,INFO,SUBSCRIBE,REFER,NOTIFY, PRACK
Via: SIP/2.0/UDP SP2KDON:5060;maddr=47.174.73.240;branch=z9hG4bK-419b7608-137445
P-Asserted-Identity: <sip:6137222010@47.142.211.17;user=phone>
```

125.2.13 Session Timer

The Session Timer extension (RFC4028) enables SIP servers and endpoints to know if an endpoint is no longer in a session (for example in case of a crash) and to limit the duration of a session. An endpoint that has the Session Timer extension activated will send periodic keep-alive messages to notify that it is active or to extend the duration of the session.

RFC 4028 Session Timers in the Session Initiation Protocol (SIP) defines two new headers - Session-Expires and Min-SE and a new response code of 422. The Session-Expires header conveys the lifetime of the session, the Min-SE header conveys the minimum value for the Session Timer, and the 422 response code indicates that the Session Timer duration is too small. The Session-Expires/session timer value allowed to provisioned on SST GUI is 5-30 minutes.

The Session Timer extension enables determining the duration time of a call. A Session-Expires header included in the 2xx response of an initial INVITE determines the session duration. Periodic refresh enables extending the duration of the call and allows both User Agents (UAs) and proxies to determine if the SIP session is still active. The refresh of a SIP session is done through a re-INVITE or UPDATE. UPDATE method is preferred if remote sip server supports UPDATE.

The Session-Expires header in the 2xx response also indicates which side will be the refresher, in other words, which side will be responsible for generating the refresh request. The refresher can be UAC or UAS. The refresher should be generated a refresh request (using re-INVITE or UPDATE) before the session expires, normally at half of the Session-Expires value. If no refresh request is sent or received before the session expires, or if the refresh request is rejected, both parties will send BYE.

To enable Session Timer on Remote Sip Server, following steps need to be followed:

- SIP Gateway, Config Data, supportedExtensionList, change from “100rel” to “100rel, timer”. This change requires callp restart to take effect. Steps required to update config parameters which can not be changed dynamically need to follow here.
- SIP Gateway, Remote SIP Server, Advanced SIP Options, Long Call Audit Mechanism, choose Session Timer, default is INFO

- SIP Gateway, Remote SIP Server, Advanced SIP Options, choose timer value between 5-30 minutes, default is 20 minutes

125.2.14 Provisioning

The new functionality introduced by this feature is by default turned off when a new remote SIP server is provisioned. To enable specific or all mappings, a craftpserson can select ‘Advanced SIP Options’ section and enable the capabilities.

Advance SIP options feature are divided into following categories:
- Methods Supported
- SIP Headers Supported
- URI Parameters Supported
- General Configuration

Methods Supported is not impacted by this feature this feature.

SIP Headers Supported
Craftsperson can use this section to enable/disable specific SIP headers a remote SIP server can support. The choices relevant to this features are:
- History Info
- Generic Digits
- Charge Number
- Geodetic Location
- Precedence

URI Parameters Supported
Craftsperson can use this section to enable/disable specific parameters in the URI. The choices relevant to this feature are:
- Satellite Indicator
- Calling Party Category (CPC)
- Originating Line Information (OLI)
- CIP
- JIP

General Configuration
Craftsperson can use this section to enable/disable other enhanced SIP options. The choices relevant to this feature are:
- UUI support
- Automatic Congestion Level
- Long Call Audit Mechanism
- Session Timer Value

In addition to Advance SIP options, craftperson has a choice to provision Advanced PSTN Transparency options for a remote SIP server. The only

choice added by this feature is ‘National Circuit Code’ which has default value of eight and can be modified by the craftsperson.

125.2.15 SIP/SIP-T Interworking Support for North America

The following table provides the SIP/SIP-T interworking support for North America.

Table 5: North American SIP/SIP-T interworking

	PMTX 13	PMTX 14 VRDN	PMTX 14 NGSS	CS2K NGSS	CS2K VRDN	PGMSC 13	PGMSC 14 VRDN	PGMSC 14 NGSS
PMTX13	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PMTX14 VRDN	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PMTX14 NGSS	SIP-T	SIP-T	SIP or SIP-T	No Support	No Support	SIP-T	SIP-T	SIP or SIP-T
CS2K NGSS	No Support	No Support	No Support	SIP or SIP-T	SIP-T	No Support	No Support	No Support
CS2K VRDN	No Support	No Support	No Support	SIP-T	SIP-T	No Support	No Support	No Support
PGMSC 13	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PGMSC 14 VRDN	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PGMSC 14 NGSS	SIP-T	SIP-T	SIP or SIP-T	No Support	No Support	SIP-T	SIP-T	SIP or SIP-T

- VRDN to SST interworking will support only SIP-T between two packet switches (Serving or Gateway).
- SST to SST interworking will support both SIP or SIP-T between two packet switches (Serving or Gateway).

- At this time no testing has been done to verify support of SIP/SIP-T between packet and CS2k irrespective of SST or VRDN. Test setup and testing is not in the scope of this feature and needs a test activity.

125.2.16SIP/SIP-T Interworking Support for International Market

The following table provides the SIP/SIP-T interworking support for International variants. In SN09U only CCITT Brazil MTX_BLUE variant is supported

Table 6: International (Brazil) SIP/SIP-T interworking

	PMTX 13	PMTX 14 VRDN	PMTX 14 NGSS	CS2K NGSS	CS2K VRDN	PGMSC 13	PGMSC 14 VRDN	PGMSC 14 NGSS
PMTX13	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PMTX14 VRDN	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PMTX14 NGSS	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
CS2K NGSS	No Support	No Support	No Support	SIP-T	SIP-T	No Support	No Support	No Support
CS2K VRDN	No Support	No Support	No Support	SIP-T	SIP-T	No Support	No Support	No Support
PGMSC 13	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PGMSC 14 VRDN	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T
PGMSC 14 NGSS	SIP-T	SIP-T	SIP-T	No Support	No Support	SIP-T	SIP-T	SIP-T

- For international markets, only SIP-T is supported between two packet switches (Serving or Gateway) irrespective of SST or VRDN.qqqq

- At this time no testing has been done to verify support of SIP/SIP-T between packet and CS2k irrespective of SST or VRDN. Test setup and testing is not in the scope of this feature and needs a test activity.

125.3 Hardware Requirements or Dependencies

None

125.4 Software Requirements or Dependencies

None

125.5 Limitations and restrictions

- Since most of the new SIP headers and parameters introduced by this feature are not part of any SIP RFC or draft (except History-Info), the enhanced SIP mapping provided by this feature will only work with between two Nortel CS2Ks/PMSCs.
- Simultaneous SIP and SIP-T interface to a remote server is not supported.
- This feature supports only ANSI ISUP. SIP interface for international variants (e.g Brazil ISUP) is not supported.
- This feature functionality will be delivered as a patch(s) in SN09.

125.6 Interactions

None

125.7 Glossary

Term	Description
NGSS	Next Generation Session Server
SIP	Session Initiation Protocol
RFC	Request For Comment
OLI	Originating Line Information
JIP	Juridiction Information Parameter
CIP	Circuit Identification Parameter

126: Functional Description (FN) A00011740

126.1 Feature name and Feature ID

A00011740: Packet Cable Multimedia for CS2K

126.2 Description

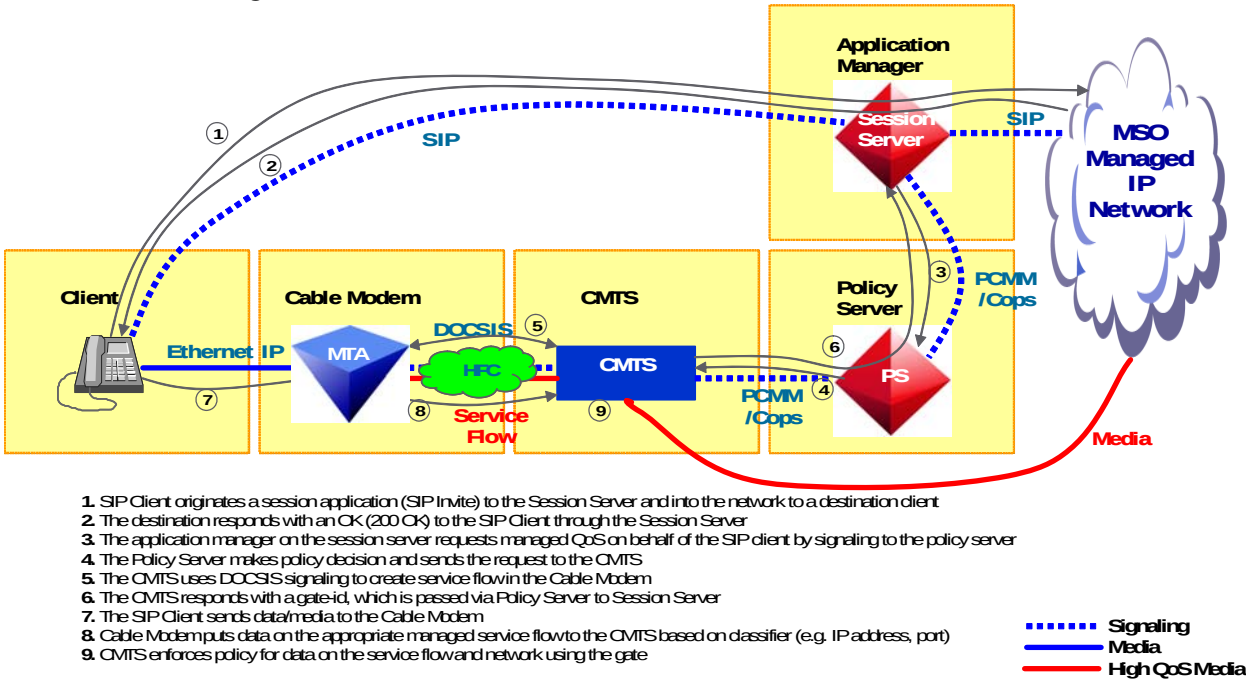
126.2.1 Functional Overview

PacketCable Multimedia is an architecture developed by CableLabs to enable MultiService Operating Companies to deliver Quality of Service enabled multimedia services over DOCSIS networks. PacketCable Multimedia extends the Dynamic Quality of Service architecture developed as part of PacketCable 1.X to allow Application Managers in the MSO network to request and obtain Quality of Service treatment for multimedia traffic flows on behalf of an end user.

This service enhances the CS2000 SIP Lines solution to take advantage of the PacketCable Multimedia mechanisms to provide QoS for voice and video sessions established over an MSO DOCSIS network. The PCMM signaling implementation is compliant with PacketCable specification PKT-SP-MM-I02-040930 (refer to section 126.8 on page 1219 for a detailed compliance matrix).

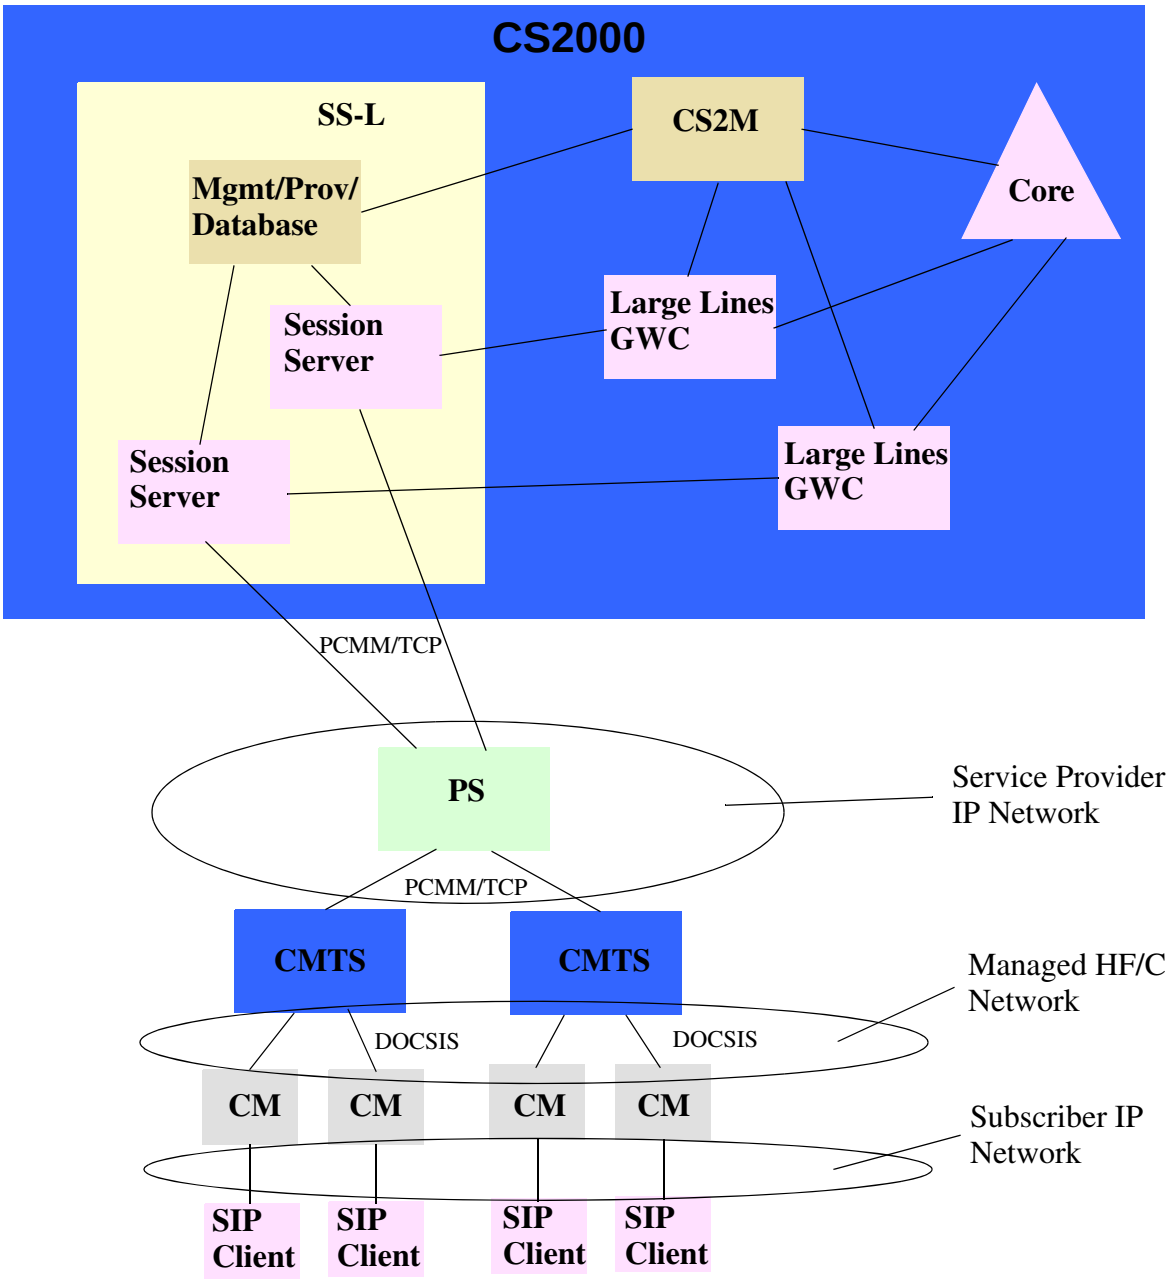
The following diagram illustrates a high level call flow for a PacketCable Multimedia (PCMM) SIP call in the CS2000.

Figure 1 PCMM SIP Call Flow



The following diagram illustrates a typical cable network topology for a SIP lines deployment. Both MCS and CS2K are shown.

Figure 2 PCMM Network Diagram



The diagram points out three networks: the service provider IP network, the HF/C (hybrid fiber/coax) network and the subscriber IP network. The network that is not explicitly shown is the call server IP network by which the CS2K and MCS network elements communicate.

The HF/C network is the focal point of PCMM since that is where we are managing QoS. For media stream network connectivity between a SIP client

and another endpoint, DIFFSERV is used for QoS outside of the HF/C network.

The subscriber IP network may be behind a NAT. SIP clients can be SIP phones or SIP soft-clients such as the Nortel's MCS Multimedia PC client.

The following sections describe how to setup PCMM, how to determine if PCMM is working correctly, and how to alter the PCMM configuration after it is up and running.

126.2.2 Setting up PCMM

In order to setup the PCMM service the following high level steps must be carried out in order. Detailed instructions for each step can be found by following the links.

1. Enable the PCMM Service Key (see section 126.2.5 on page 1180)
2. Add a policy server IP address (see section 126.2.6 on page 1181)
3. Add a policy server (see section 126.2.7 on page 1182)
4. Configure the policy server AMIDs for each session manager (see section 126.2.8 on page 1185)
5. Assign Diffserv value for subscriber (see section 126.2.9 on page 1188)
6. Assign PCMM capability to subscribers (see section 126.2.10 on page 1191)

126.2.3 Verifying that PCMM is working

Once you have gone through the steps outlined in section 126.2.2 on page 1180, you can do the following to verify that PCMM is working as expected.

1. Check for PCMM alarms (see section 126.2.11 on page 1197)
2. View PCMM operational measurements (see section 126.2.12 on page 1201)

126.2.4 Altering PCMM configuration

If you need to alter your PCMM configuration or provisioning, please see the following sections.

- Changing PCMM configuration (see section 126.2.13 on page 1207)
- Removing PCMM service from a subscriber (see section 126.2.14 on page 1208)
- Deleting a policy server (see section 126.2.15 on page 1209)

126.2.5 Enabling the PCMM Key

The PCMM service is key coded. To use the PCMM functionality, the PCMM key must be enabled, and part of your systems license key.

The PCMM key within the license can be generated as enabled, disabled, or not present. If the key is not present then the service is disabled.

Key codes within a license key can be added or upgraded, but keys can not be removed. Once a license is added to a system with PCMM enabled, The PCMM key can not be disabled.

The generation of the license key with the PCMM key code is done using the Nortel KRS (Key Registry System).

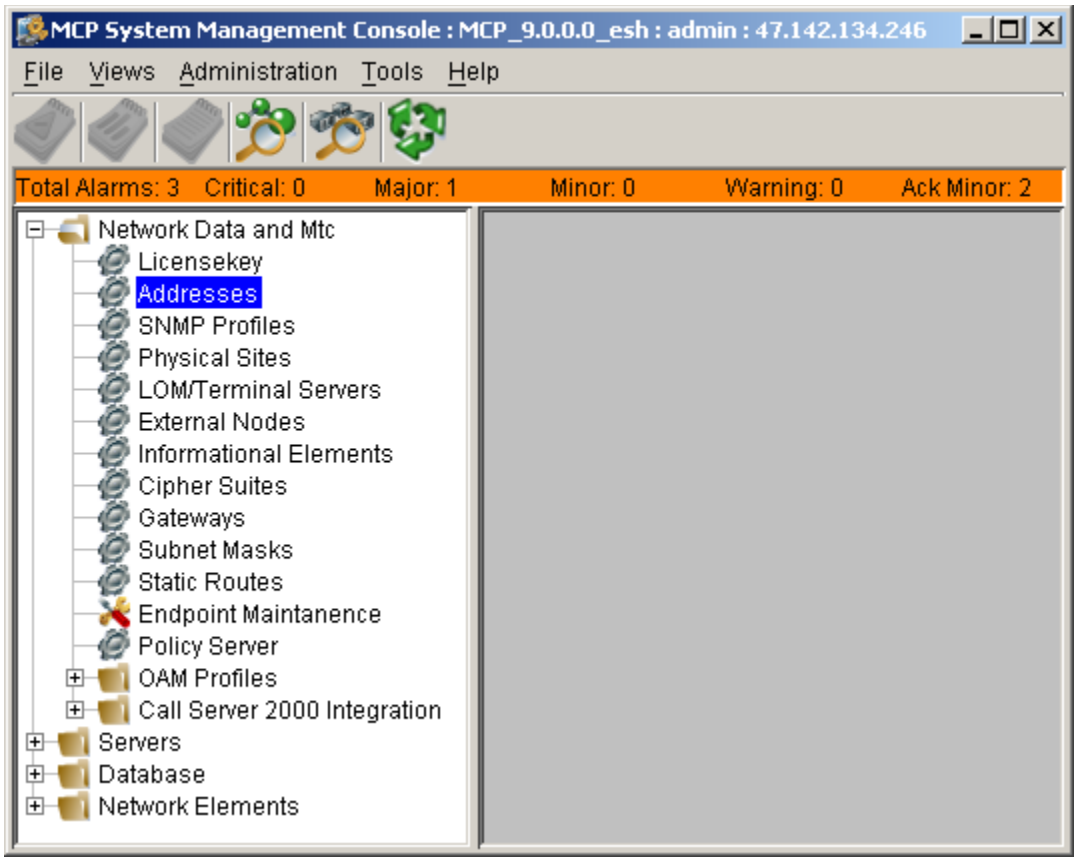
The addition of a system license key is covered as part of the installation and commissioning process.

126.2.6 Associating a Logical Name to a Policy Server IP address

To configure a policy server IP address and associate the address with a name that will be used in subsequent references to the address:

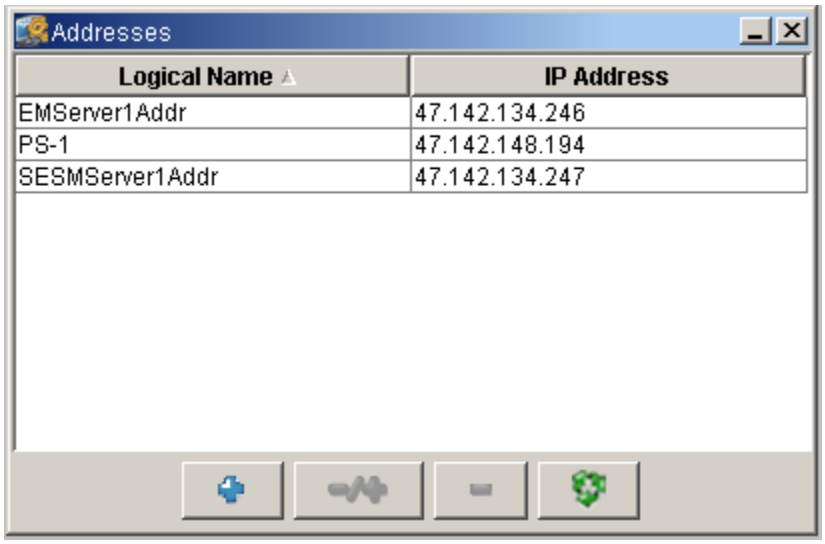
- From the MCP System Management Console expand the “Network Data and Mtc” item

Figure 3 MCP System Management Console for Addresses



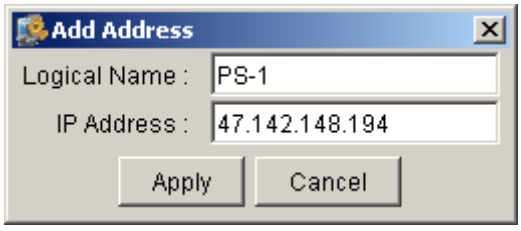
- Click the ‘Addresses’ icon, the ‘Addresses’ window will appear

Figure 4 Addresses Dialogue



- Select '+'and provide the PS address logical name and IP address in the form x.x.x.x

Figure 5 Add Address



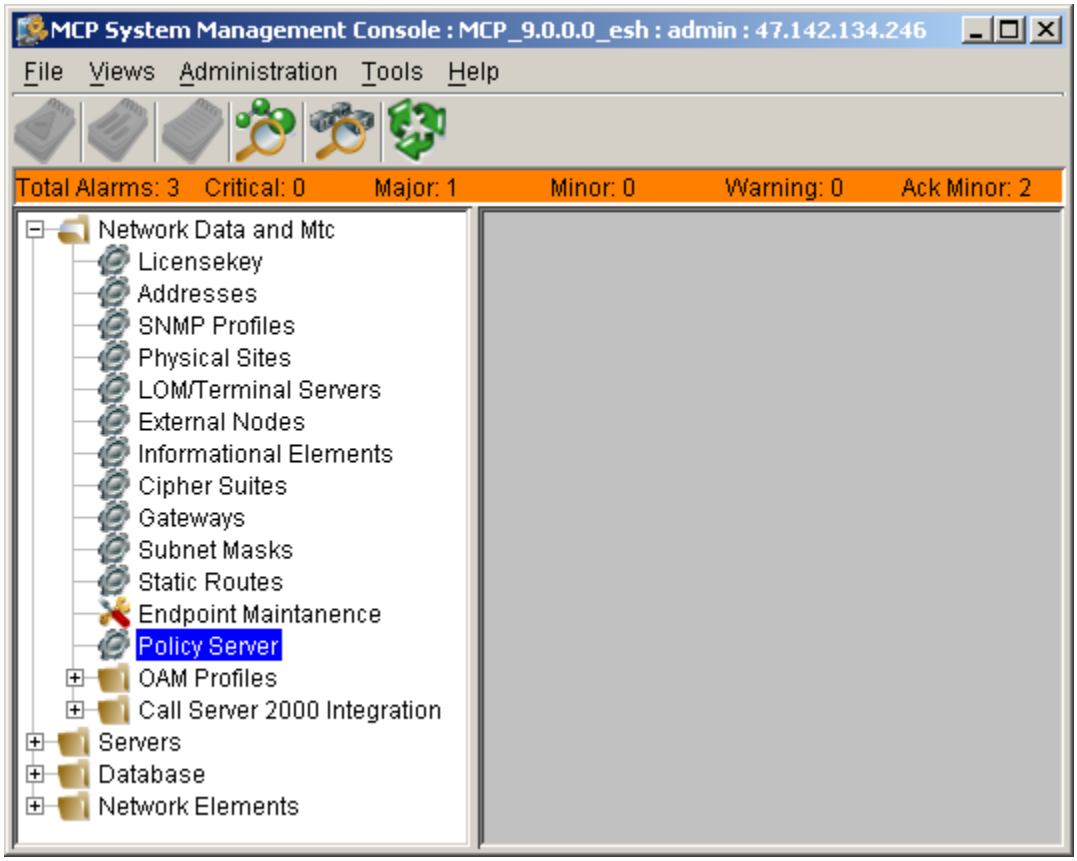
Now the logical name ("PS-1" in this example) will appear as a choice anywhere you need to enter an IP address.

126.2.7 Adding a Policy Server

To add a policy server:

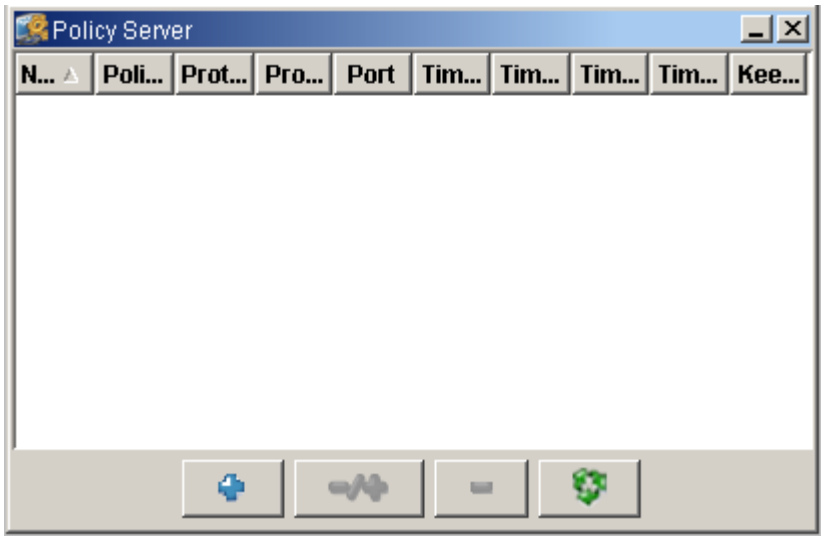
- On the MCP System Management Console GUI expand the "Network Data and Mtc" tree

Figure 6 System Management Console for Policy Server



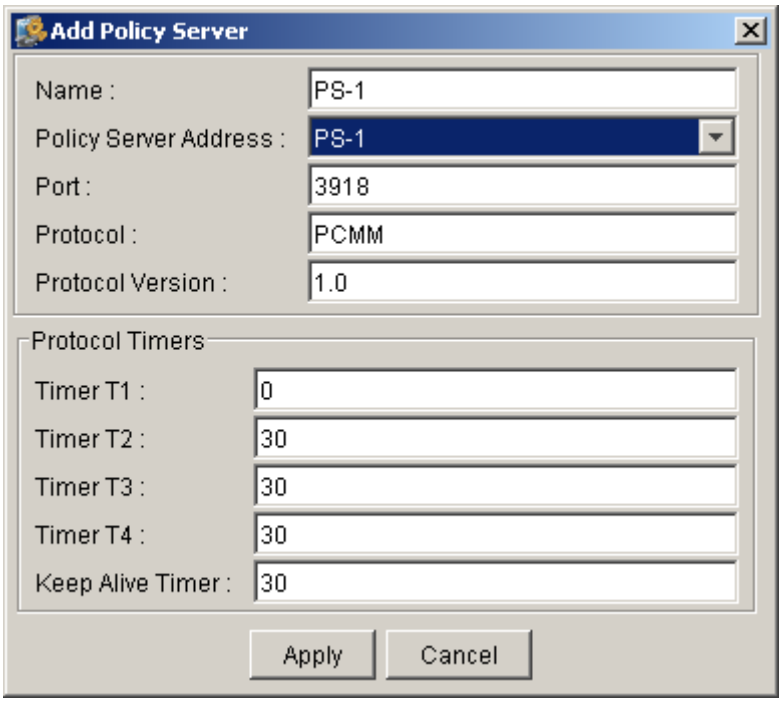
- Click “Policy Server” and a Policy Server window will appear showing the existing policy servers (if any)

Figure 7 Policy Server Dialogue



- Select the '+' icon and a new window appears. Enter the following fields:

Figure 8 Add Policy Server



a. **Name**: customer defined string up to 16 characters

b. **Policy Server Address**: select the logical address to assign from the pull down list which was configured under the 'Addresses' icon (see section 126.2.6 on page 1181). This is the address that the policy server will listen on for PCMM signaling.

c. **Port:** this is the port number the policy server will listen on for PCMM signaling. It must be and integer value from 1 to 65,535. The IANA well-known port for PCMM is 3918, so unless a different port is required by the policy server 3918 should be used.

d. **PCMM Protocol**: the PCMM signalling protocol used by the Policy Server. This should be set to the string "PCMM".

e. **Protocol Version -** the pulldown menu shows PCMM protocol versions supported by the CS2000. Choose the highest protocol version that you want the CS2000 to negotiate to for the policy server being configured. For example, if the policy server and the CS2000 both support versions 1.0 and 2.0, but you wish to continue using version 1.0, you can select 1.0 for this field.

f. **Timer T1:** timer maintained by the CMTS to determine the time in seconds that a gate can be in the 'authorized state'. A value of zero (the default) indicates that CMTS should use its own provisioned value.

The suggested range for this timer (if not zero) is between 5 and 180 seconds.

g. **Timer T2:** timer maintained by the CMTS to determine the time in seconds that excess reserved bandwidth must be held by CMTS. A value of zero disables this timer. The default value is 30 seconds. The suggested range for this timer (if not zero) is between 5 and 180 seconds.

h. **Timer T3:** timer maintained by the CMTS to determine the time in seconds that the service flow can be idle (no packets flowing) before being reported by CMTS. A value of zero disables service flow activity monitoring. **Nortel strongly recommends against disabling this timer as this can lead to hung resources in the CMTS**. The default value is 30 seconds. The allowed range for this timer is between 10 and 300 seconds.

i. **Timer T4:** timer maintained by the CMTS to determine the time in seconds that a gate can remain in the 'committed-recovery state' (due to T3 expiration). **Nortel strongly recommends against a T4 value less than 10 seconds**. The default value is 30 seconds. The allowed range for this timer is between 10 and 300 seconds.

j. **Keep Alive Timer:** this is the PCMM keep alive timer which is used to determine if the PS connection is healthy. The default value is 30 seconds. The allowed range for this timer is between 10 and 180 seconds. Keep-alive messaging cannot be disabled.

Once these fields are entered, click "Apply" and the PS will be configured.

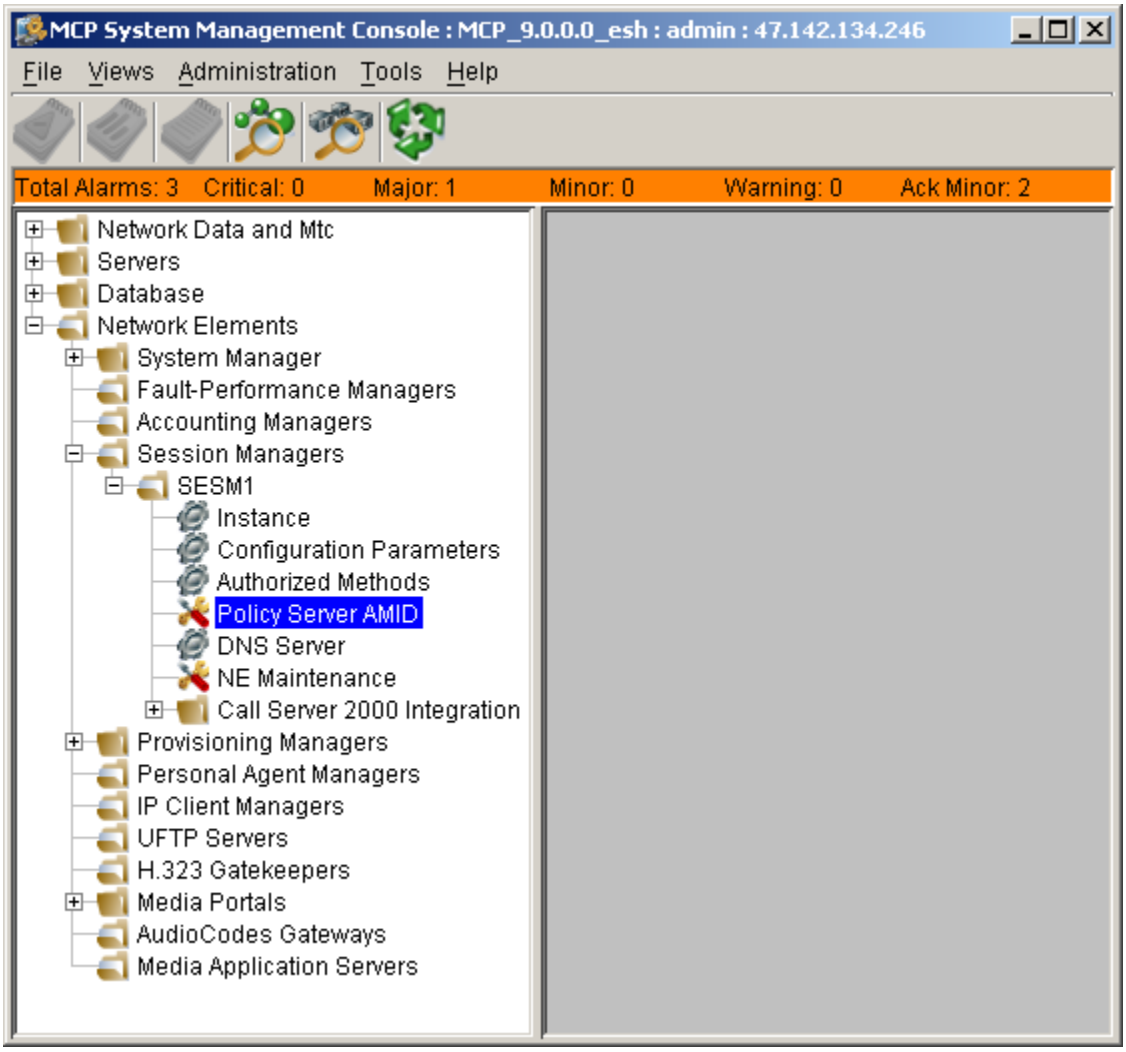
126.2.8 Configuring AMIDs for a Policy Server

For each PCMM signaling connection to a policy server, a set of application manager IDs must be configured. These AMIDs may be used by the policy server to keep track of application manager connections or may even be used to give the policy server an indication of the type of service being requested (audio or video).

In the MCS system, each active session manager has a connection to the policy server. Each active session manager must therefore have a set of AMIDs configured against the policy server. Here are the steps to set up AMIDs for a session manager. ***These steps must be repeated for each active session manager in the system.*** You need not configure AMIDs for redundant session managers.

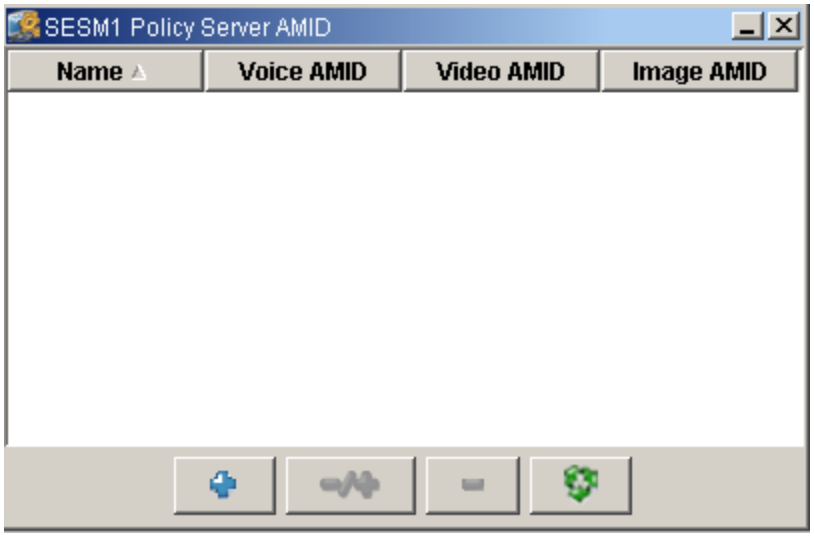
- From the MCP System Management Console, expand the Network Elements, Session Managers and then an instance of a session manager (SESM1 in this example).

Figure 9 System Management Console for AMIDs



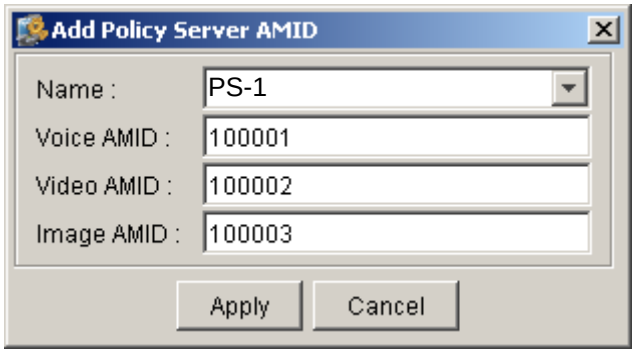
- When you click on “Policy Server AMID”, a window appears showing the configured policy servers. Select a policy server and a window will appear to allow AMID entry.

Figure 10 Policy Server AMIDs Dialogue



- Select a policy server and click on the "+" button and a window will appear to allow you to input AMID values. The MCS will ensure that the AMIDs for each Session Manager / policy server combination are unique. The voice/video/image service AMID values may be the same within each Session Manager/PS assignment.

Figure 11 Add Policy Server AMID



a. **Voice AMID:** value which represents the voice service type. Value between 0-4,294,967,295.

b. **Video AMID** - value which represents the video service type- value between 0-4,294,967,295.

c. **Image AMID** - value which represents the image (fax) service type- value between 0-4,294,967,295.

- Select 'Apply' and the Policy Server AMIDs are will be configured.
- Repeat these steps for each active session manager.

126.2.9 Setting up Diffserv for PCMM

The DiffServ parameters used for PCMM come from the existing QoS provisioning in the service package. The PCMM and QoS Services must be assigned to a domain, and both services created as part of a service package. The service is then assigned to all users you wish to have the PCMM service enabled. These associations are done using the Provisioning Client interface.

126.2.9.1 Assigning DSCP values to a Service Package

To assign the QoS service to the domain, from the Provisioning Client, select Services -> Assign Services.

Figure 12 Assigning Services

In the Assign Services window select the domain to add the QoS service package to and then click the Continue button.

Figure 13 Assigning Services to a Domain

To enable the QoS Service on the domain, from the Assign services to domain... window select QoS (a checked box to the left of the service name) from the list of available services, and once selected, click the Save button at the bottom of the screen.

To add QoS to an existing service package, under your Domain, open Service Package then List Packages.

Figure 14 Listing Service Packages

On the Service package list for domain … window to the right, select Details-Modify next to the Package you wish to add the service to.

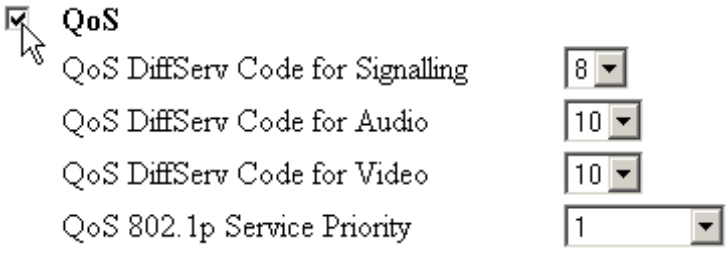
Figure 15 Package Name Details

In the window Package details for package everything belonging to domain...., select the check box to the left of the QoS Service, and Verify that the DiffServ values are correct for your domain. You can use the pull down menus to select the values for the users who subscribe to the service package.

The values in the fields represent the decimal representation of the high-order 6 bits of the DSCP/TOS field to be set in the IP header. To select the value for “expedited forwarding”, for example, choose a value of 46 (decimal). This corresponds to an IP header bit pattern of 1011 1000, where the low-order 2 bits are always set to zeros.

Note that PCMM signaling does not use the QoS DiffServ Code for Signalling.

Figure 16 Setting QoS DiffServ for a Package



If the pulldown boxes don’t have the DSCP value you want, you can define new DSCP values as follows:

Otherwise, click “Save and Enforce Now” to have the values updated, or “Save and Enforce Later” for that outcome.

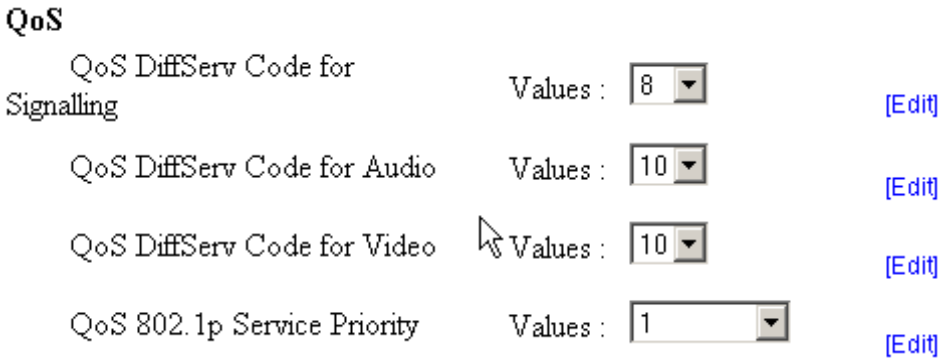
126.2.9.2 Defining New DSCP Values

To create new DSCP values for PCMM, from the Provisioning Client, open Services -> Define Service Parameters, then scroll down to the QoS Section.

Figure 17 Defining Service Parameters

In the List of available services window, scroll down to the QoS Section. If you wish to use a value that is not in the pre-defined list, then select the [edit] hyperlink to the right of the QoS fields,

Figure 18 QoS DiffServ Settings

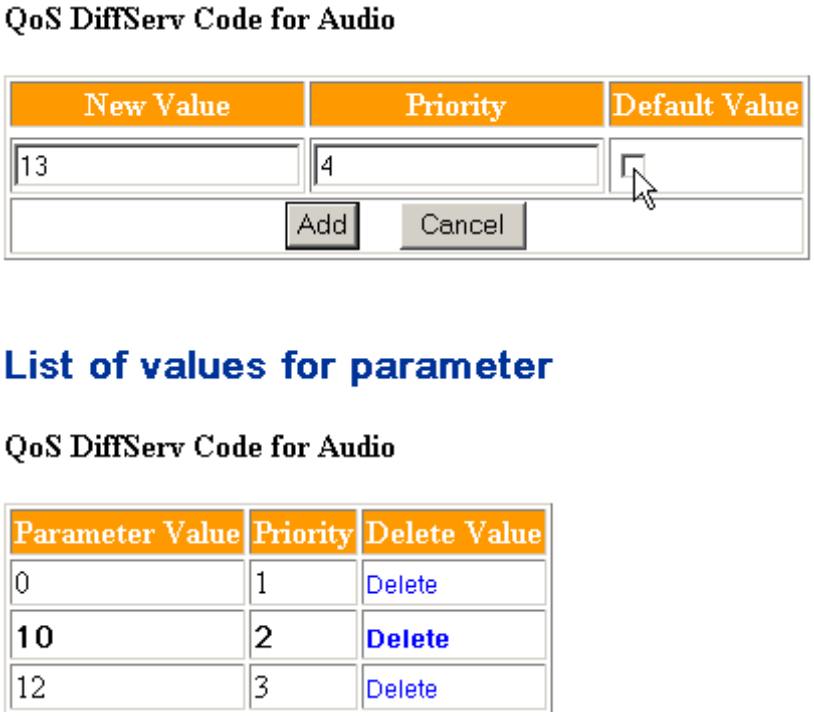


In the picture below the provisioner has chosen to edit the values for the Audio DiffServ value. After selecting edit, the window Add new parameter values for parameter will appear and allow you to add new values, assign priorities to the values, and select if it is the default value.

If you wish to make your new DSCP value the default for all new service packages, check the Default Value checkbox prior to clicking “Add” to add the new value. The default value will be displayed in the values list in bold font.

In the example below, we have chosen to add the value 13 with priority 4, and are about to select this as the default value for audio. If priority 4 already exists, the existing priority 4 value must be deleted before the new value can be added, by selecting the Delete, under the Delete value column.

Figure 19 QoS DiffServ Code for Audio



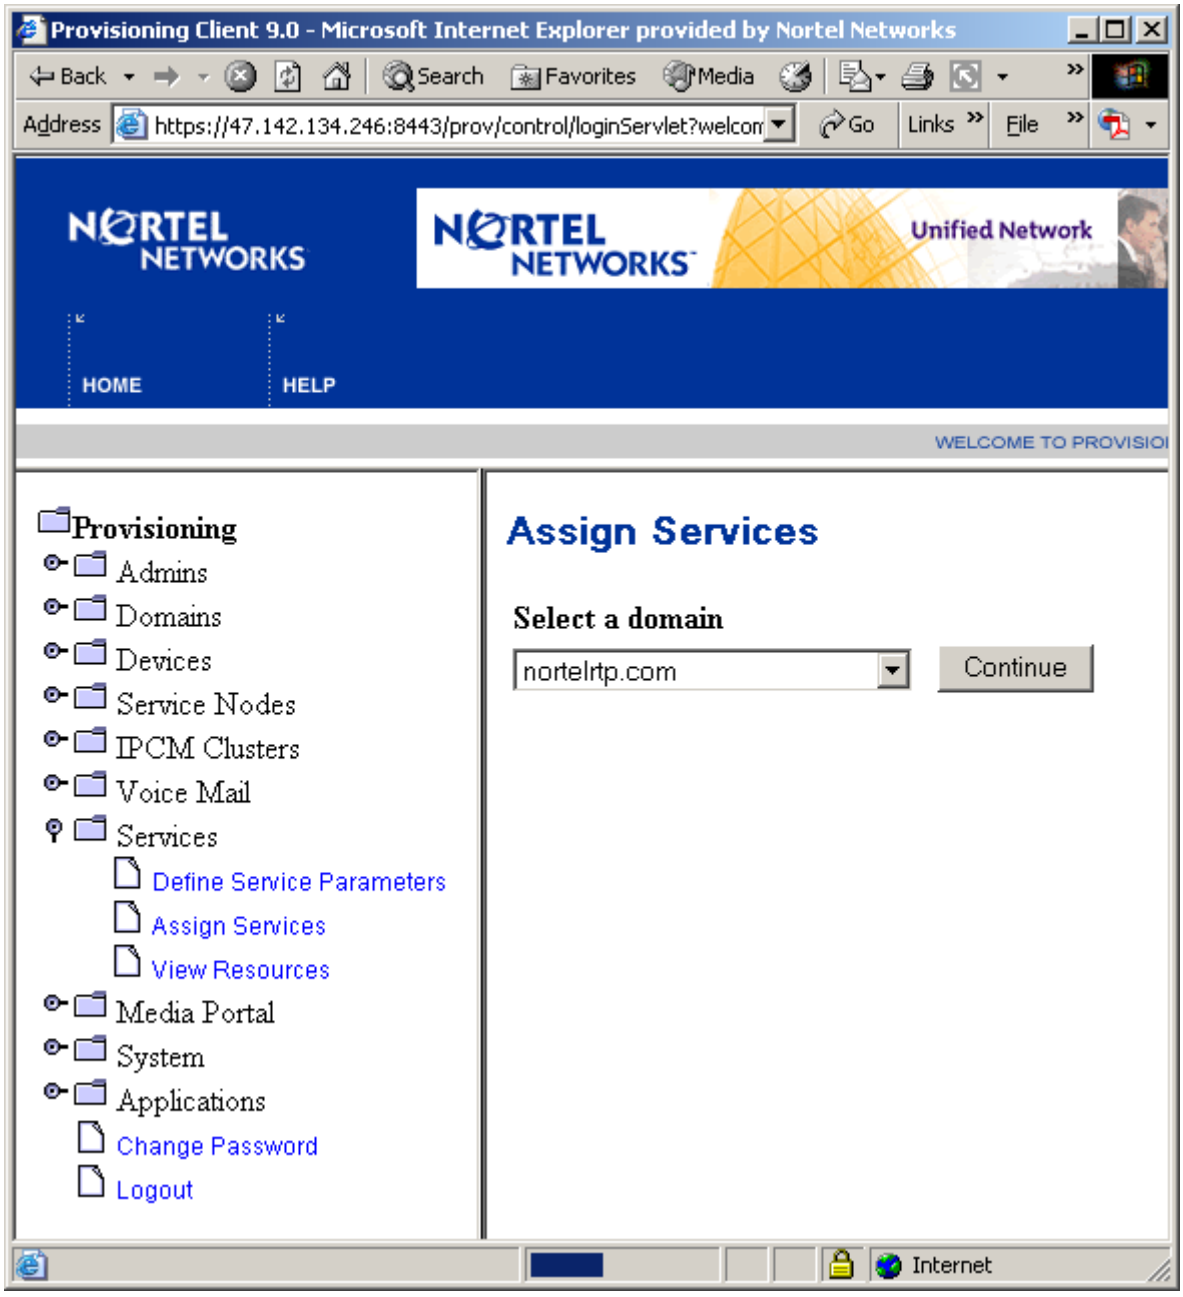
126.2.10 Assigning PCMM Capability to a Subscriber

The ability to provide managed quality of service on a per call / per subscriber level for cable SIP calls is implemented through the use of a new service called PacketCable Multimedia or PCMM. This new service is service package/ domain/sub-domain enabled/disabled through the Provisioning Manager on the MCS.

The steps required to assign the PacketCable Multimedia capability on the Provisioning Manager to a subscriber are:

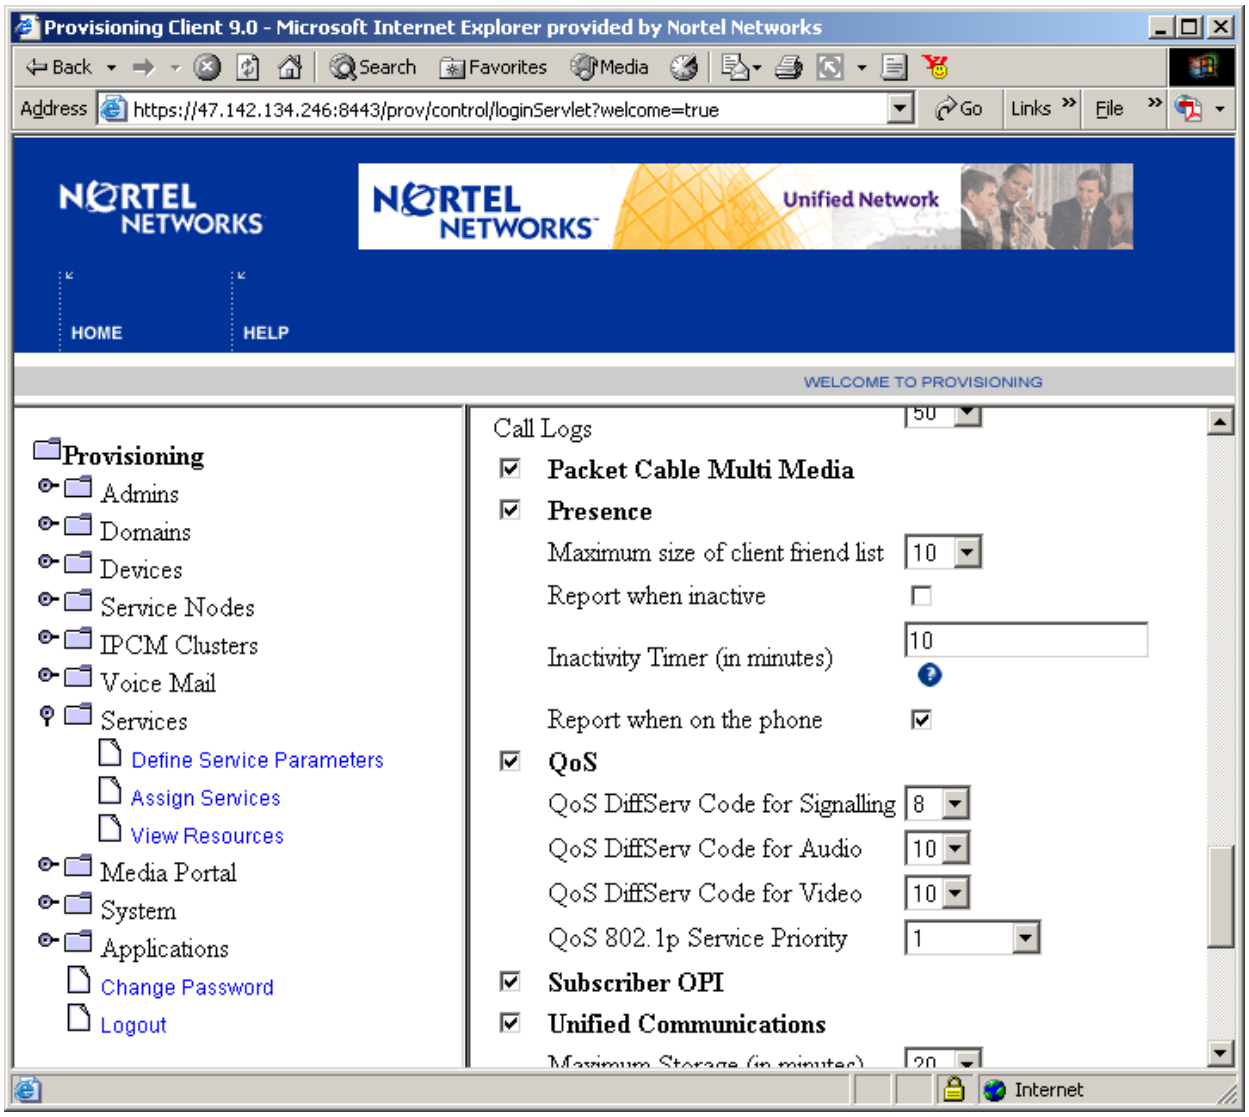
- Create a new domain or sub-domain as desired for PCMM subscribers.
- Open the MCS Provisioning Client, expand the “Services” item and click on “Assign Services”

Figure 20 Provisioning Client for Services



- Select the domain or sub-domain that you want to assign PCMM capability to from the pull-down box and click “Continue” and you will see the list of services will show up in the right-hand frame. Scroll down until you see the “PacketCable Multimedia” checkbox. Check the box and then click “Save” at the bottom of the frame.

Figure 21 Provisioning PacketCable Multimedia

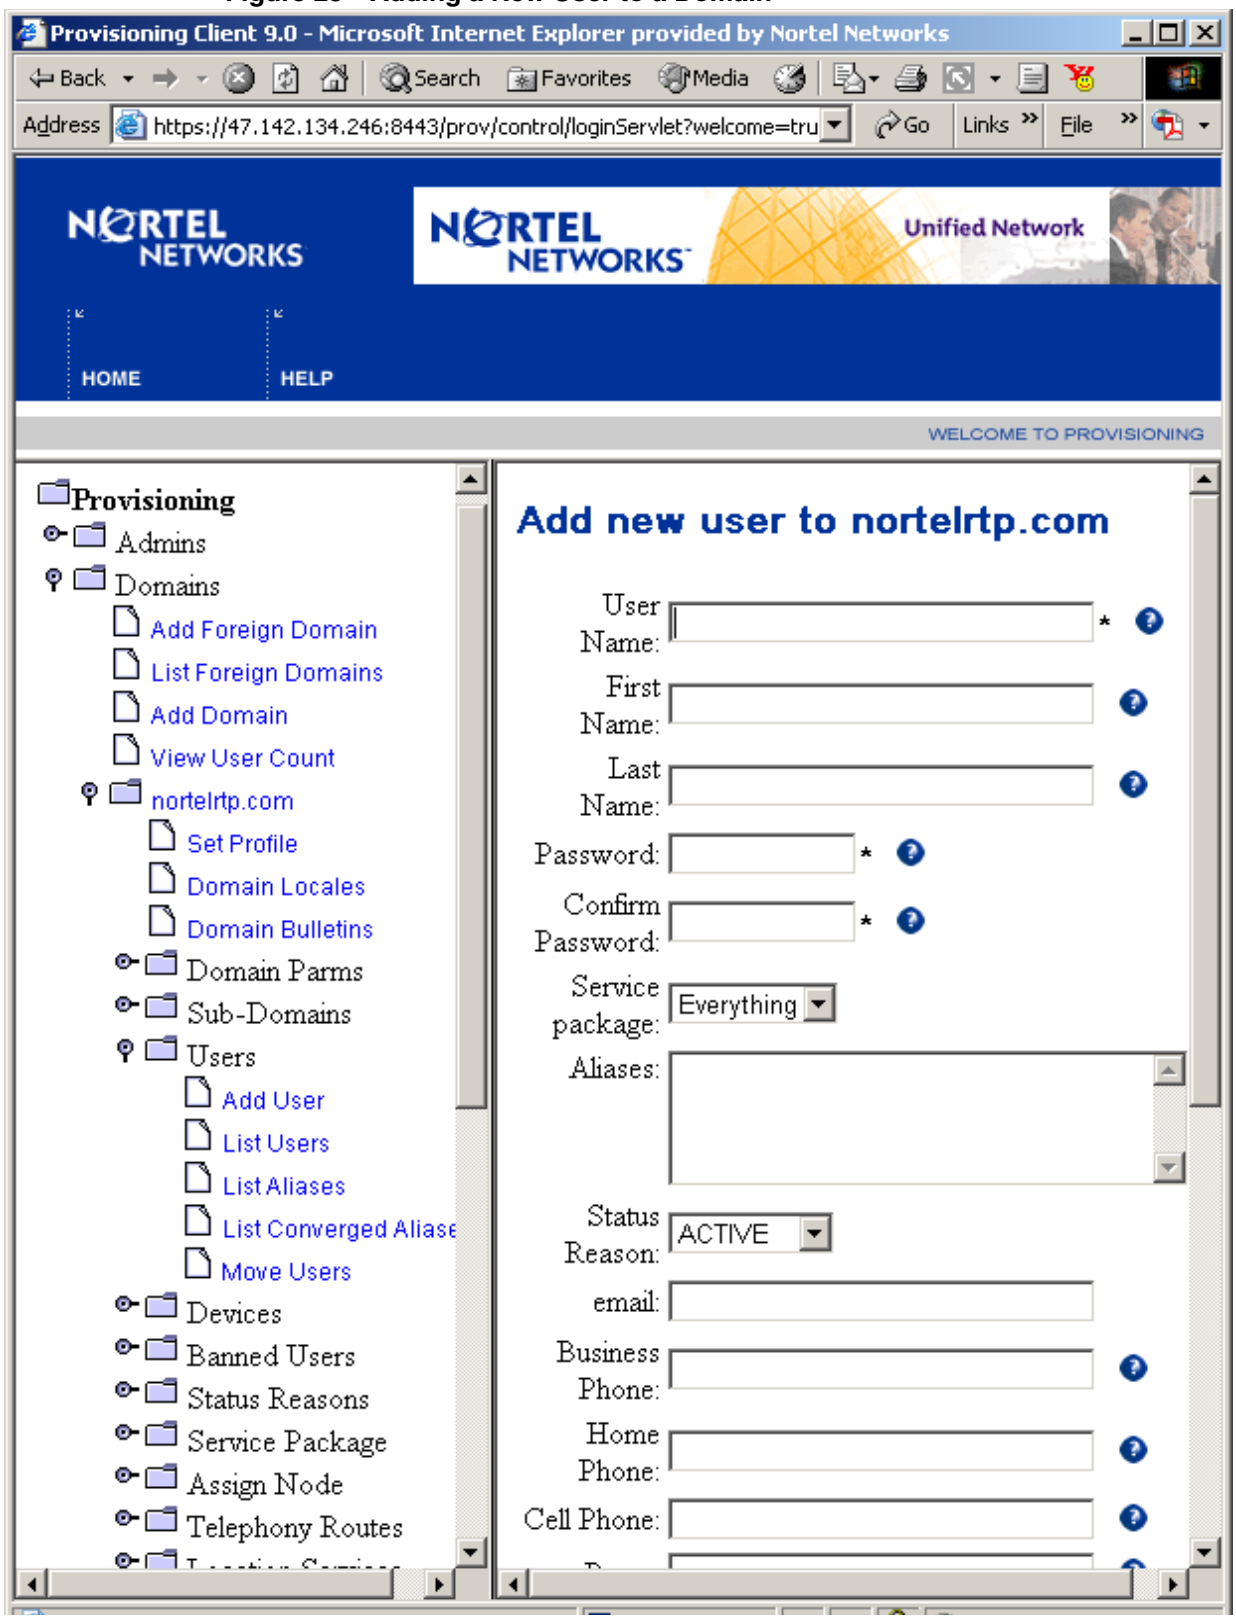


- Expand the desired domain/subdomain icon and create a service package with the PCMM service selected by clicking on “Create Package”.

Figure 22 Creating a new Package for a Domain

- Again under the specific domain/sub-domain, under the ‘Users’ icon select ‘Add User’ icon and fill in the required fields using the service package name created above.

Figure 23 Adding a New User to a Domain



The service is now assigned to a subscriber.

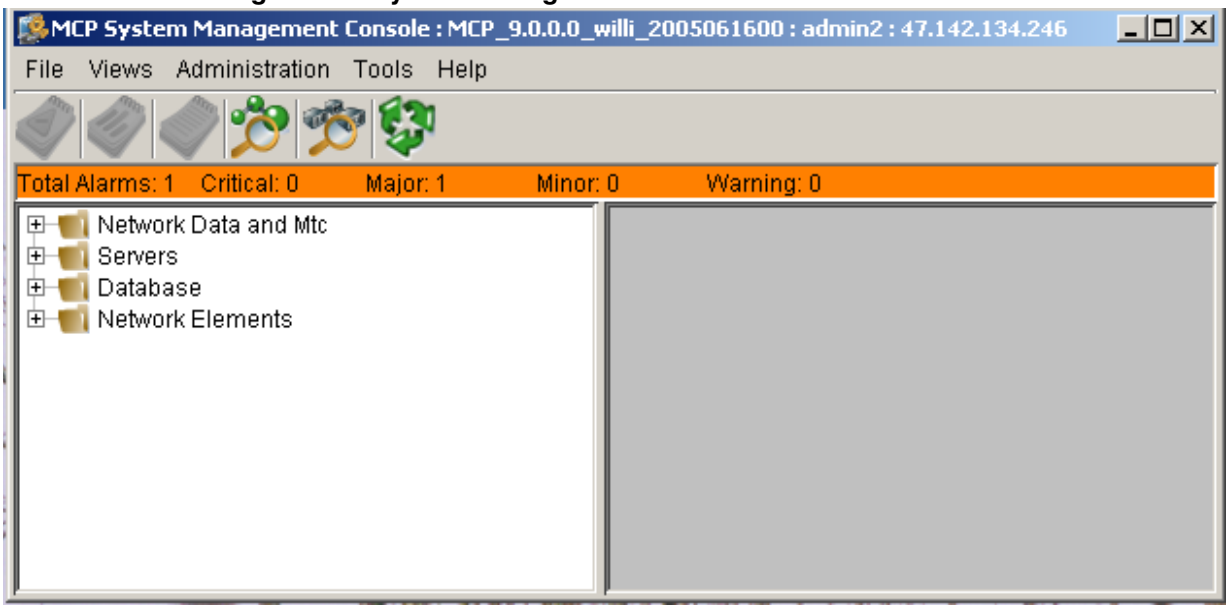
126.2.11 Checking for PCMM Alarms and Logs

As soon as the policy server is configured, the CS2000 will start trying to communicate with it. If this communication fails, a session manager alarm will be raised indicating that the PCMM signaling link cannot be setup. When the PCMM signaling link is down, calls will proceed, but without managed quality of service in the HF/C network.

To check for PCMM alarms, do the following:

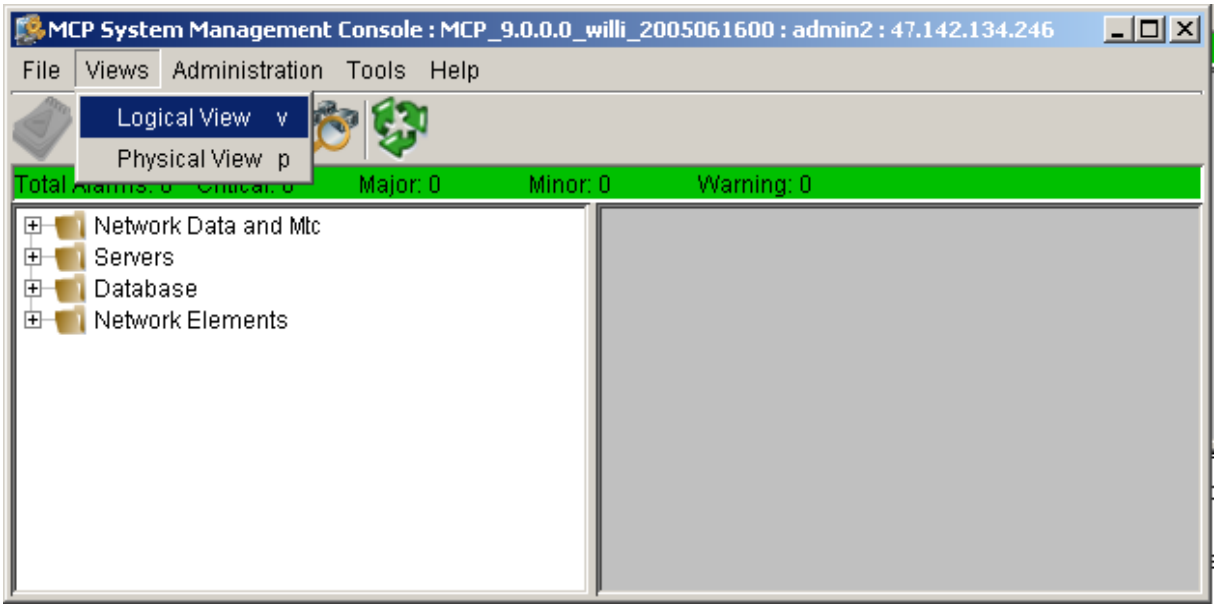
- Login to the System Management Console
- Once you successfully login you will see a screen like the following:

Figure 24 System Management Console



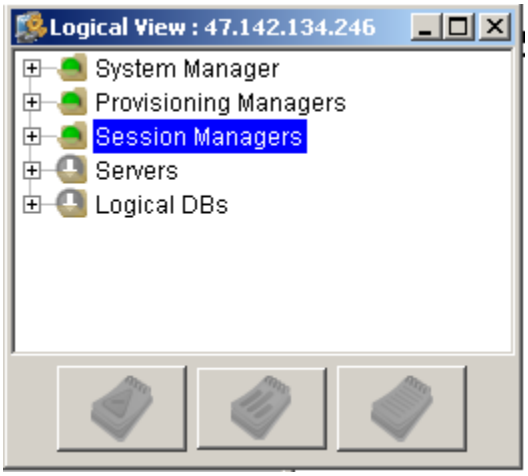
- Note the banner just beneath the tool-bar with a summary of the alarms for the SS-L. If there are any alarms, continue with the next steps to view the alarm details. If no alarms are present, then the PCMM signaling link is operational.
- Start a Logical View of your SS-L as follows:

Figure 25 Starting a Logical View of the MCP System



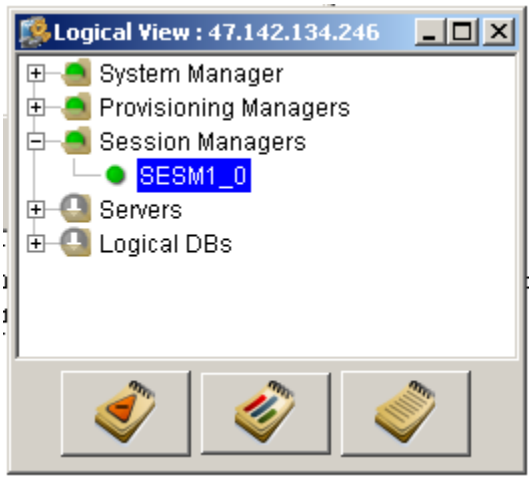
- This will cause a window like the following to appear:

Figure 26 MCP System Logical View



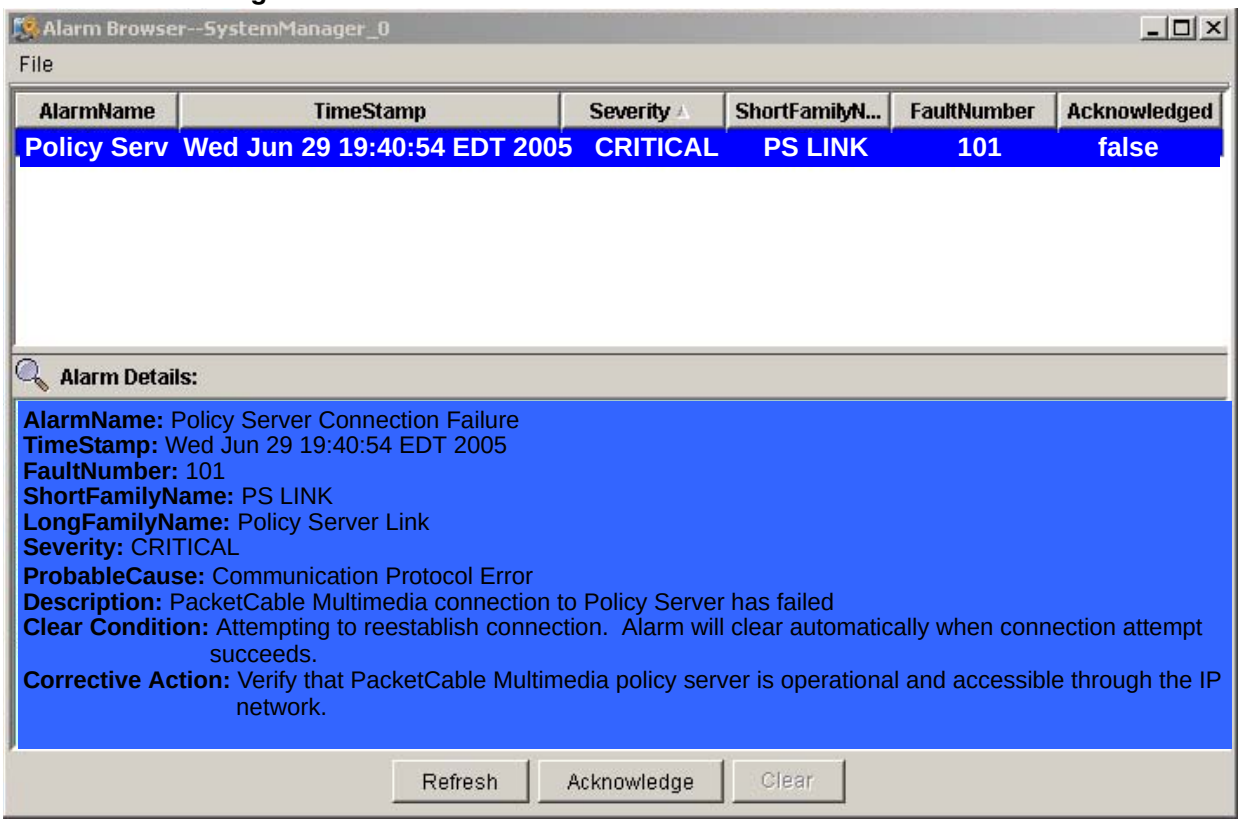
- Expand Session Managers by clicking the "+" to the left of it and highlight a session manager as follows:

Figure 27 Selecting a Session Manager



- Click the button on the lower left to view the alarm browser as follows:

Figure 28 Alarm Browser for PS Connection Failure



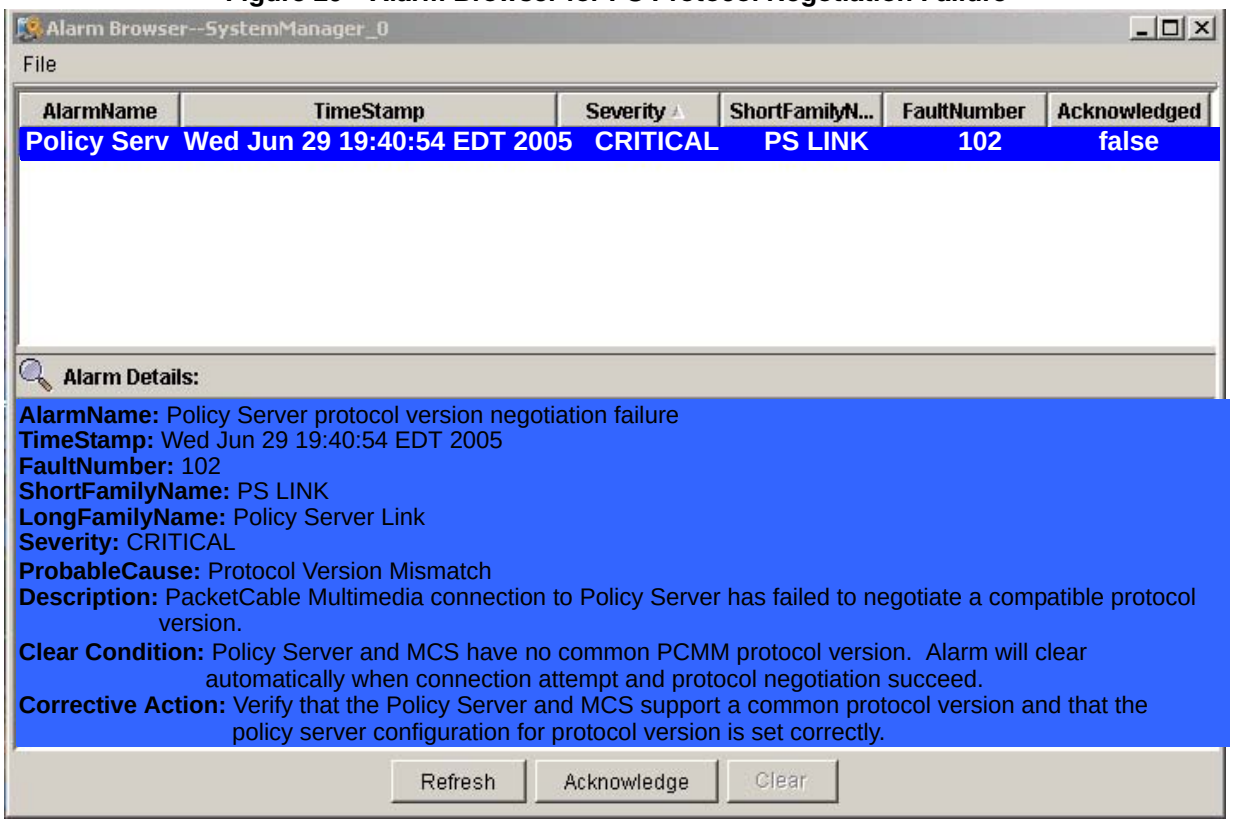
- The alarm view can be manually refreshed by clicking the “Refresh” button.
- Look for alarms with AlarmName “Policy Server Connection Failure” in the upper half of the window. These are PCMM signaling link alarms.

- If you see one, highlight it and the alarm details will be displayed in the lower half of the window.

If you have a PCMM signaling link alarm, all SIP calls from the session manager with the failed PCMM connection will receive best-effort QoS until the problem is resolved. Please refer to the Troubleshooting section of this document for next steps.

Here is an example of the PCMM protocol negotiation alarm that is raised when the PCMM connection fails to come up due to protocol negotiation failure.

Figure 29 Alarm Browser for PS Protocol Negotiation Failure



Following is a summary of all the PCMM alarms and the conditions upon which they are asserted and cleared.

Table 7: PCMM Alarm Conditions

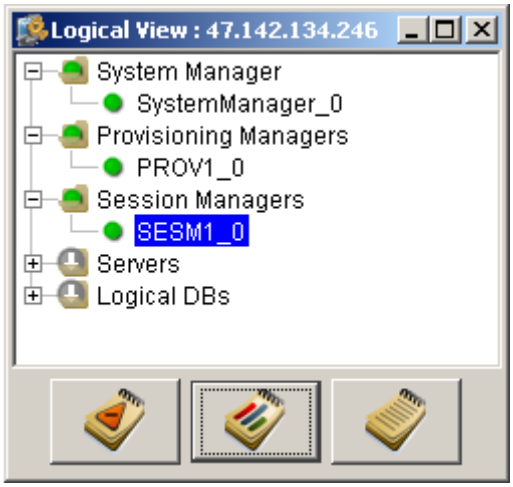
Alarm Name	Severity	Assert	Clear
Policy Server Connection Failure	Critical	Connection drop TCP-layer connection failure Initialization sequence failure other than protocol negotiation	Successful completion of initialization sequence. Deletion of PS from configuration database System or unit shutdown PCMM disabled
Policy Server Protocol Version Negotiation Failure	Critical	Protocol version negotiation failure	Successful completion of protocol negotiation.
PCMM Partial Configuration	Minor	First call to use a policy server for which the session manager AMIDs have not been configured.	Session manager AMIDs successfully configured.

126.2.12 Viewing Operational Measurements

There are a number of operational measurements associated with PCMM. To view PCMM OMs follow this procedure:

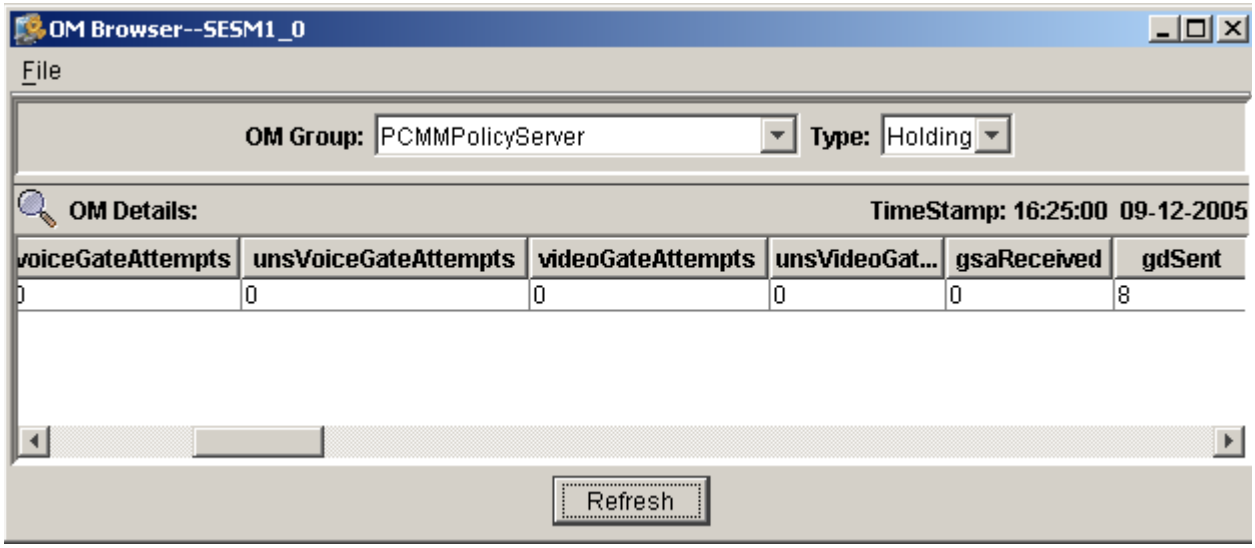
- Pull up the logical view of the MCS as follows:
- Highlight the session manager that you are interested in:

Figure 30 MCP System Logical View



- Click the center button at the bottom of the Logical View window to bring up the OM browser. You will see a window like the following:

Figure 31 Session Manager OM Browser Example



- From the OM Group pull-down menu, select “PCMMAggregate” to access the session manager-wide PCMM OMs. PCMM Aggregate OMs indicate usage of resources that are not specific to any particular policy server.
- Select “PCMMPolicyServer” to access the per-policy server PCMM OMs.

The following tables describe the PCMM operational measurements.

Table 8: PCMM Aggregate Operational Measurements

OM Name	Description
incomingMsgQHighWater	When incoming PCMM signaling messages arrive at the session server they are queued for processing. This OM indicates thehighest percentage used for the incoming PCMM message queue. This value represents the high water mark since the system was started. It is not reset each time the OMs are reported. If this queue gets above ~90%, it may indicate a problem with the PCMM. Please contact your next level of support for assistance.
transactionQHighWater	When the session server sends PCMM messages, the outgoing messages are queued for processing. This OM indicates the highest percentage used for the outgoing PCMM message queue. This value represents the high water mark since the system was started. It is not reset each time the OMs are reported. If this queue gets above ~90%, it may indicate a problem with the PCMM. Please contact your next level of support for assistance.
outstandingQHighWater	After the session server sends a PCMM message to the policy server for processing, the message is held in the outstanding transaction queue until a response is received (or until the transaction times out). This OM indicates the highest percentage used for the outstanding PCMM message queue. This value represents the high water mark since the system was started. It is not reset each time the OMs are reported. If this queue fills up, the oldest outstanding transactions will be removed to make room for newer transactions. This queue can fill up if the policy server is not responding or is responding slowly.
voiceGateAttempts	Total number of PCMM voice half calls processed across all policy servers connected to this session server.
unsVoiceGateAttempts	Total number of unsuccessful PCMM voice half calls processed. There are a number of reasons that a half call might fail to get managed QoS. These include: internal resource errors, no response to transaction, COPS connection down, Gate-Set-Err received from the policy server, etc. Calls that fail to get managed QoS receive best-effort QoS.
unsupCodecVoiceGateAttempts	Total number of PCMM voice half calls with an SDP containing at least one codec for which bandwidth could not be calculated. In order to reserve and commit bandwidth for a call, a mapping must be made between the codec and the flow-spec describing the network resources required. If this mapping fails, then the call might not get optimal bandwidth for managed QoS.

Table 8: PCMM Aggregate Operational Measurements

OM Name	Description
videoGateAttempts	Total number of PCMM video half calls processed across all policy servers connected to this session server.
unsVideoGateAttempts	Total number of unsuccessful PCMM video half calls processed. There are a number of reasons that a half call might fail to get managed QoS. These include: internal resource errors, no response to transaction, COPS connection down, Gate-Set-Err received from the policy server, etc. Calls that fail to get managed QoS receive best-effort QoS.
unsupCodecVideoGateAttempts	Total number of PCMM video half calls with an SDP containing at least one codec for which bandwidth could not be calculated. In order to reserve and commit bandwidth for a call, a mapping must be made between the codec and the flow-spec describing the network resources required. If this mapping fails, then the call might not get optimal bandwidth for managed QoS.
outstandingDiscStale	The number of transactions that were discarded because no response was received from the policy server or because the outstanding transaction queue was full and the oldest transaction waiting for a response was removed to make room for a new transaction.
unkMediaGateAttempts	The number of PCMM gate attempts that could not be processed because the media type was unknown (i.e. not voice, video, or image). Calls that fail to get managed QoS receive best-effort QoS.

Table 9: PCMM Policy Server Operational Measurements

OM Name	Description
numInitializations	Number of times the policy server COPS connection successfully completed the PCMM initialization sequence.
cnxPSDrop	Number of times the policy server gracefully closed the COPS TCP connection (i.e. in a way that caused a TCP FIN message to be sent from the policy server to the session server).
cnxDropProtTimeout	Number of times the connection was dropped by the session server due to lack of PCMM response from the policy server. This could be caused by failure of the session server to receive keep-alive messages or connection initialization sequence messages from the policy server (either because the policy server never sent them or the network prevented them from arriving).

Table 9: PCMM Policy Server Operational Measurements

OM Name	Description
tcpSendFail	Number of times that PCMM messages had to be discarded due to the outgoing TCP buffer being full. Normally this happens if the policy server is not keeping up with the rate of messages being sent from the MCS. TCP send failures can also occur if the network quality is poor, causing a lot of retransmissions.
transDiscLinkDown	Number of PCMM transactions that were discarded due to the PCMM signaling link being down. Since we cannot predict how long a PCMM signaling link might be down, transactions are discarded until the connection is restored. Half-calls whose PCMM transactions are discarded will get "best-effort" quality of service.
transDiscStale	Number of PCMM transactions that were discarded because no response was received from the policy server for more than seven seconds. Or, if the outstanding transaction queue is full, the number of oldest transactions that were discarded to make room for new outstanding transactions.
voiceGateAttempts	Total number of PCMM voice half calls processed for this policy server.
unsVoiceGateAttempts	Total number of unsuccessful PCMM voice half calls processed. This number includes unsuccessful voice calls for all possible reasons.
videoGateAttempts	Total number of PCMM video half calls processed for this policy server.
unsVideoGateAttempts	Total number of unsuccessful PCMM video half calls processed. This number includes unsuccessful video calls for all possible reasons.
gsaReceived	Total number of Gate-Set-Ack messages received from the policy server.
gdSent	Total number of Gate-Delete messages sent to the policy server.
upVoiceGSEReceived	Total number of Gate-Set-Err messages received from the policy server for upstream voice gates. This OM is incremented for all Gate-Set-Error messages regardless of the failure reason.
upVoiceGSENoResources	Number of Gate-Set-Err messages for upstream voice gates with error code 1 - Insufficient Resources
upVoiceGSEUnkGateId	Number of Gate-Set-Err messages for upstream voice gates with error code 2 - Unknown GateID

Table 9: PCMM Policy Server Operational Measurements

OM Name	Description
upVoiceGSEOther	Number of Gate-Set-Err messages for upstream voice gates with error code 127 - Other, Unspecified Error
dnVoiceGSEReceived	Total number of Gate-Set-Err messages received from the policy server for downstream voice gates. This OM is incremented for all Gate-Set-Error messages regardless of the failure reason.
dnVoiceGSENoResources	Number of Gate-Set-Err messages for downstream voice gates with error code 1 - Insufficient Resources
dnVoiceGSEUnkGateId	Number of Gate-Set-Err messages for downstream voice gates with error code 2 - Unknown GateID
dnVoiceGSEOther	Number of Gate-Set-Err messages for downstream voice gates with error code 127 - Other, Unspecified Error
gseInvSubscr	Number of Gate-Set-Err messages for voice and video, upstream and downstream gates with error code 13 - Invalid Subscriber ID
gseInvAMID	Number of Gate-Set-Err messages for voice and video, upstream and downstream gates with error code 14 - Unauthorized AMID
upVideoGSEReceived	Total number of Gate-Set-Err messages received from the policy server for upstream video gates. This OM is incremented for all Gate-Set-Error messages regardless of the failure reason.
upVideoGSENoResources	Number of Gate-Set-Err messages for upstream video gates with error code 1 - Insufficient Resources
upVideoGSEUnkGateId	Number of Gate-Set-Err messages for upstream video gates with error code 2 - Unknown GateID
upVideoGSEOther	Number of Gate-Set-Err messages for upstream video gates with error code 127 - Other, Unspecified Error
dnVideoGSEReceived	Total number of Gate-Set-Err messages received from the policy server for downstream video gates. This OM is incremented for all Gate-Set-Error messages regardless of the failure reason.
dnVideoGSENoResources	Number of Gate-Set-Err messages for downstream video gates with error code 1 - Insufficient Resources
dnVideoGSEUnkGateId	Number of Gate-Set-Err messages for downstream video gates with error code 2 - Unknown GateID
dnVideoGSEOther	Number of Gate-Set-Err messages for downstream video gates with error code 127 - Other, Unspecified Error

Table 9: PCMM Policy Server Operational Measurements

OM Name	Description
grsClose	Total number of Gate-Report-State messages received indicating that a gate was closed by the CMTS for all reasons.
grsCloseResReassign	Number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 1 - reservation reassignment.
grsCloseMacLayer	Number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 2 - lack of DOCSIS MAC-Layer responses
grsCloseT1	PCMM timer T1 specifies the number of seconds a PCMM gate can be authorized but not reserved. This OM indicates the number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 3 - timer T1 expiration
grsCloseT2	PCMM timer T2 specifies the number of seconds a PCMM gate must hold bandwidth reserved in excess of what was committed. Number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 4 - timer T2 expiration
grsCloseResMaint	Number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 6 - lack of reservation maintenance
grsCloseT4	Number of Gate-Report-State messages received indicating that a gate was closed by the CMTS due to reason 8 - timer T4 expiration.
grsNotif	Total number of Gate-Report-State messages received indicating a change of gate state (for any reason) that did not result in the gate being closed.
grsNotifT3	Number of Gate-Report-State messages received indicating that a gate was transitioned to the Committed-Recovery state by the CMTS due to the T3 timer expiring. If the T3 timer expires frequently, you may wish to increase the T3 timer value to a longer duration.

126.2.13 Changing Policy Server Attributes

Some policy server attributes can be changed with no service impact. Other attributes require a re initialization of the PCMM signaling link. The policy server name cannot be changed without deleting and re adding the policy server.

126.2.13.1 Changes requiring a PCMM connection reinitialization

Policy server attributes that define the address of the policy server or are communicated to the policy server only when the connection is started require

that the connection be re initialized. Changing these fields will cause the PCMM signaling connection between the MCS and the policy server to be dropped and immediately reestablished. Calls being setup during the short interval when the PCMM signaling link is down will proceed, but with best-effort quality of service. Changing any of the following fields will cause a PCMM connection reinitialization.

- Policy Server Address
- Policy Server Port
- Protocol Version
- Keep-Alive Timer

See section 126.2.7 on page 1182 for a description of policy server attributes.

When the "Apply" button is clicked after changing any of these fields, a warning dialog will be displayed indicating the consequences of changing these fields and asking you to confirm the operation. Clicking "Yes" will save the changes and reinitialize the connection. Clicking "No" will revert to the prior values.

126.2.13.2 Changes that take effect immediately

The remaining policy server fields can be changed without bouncing the policy server connection. They are:

- Timer T1
- Timer T2
- Timer T3
- Timer T4

See section 126.2.7 on page 1182 for a description of the PCMM protocol timers T1 through T4.

These values will be used for the next call that is started after the "Apply" button is clicked to save the changes.

126.2.14 Removing PCMM Capability from a Subscriber

There are two ways to remove PCMM capability from a subscriber:

- Change the service package that the subscriber is assigned to so that it no longer has the PacketCable Multimedia box checked.
- Change the subscriber to use an existing service package that does not have the PacketCable Multimedia capability assigned.

126.2.15 Deleting a Policy Server and its associated AMIDs

A policy server may be deleted using the MCS System Management Console. Before a policy server can be deleted, however, the AMIDs associated with the policy server on all active session managers must be deleted first. A window displaying an error message will appear if an attempt is made to delete a policy server when an AMID is still provisioned against that policy server on any active session manager.

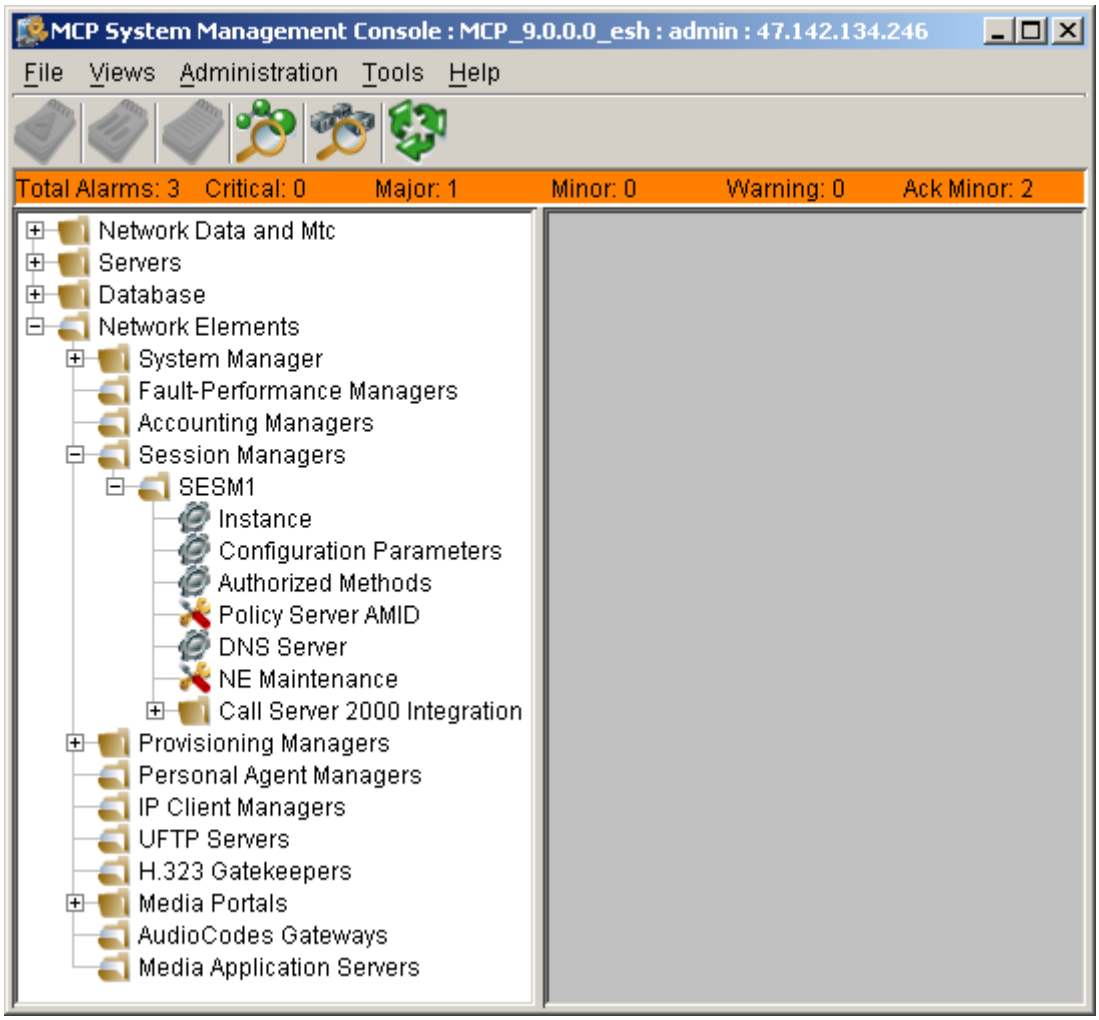
In order to delete the policy server:

- Expand the “Network Elements” and “Session Managers” items

Figure 32 System Management Console for Network Elements

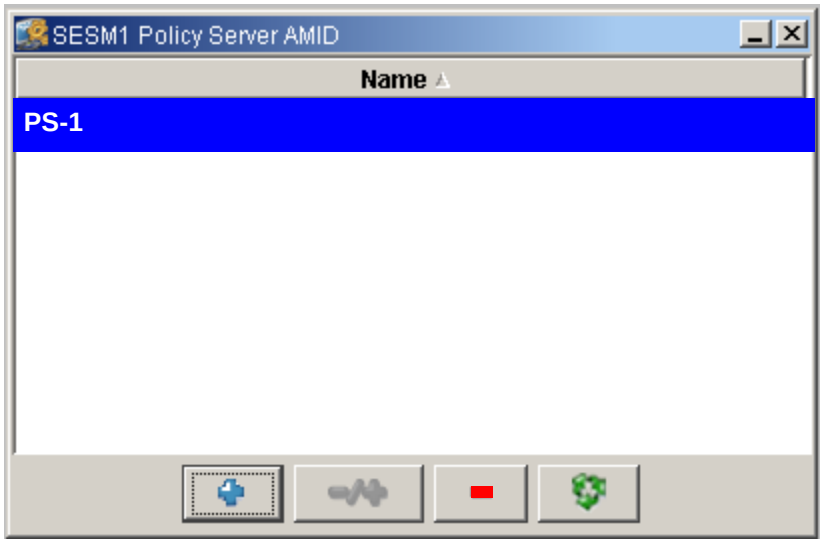
- Select and expand each active session manager

Figure 33 System Management Console for Session Managers



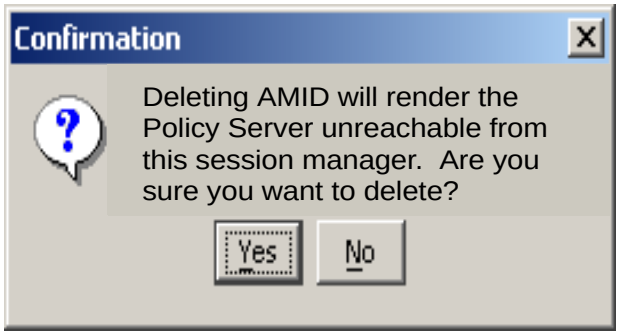
- Click Policy Server AMID and a window will appear showing the assigned policy servers.

Figure 34 Session Manager AMID Dialogue



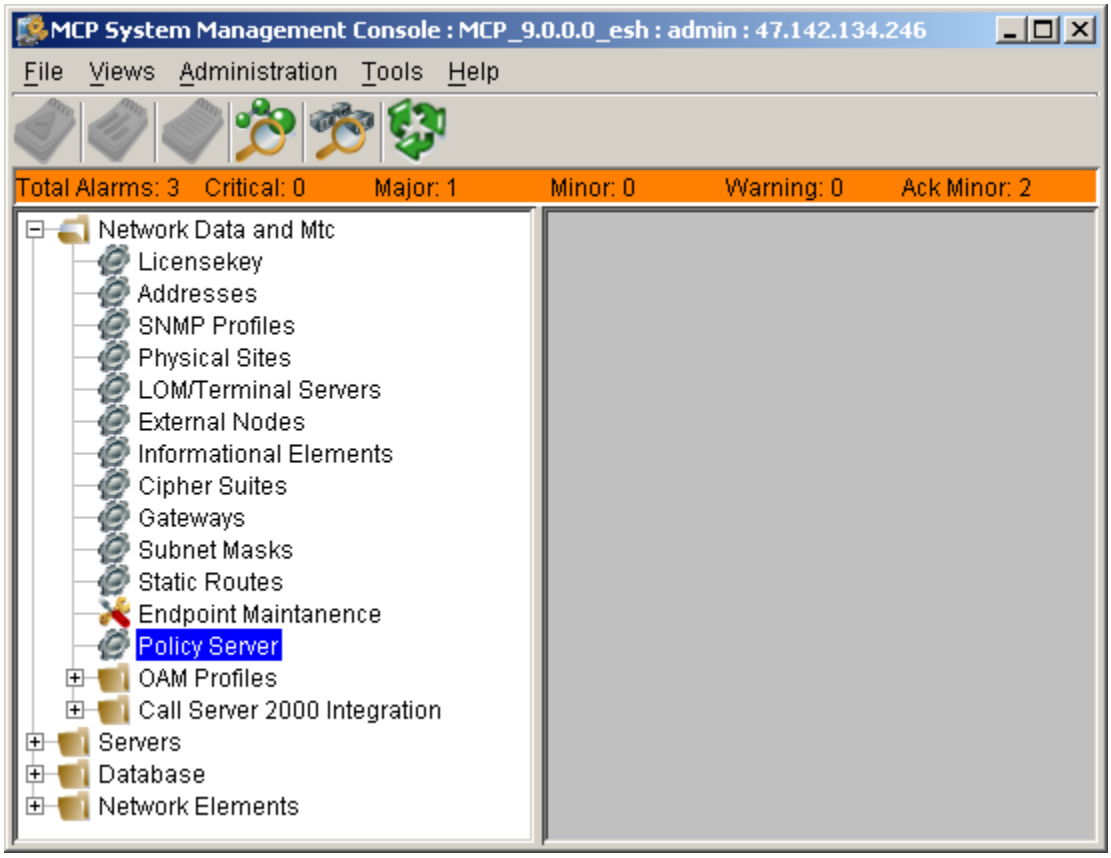
- Highlight the policy server to be deleted <<and the AMIDs will be displayed???>>
- Click the "-" minus button and click "Apply" to remove the AMIDs from that session manager
- A warning dialogue will appear indicating that removal of AMIDs will render the connection from this session manager to the policy server unusable. Once the AMID has been removed and prior to removal of the policy server, a minor alarm will appear for the session managers that no longer have AMIDs (see section 126.2.11 on page 1197). This alarm indicates that a partial configuration is present and will clear once the policy server is deleted.

Figure 35 AMID Delete Confirmation



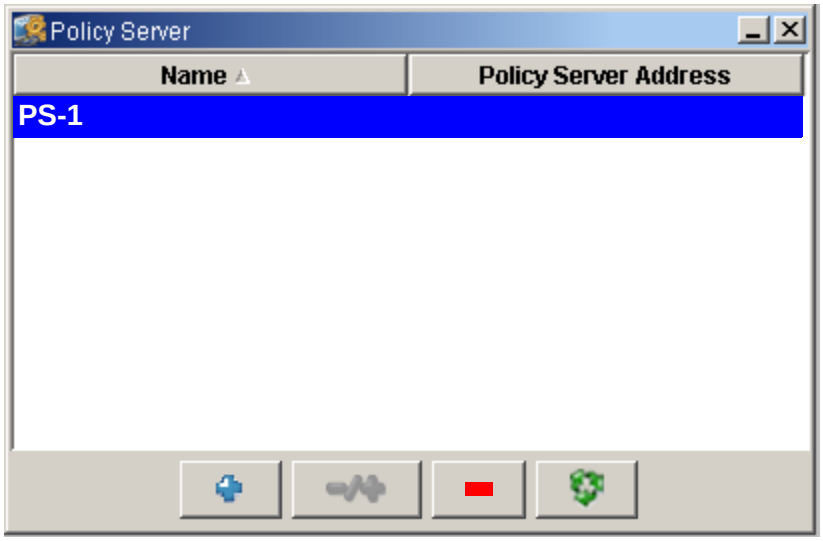
- Repeat above to remove the AMIDs from all active session managers.
- Now that all associated AMIDs have been removed, expand the "Network Data and Mtc" item

Figure 36 System Management for Policy Servers



- Select the Policy Server icon, a window will appear showing the configured policy servers.

Figure 37 Policy Server Dialogue



- Highlight the policy server to be deleted and click the "-" (minus) button and click "Apply" to delete the policy server.

WARNING: Deletion of a Policy Server will cause all new PCMM capable calls to receive best-effort quality of service within the cable network.

126.2.16 Understanding Session Manager Failover

The session manager can be configured for redundancy, thus enabling failover if something goes wrong. This section describes what happens to calls in the event of a failover. A warm failover is when the active unit fails and the standby unit is up and ready to become the active unit. A cold failover happens when there is no standby unit or when the standby unit is not ready to become active.

126.2.16.1 Warm

A stable subscriber session and its managed QoS will survive a warm failover. Subscribers on calls in the conversation phase at the time of the warm failover will not notice that a failover has occurred.

Calls that are held or for any reason have no media packets flowing at the time of the session manager failover may lose their managed QoS if the T3 and T4 timers subsequently expire. The held calls will not be torn down, but they may lose their managed QoS and continue using best-effort QoS.

Calls in the setup phase at the time of the warm failover are not guaranteed to succeed. If they do succeed, they may get only best-effort QoS.

126.2.16.2 Cold

All calls are torn down on cold failover.

126.2.17 Troubleshooting

The following table lists the more common failure modes and gives advice on resolving the problem. In general, always check for alarms first. If an alarm is present, look for logs generated around the same time the alarm was

generated. Also look at PCMM OMs to determine if there are any unexpected peg-counts.

Table 10: PCMM Troubleshooting

Condition	Possible Causes and Corrective Actions
Policy Server connection failure alarm	Incorrect policy server IP address or port. Verify that the policy server IP address and port configuration are correct. Network problem between session manager and policy server. Verify that you can ping the policy server from the session manager. Make sure any firewalls are configured to allow TCP packets between the session manager and policy server. Policy server not running or not configured correctly. Verify that your policy server is operating correctly.
Policy Server protocol version negotiation failure alarm	Protocol version misconfigured. Verify that your PCMM protocol version number is set to the highest protocol that you want to allow for the PCMM connection. For this initial release, the protocol version should be set to 1.0. Policy server is running incompatible software. Verify that the policy server supports the protocol version for which you have configured the CS2000 PCMM protocol version.
Poor voice or video quality	PCMM signaling connection is down. Verify that you don't have any Policy Server alarms. The audio or video codec being use for the call is not supported for PCMM. Calls not using G.711 or G.729 for voice, or H.263 or DIVX for video do not receive managed QoS. Other PCMM signaling problems are occurring. Check your PCMM operational measurements (OMs) to see if any unexpected peg counts are present. Please refer to the OM section of this document for a complete description of all PCMM OMs. Calls active at the time of a failover can lose their managed QoS if they are subsequently placed on hold (no media packets flowing) for longer than the combined length of the T3 and T4 timers. (The T3 and T4 timers are configured against the policy server in the MCP System Management Console.)

126.3 MCP Provisioning Client PCMM Help Information

In lieu of additional PCMM help information in the MCP Provisioing Client the following provides a description PCMM service.

Service Name : PCMM

Parameters : None

Desciption: When assigned to a user thru a service package, this parameter in conjunction with a configured Policy Server will provide the user the ability to receive managed quality of service for all voice and or video sessions. The service is provisioned on a service package level for domains or sub-domains-- see the MCS Provisioning Client Help information under “Defining and Assigning Services” and “Assigning Services and Creating Service Packages”.

126.4 Hardware Requirements or Dependencies

In order to implement the PCMM feature, the MSO needs to have cable network elements that are not supplied by Nortel. These cable network elements include cable modems, CMTSs, and a policy server.

There are no additional CS2000 hardware elements required for PCMM other than what was necessary for a basic SIP lines deployment.

Nortel has tested PCMM with all endpoints supported by the CS2000 SIP lines program, including the following SIP clients:

- Nortel Networks PC Client
- Cisco 7960 SIP phone

126.5 Software Requirements or Dependencies

The policy server and CMTSs in the cable network must support PacketCable Multimedia specification PKT-SP-MM-I02-040930. The cable modems must support DOCSIS 1.1.

The CS2000 components must be at SN09 including the MCS software for PCMM.

126.6 Limitations and restrictions

This initial release of the PCMM service has the following limitations:

- Single policy server per CS2000
- Emergency calls are not distinguished from normal calls with respect to PCMM
- No support for IPSec on the PCMM signaling connection

- No PCMM marking in billing records
- Support for audio codecs G.711 and G.729 only
- Support for video codecs H.263 and DIVX only
- Inability to disable DSCP overwrite
- DSCP must be the same for upstream and downstream flows
- PCMM signaling only for committed state

The following items indicate *optional* protocol elements that are not included in this release of the PCMM service:

- No support for optional Time Based Usage Limits
- No support for optional Volume Based Usage Limits
- PCMM signaling only for committed state
- Only Flow-Spec Traffic-Profile supported
- No support for optional Opaque-Data
- No support for optional state synchronization with policy server
- Single classifier based on media source and destination IP addresses and ports (no classification based on DSCP)

126.7 Interactions

The PCMM feature sets up managed quality of service for SIP line calls originating from or terminating to the cable network. PCMM operates on a half-call basis. This means that PCMM signaling and managed QoS happen only for the half of the call that is in the cable network. For example, an on-net to off-net call will only do PCMM signaling for the originating line half of the call. The trunk half of the call is not touched by PCMM.

The PCMM service works for all call types supported by the CS2000 SIP lines program.

126.7.1 Basic Call

The PCMM feature attempts to set up managed quality of service when the SDP information is known for both of the media endpoints (originating and terminating). If PCMM fails to set up managed QoS, the call proceeds with "best-effort" QoS. Calls will never fail due to PCMM, but it is possible under some error conditions that a call might not receive managed QoS.

126.7.2 Codec Support

The following codecs and packetization rates are supported:

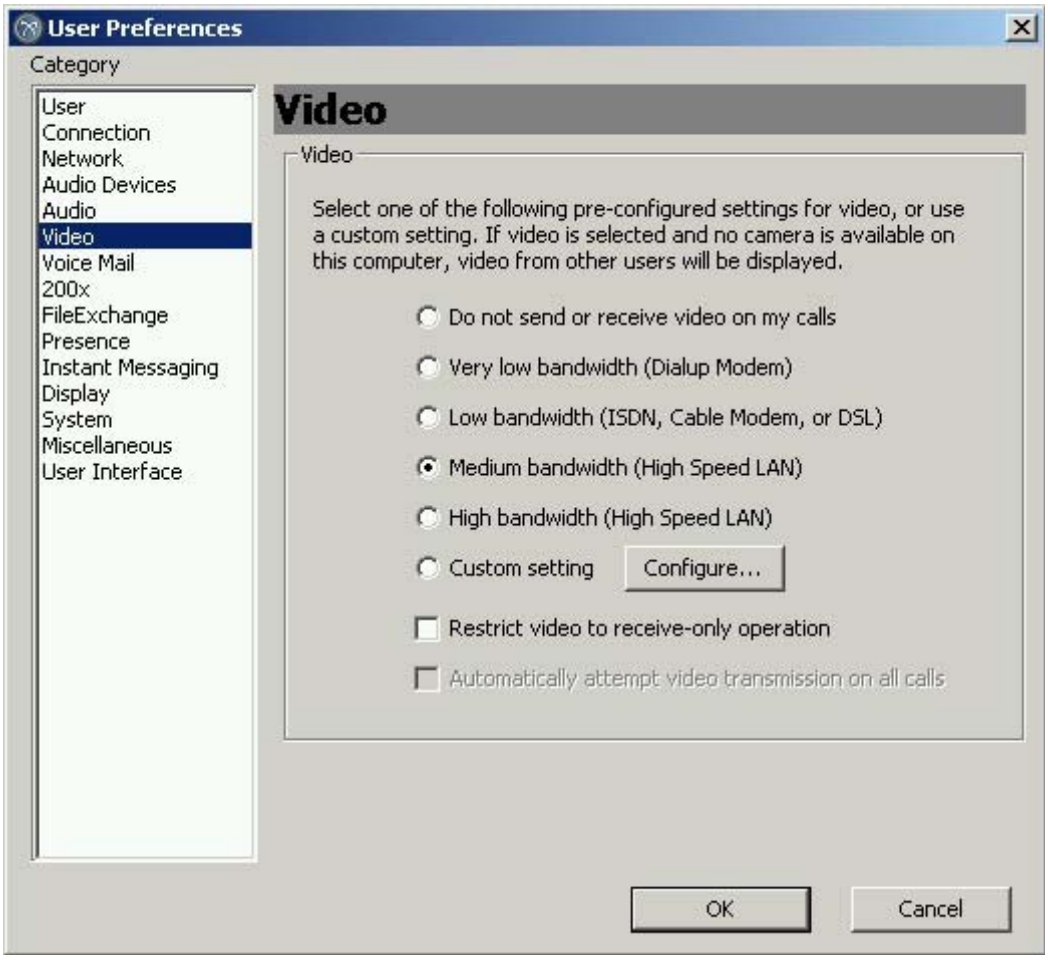
Table 11: PCMM Supported Codec/ptime Combinations

Codec	ptime
PCMU	10 20 30
PCMA	10 20 30
G.729A	10 20 30
H.263	
DIVX	

126.7.3 Supported Video Configuration using Multimedia PC Client

The Nortel Networks Multimedia PC Client provides extensive flexibility in the configuration of video parameters. Not all configurations cans be supported with the PacketCable Multimedia capability.

Figure 38 Multimedia PC Client Video Preferences



There are 4 preset configurations optimized for different bandwidth usage from “very low bandwidth” to “high bandwidth”. Each of these settings can be used with the PacketCable Multimedia capability.

The “custom setting” is not supported for use with the PacketCable Multimedia capability.

126.8 PacketCable Requirements Compliance

The following table lists the PacketCable requirements from PKT-SP-MM-I02-040930 that apply to an application manager and indicates Nortel CS2000 compliance.

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15004	The AMID MUST be a globally unique value assigned to the Application Manager by the service provider.	Yes	MUST	
MMREQ15005	The Application Manager MUST use the assigned AMID in all its interactions with Policy Servers.	Yes	MUST	
MMREQ15011	The Policy Server or Application Manager MUST define the Traffic Profile for a Gate using one of the following: (1) the FlowSpec, (2) DOCSIS Service Class Names, or (3) DOCSIS-Specific Parameters.	Yes	MUST	
MMREQ15014	There MUST be at least one set of Traffic Profile parameters specified when the Gate is first being installed.	Yes	MUST	
MMREQ15017	A controlled load service MUST contain only the TSpec token bucket parameters, and not the RSpec.	Yes	MUST	
MMREQ15018	A guaranteed service MUST contain both the TSpec and the RSpec.	Yes	MUST	
MMREQ15022	If the Application Manager wishes to use this third way of defining a Traffic Profile, it MUST include an object containing the DOCSIS Specific Parameters.	Yes	MUST	
MMREQ15041	To reserve resources, the Policy Server MUST issue a subsequent Gate-Set message with a Traffic Profile that includes the Reserved Envelope.	Yes	MUST	
MMREQ15051	The Reserved envelope MUST always be less than or equal to the Authorized envelope.	Yes	MUST	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15053	However, all requests to modify Authorized, Reserved or Committed envelopes MUST conform to the general rule:	Yes	MUST	
MMREQ15061	In the Committed state, the Application Manager MAY delete the Gate by issuing a Gate-Delete message to the Policy Server, which in turn MUST relay the message onto the CMTS.	Yes	MUST	
MMREQ15073	The Application Manager MUST either refresh the policy by issuing a Gate-Set message, or remove the Gate by issuing a Gate-Delete message.	Yes	MUST	
MMREQ15093	In contrast, PacketCable Multimedia implementations MUST use the TransactionID object to match responses with requests and SHOULD send RPT messages as soon as they are ready.	Yes	MUST	
MMREQ15095	Protocol messages for Gate Control MUST be transported within the COPS protocol messages.	Yes	MUST	
MMREQ15096	The PDP and PEP MUST establish and use a TCP connection for communication, and utilize the mechanisms specified in [17] to secure the communication path.	Yes	MUST	
MMREQ15097	The Application Manager, Policy Server and CMTS MUST use the COPS Common Message format as defined below as the message format for all message exchanges.	Yes	MUST	
MMREQ15098	This field MUST be set to 1.	Yes	MUST	
MMREQ15099	, a solicited decision sent in response to a request) this flag MUST be set to 1.	Yes	MUST	
MMREQ15100	, an unsolicited decision) the flag MUST NOT be set (value = 0).	Yes	MUST	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15101	In keeping with the DQoS model, the first Decision message sent in response to a Request message is a solicited response and its solicited message flag MUST be set.	Yes	MUST	
MMREQ15102	All other Decision messages are unsolicited and the solicited message flag MUST be cleared.	Yes	MUST	
MMREQ15103	All other flags MUST be set to zero.	Yes	MUST	
MMREQ15104	For PacketCable Multimedia use, the Client-Type MUST be set to PacketCable Multimedia client (0x800A).	Yes	MUST	
MMREQ15105	For Keep-Alive messages (Op-code = 9) the Client-Type MUST be set to zero, as the KA is used for connection verification rather than per-client session verification.	Yes	MUST	
MMREQ15106	Messages MUST be aligned on 4-byte boundaries, so the length MUST be a multiple of four.	Yes	MUST	
MMREQ15107	All the objects MUST conform to the same object format where each object consists of one or more 4-byte words with a four-octet header, using the following format.	Yes	MUST	
MMREQ15108	Length is a 2-byte unsigned integer value that MUST give the number of bytes (including the header) that compose the object.	Yes	MUST	
MMREQ15109	If the original length in octets is not a multiple of four, padding MUST be added to the end of the object so that it is aligned to the next 4-byte boundary.	Yes	MUST	
MMREQ15110	Each of these objects MUST conform to the format and rules relating to the individual object as defined in[10].	Yes	MUST	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15111	These objects MUST be placed inside a Decision object, C-Num = 6, C-Type = 4 (Client Specific Decision Data) when carried from PDP to PEP in a Decision message.	Yes	MUST	
MMREQ15113	S-Num and S-Type MUST be one octet.	Yes	MUST	
MMREQ15114	The COPS Length field MUST be two octets.	Yes	MUST	
MMREQ15115	The TransactionID MUST also contain the command type that identifies the action to be taken or response.	Yes	MUST	
MMREQ15116	The TransactionID Object MUST conform to the following format.	Yes	MUST	
MMREQ15118	Gate Command Type is a 2-byte unsigned integer value which identifies the Gate Control message type and MUST be one of the following:	Yes	MUST	
MMREQ15119	The Application Manager MUST include this object in all messages it issues to the Policy Server.	Yes	MUST	
MMREQ15122	The AMID object MUST conform to the following format.	Yes	MUST	
MMREQ15123	The SubscriberID object MUST conform to the following format.	Yes	MUST	
MMREQ15126	The GateID object MUST conform to the following format.	Yes	MUST	
MMREQ15127	The GateSpec object MUST conform to the following format.	Yes	MUST	
MMREQ15128	Bit 0: direction bit, MUST be either zero for a downstream Gate, or one for an upstream Gate.	Yes	MUST	
MMREQ15129	Bit 1: DSCP/TOS enable bit, MUST be either zero to disable DSCP overwrite, or one to enable.	Yes	MUST

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15155	This name MUST be padded with null bytes to align on a 4-byte boundary.	Yes	MUST	
MMREQ15156	The Best Effort object MUST conform to the following specification:	Yes	MUST	
MMREQ15158	The Non-Real Time Polling object MUST conform to the following specification:	Yes	MUST	
MMREQ15161	The Real-Time Polling object MUST conform to the following specification:	Yes	MUST	
MMREQ15164	The Unsolicited Grant object MUST conform to the following specification:	Yes	MUST	
MMREQ15165	The Unsolicited Grant with Activity Detection object MUST conform to the following specification:	Yes	MUST	
MMREQ15167	The Downstream object MUST conform to the following specification:	Yes	MUST	
MMREQ15170	The Event Generation Info object MUST conform to the following specification:	Yes	MUST	Optional - not used
MMREQ15171	Primary-Record-Keeping-Server-IP-Address is a 4-byte field which MUST contain the IPv4 address of the primary RKS to whom event records are to be sent.	Yes	MUST	Optional - not used
MMREQ15172	Primary-Record-Keeping-Server-Port field is a 2-byte unsigned integer which MUST contain the port number on the primary RKS where event records are to be sent.	Yes	MUST	Optional - not used
MMREQ15173	Secondary-Record-Keeping-Server-IP-Address is a 4-byte field which MUST contain the IPv4 address of the secondary RKS to whom records are to be sent if the primary RKS is unavailable.	Yes	MUST	Optional - not used

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15174	Secondary-Record-Keeping-Server-Port is a 2-byte unsigned integer which MUST contain the port number on the secondary RKS where event records are to be sent.	Yes	MUST	Optional - not used
MMREQ15175	Billing-Correlation-ID is a 24-byte field which MUST contain the identifier assigned by the AM or PS for all records related to this session.	Yes	MUST	Optional - not used
MMREQ15176	It MUST NOT be used in any other messages.	Yes	MUST	Optional - not used
MMREQ15177	The Volume-Based Usage Limit object MUST conform to the following specification:	Yes	MUST	Optional - not used
MMREQ15178	The Time-Based Usage Limit object MUST conform to the following specification:	Yes	MUST	Optional - not used
MMREQ15180	It MUST NOT be used in any other messages issued by the PDP to the PEP.	Yes	MUST	Optional - not used
MMREQ15198	Messages that perform gate control between the Application Manager and Policy Server are defined and MUST be formatted as follows.	Yes	MUST	
MMREQ15199	Note that messages from the Application Manager to Policy Server MUST be formatted as COPS Decision messages, and messages from Policy Server to Application Manager MUST be formatted as COPS Report-State messages.	Yes	MUST	
MMREQ15202	For Gate Control command messages, the Context object (C-Num = 2, C-Type = 1) in the COPS Decision message MUST have the R-Type (Request Type Flag) value set to 0x08 (Configuration Request) and the M-Type set to zero.	Yes	MUST	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15203	The Command-Code field in the mandatory Decision-Flags object (C-Num = 6, C-Type = 1) MUST be set to 1 (Install Configuration).	Yes	MUST	
MMREQ15211	Any Application Manager or Policy Server (PDP) with a need to contact a PEP MUST initiate a TCP connection to the PEP on that port.	Yes	MUST	
MMREQ15214	Upon successful receipt of the Client-Open message, the PDP MUST send a Client-Accept message if the protocol version specified in the Version Info object is supported.	Yes	MUST	
MMREQ15215	This message MUST include the Keep-Alive-Timer object, which tells the PEP the maximum interval between Keep-Alive messages.	Yes	MUST	
MMREQ15216	If the protocol version supplied by the PEP is not supported, the PDP MUST send a Client-Close messages with a COPS Error Object specifying error code 4 (Unable to process).	Yes	MUST	
MMREQ15217	After sending the Client-Close, the PDP MUST retain the TCP connection and security association with the PEP so that the PEP can reattempt the COPS initialization without reestablishing the TCP connection and security association.	Yes	MUST	
MMREQ15219	The PDP MUST then send a Client-Close message to the PEP to acknowledge that protocol negotiation has failed.	Yes	MUST	
MMREQ15221	Devices compliant with this specification MUST use a version of 1.0, i.e.	Yes	MUST	
MMREQ15227	Upon receipt of the COPS KA message, the PDP MUST echo a COPS KA message back to the PDP.	Yes	MUST	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15230	All messages from the PDP to the PEP MUST be sent using Client-Specific objects within the Decision object of a COPS Decision message.	Yes	MUST	
MMREQ15233	The Decision messages and Report-State messages MUST contain the same Client-Handle as provided in the initial Request sent by the CMTS when the COPS connection was initiated.	Yes	MUST	
MMREQ15237	The PDP MUST keep track of when KAs are received.	Yes	MUST	
MMREQ15238	If the PDP has not received a KA from the PDP in the time interval specified in [10] or the PDP has not received an error indication from the TCP connection, then the PDP MUST tear down the TCP connection and attempt to re-establish the TCP connection.	Yes	MUST	
MMREQ15239	, Gate-Set, Gate-Info, and Gate-Delete) MUST include (in addition to other mandatory objects) both AMID and SubscriberID objects.	Yes	MUST	
MMREQ15249	At any one point in time, the Committed envelope MUST fit within the Reserved Envelope which MUST fit within the Authorized envelope.	Yes	MUST	
MMREQ15254	For traffic profiles in the form of a Service Class Name, the Service Class Name string MUST exactly match the preexisting Service Class Name on the CMTS.	Yes	MUST	
MMREQ15255	The Gate-Set message MUST contain exactly one GateSpec object, describing one upstream or downstream Gate.	Yes	MUST	
MMREQ15284	: The Application Manager MUST handle received reports.	Yes	MUST

MMREQ15507	A default Assumed Minimum Reserved Traffic Rate Packet Size of 0 SHOULD be used if a specific Assumed Minimum Reserved Traffic Rate Packet size is not required.	Yes	SHOULD	
MMREQ15508	A default Maximum Downstream Latency of 0 SHOULD be used if a specific Maximum Downstream Latency is not required.	Yes	SHOULD	
MMREQ15509	When the PDP is going to shutdown, it SHOULD send a COPS Client-Close message to the PEP.	No	SHOULD	
MMREQ15510	In the COPS Client-Close message, the PDP SHOULD NOT send the PDP redirect address object PDPRedirAddr.	No	SHOULD	
MMREQ15514	This field MAY be unspecified in which case the DSCP/TOS field in the packet is not over-written by the CMTS.	Yes	MAY	
MMREQ15515	This field MAY be used in both the upstream and downstream directions.	Yes	MAY	
MMREQ15516	A Classifier MAY have wild-carded fields (indicated by zeroed fields), but care must be taken so that multiple IP flows do not unintentionally match the same Classifier, which can lead to unexpected results.	Yes	MAY	
MMREQ15517	The Policy Server and Application Manager MAY specify a second set to represent the reserved envelope, and a third set to represent the committed envelope.	Yes	MAY	Optional - not used
MMREQ15519	Alternatively, the PS/AM MAY issue separate Gate-Set messages to tell the CMTS to authorize and reserve and then to commit via a subsequent Gate-Set message.	Yes	MAY	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15520	If the approximations do not give the Policy Server or Application Manager the control it desires, the PS/AM MAY use the other methods of defining the Traffic Profile, which includes the ability to define some DOCSIS-specific parameters.	Yes	MAY	
MMREQ15534	Application Managers that provide novel services MAY use the Configurable field to specify new session classes.	Yes	MAY	
MMREQ15537	The Application Manager or Policy Server MAY also query for this object as part of a failure recovery or other mechanism.	Yes	MAY	
MMREQ15538	The Opaque Data object contains information that a Policy Server or Application Manager MAY store on a CMTS that remains opaque to the CMTS.	Yes	MAY	
MMREQ15542	At this point, the PDP MAY periodically attempt to re-establish the connection.	Yes	MAY	
MMREQ15543	Messages that MAY be initiated by the Application Manager and Policy Server include Gate-Set, Gate-Info and Gate-Delete.	Yes	MAY	
MMREQ15546	The Gate-Set message MAY be sent by the PDP to the PEP to initialize or modify the operational parameters of a Gates.	Yes	MAY	
MMREQ15551	To modify the Traffic Profile associated with an existing Gate, an Application Manager MAY send a Gate-Set message with the GateID of the Gate to be modified and the new Traffic Profile.	Yes	MAY	

Table 12: PacketCable Requirements Compliance Matrix

REQ Tag	Requirement Text	Compliance	Category	Comment
MMREQ15552	To modify the Usage Limits associated with an existing Gate, an Application Manager MAY send a Gate-Set message with the GateID of the Gate to be modified.	Yes	MAY	
MMREQ15557	For applications that require a high-degree of time accuracy, the AM MAY query the CMTS for its Gate Time Info object after it moves a Gate into or out of a committed state.	Yes	MAY	Optional - not used
MMREQ15562	An Application Manager MAY provide an optional Event Generation Info object in a Gate-Set message.	Yes	MAY	Optional - not used
MMREQ15564	The Application Manager MAY specify a primary RKS IP address in the optional Event Generation Info object or the Application Manager MAY allow the Policy Server to use its default primary and secondary RKS IP Addresses.	Yes	MAY	Optional - not used
MMREQ15565	If the AM specifies a primary RKS IP Address, it MAY also specify a secondary RKS IP Address.	Yes	MAY	Optional - not used
MMREQ15566	In some situations, where the Application Manager and the Policy Server is acutely aware of DOCSIS, it MAY specify the Traffic Profile for the Gate using the DOCSIS Service Class Name or the DOCSIS-specific parameterization format.	Yes	MAY	
MMREQ15576	All envelopes used in a Traffic Profile MUST be the same type, i.e. either FlowSpec, DOCSIS Service Class Names, or DOCSIS-Specific Parameters.	Yes	MUST	

126.9 Glossary

Term	Definition
AM	Application Manager - logical network element defined in the PacketCable Multimedia architecture responsible for making bandwidth requests on behalf of a cable agnostic client.
Best effort	The default service flow. The characteristics for this service flow are defined in the cable modem config file. If a packet does not match any classifier then it is assigned to the best effort service flow.
CableLabs	A standards body that writes interface specifications and defines functional behavior for cable network elements.
Classifier	The set of parameters by which a media packet is judged to determine which service flow the packet belongs on.
Client	A SIP client
CM	Cable Modem - a cable network device that provides access to the cable network from an ethernet IP network.
CM	Call Manager - an MCS architecture component responsible for managing call-halves.
CMTS	Cable Modem Termination System - gateway between the cable HF/C network and the ethernet IP network. The CMTS receives the PCMM messages and communicates with the cable modem via DOCSIS to set up managed service flows.
COPS	Common Open Policy Service - a protocol defined in RFC 2748 that sets up a master/slave relationship between network elements for policy decisions. The PCMM protocol is an extension of COPS.
CS2M	CS2000 Management Tools - the CS2K GWC provisioning GUI
DOCSIS	Data Over Cable System Interface Specification - the protocol used between cable modems and their CMTS to set up service flows and classifiers.
DIFFSERV	Differentiated Services - an IP packet marking scheme that allows IP packets to be treated differently in the network
DSCP	DIFFSERV Code Point - the bit pattern used for DIFFSERV
GETS	Government Emergency Telephone Service - a telephony service that gives higher priority to some callers so that government services can function in the presence of extremely high call loads
HF/C	Hybrid-Fiber/Coax
IKE	Internet Key Exchange - used in PCMM to authenticate the PS from the AM
IPSec	IP Security - used in PCMM to secure the PCMM signaling between the AM and the PS (and between the PS and the CMTS)
KRS	Key Registration System
NAT	Network Address Translator - a device that translates between public network addresses and private network addresses.

Term	Definition
PacketCable	A subdivision of CableLabs that focuses on standards for VoIP over cable and multimedia over cable.
PC	Personal Computer (in this case)
PCMM	PacketCable Multimedia - an architecture and protocol for managing cable network bandwidth on behalf of cable agnostic clients.
PDP	Policy Decision Point - the COPS network element responsible for formulating network policy. The AM is a PDP. The PS is a PEP w.r.t. the AM and a PDP w.r.t. the CMTS.
PEP	Policy Enforcement Point - the COPS network element responsible for enforcing policies created by the PDP. The CMTS is a PEP. The PS is a PEP w.r.t. the AM and a PDP w.r.t. the CMTS.
Policy	A policy in the context of PCMM defines the access to and level of managed QoS available to a PCMM subscriber.
PS	Policy Server - network element defined in the PacketCable Multimedia architecture responsible for receiving PCMM signaling from and AM and forwarding it to the correct CMTS.
QoS	Quality of Service - the set of network characteristics that determine how a media packet is treated
SA	IPSec or IKE Secure Association
Service Flow	A managed QoS pipeline through the cable HF/C network defined by the quality of service given to the packets that transit the service flow.
SIP	Session Initiation Protocol - a VoIP signaling protocol
Socket	The IP address and port number used to communicate over an IP network to a particular service.
SS-L	Session Server Lines - a name for the MCS application server when used with CS2000
TOS	Type Of Service - a set of bits in the IP header that can be used to mark IP packets for different treatment in the network. Some of the TOS bits are used for DSCP.

127: Functional description (FN): A00011746

127.1 Feature name and Feature ID

A00011746: Addition of LGRP_TYPE field to GW profiles (Corrective)

127.2 Purpose

In SN08 the ability to define a GWs profile by creating an XML document (referred to as a certificate) was introduced. The SN08 certificate included all of the flexible fields that were available in SN08 for the most part. However, the ability of the core to define profiles was also made available in SN08. This core field was not included in a 1 to 1 relationship with the certificate, but rather was coupled with certificate field Endpoint_Type. Because of the difficulties of updating profiles when this core field is updated, a new field is introduced for SN09 into the CMT certificates that will define the Lgrp Type value that is sent to the core. Therefore, a direct relationship between core Lgrp types and a specific profile is made available by this enhancement.

127.3 Customer Facing Document Changes

A gateway certificate/profile captures a set of characteristics of a particular type of gateway. This set of characteristics can help us associate a gateway with the right type of gateway controller, manage the load balance of the gateway controller, and eventually achieve CallP purpose using the gateway.

This activity introduces a new optional field that is included in the profiles certificate. The LGRPType field is introduced and is used to drive “core” datafill for table LGRPINV. As suggested from the core table datafilled, LGRPINV, this field is only applicable for line gateways and is therefore optional in the XML document certificate. Even though this is an optional certificate field, this field is mandatory for all profiles that generate LGPRs.

In general, this field affects “core” behaviors applied to LGRPs. For a detailed discussion concerning core behavior driven by this field, refer to core NTP documentation.

128: Functional Description (FN) A00011827

128.1 Feature name and Feature ID

A00011827 - GWC Autonomous SWACT

128.2 Description

The objective of this feature is to provide an optional capability for Gateway Controllers (GWCs) to autonomously switch activity (SWACT) when communication has been lost with all associated media gateways. This functionality adds an additional layer of redundancy to the network in an attempt to reduce Call Processing outages during partial network failures.

128.2.1 Overview

The autonomous SWACT is an additional option provided to the customer for utilizing redundant network components. The autonomous SWACT functionality is on a GWC node basis and is only supported on GWCs supporting trunk and/or large line gateways. This option is provided as an attempt to automatically recover lost communication between the GWC and its associated media gateways. An autonomous SWACT of the GWC is by no means guaranteed to recover communication between the network components; however, it provides an additional mechanism for the customer to reduce outages and minimize the need for manual intervention.

An autonomous SWACT of a GWC is only performed after the provisioned timer expires, given that the timer is started after all associated media gateways, for that GWC, have been taken out of service by the GWC, and the messaging queues that notify the Core of the state transitions have been processed. The time period to wait before performing a SWACT is a provisionable value on a per GWC basis through the CMT GUI. The delay period helps to ensure the GWCs will not autonomously SWACT during brief network interruptions.

Prior to an autonomous SWACT, the GWC will verify that the inactive unit is in-service and capable of accepting activity. The GWC cannot guarantee connectivity to the gateways will be restored after the SWACT is performed. Depending on the location of the outage in the network, the SWACT may, or may not, restore connectivity.

After an autonomous SWACT, the newly active unit will not attempt another autonomous SWACT until communication has been restored to at least one gateway. Until communication can be verified between the GWC and at least one gateway, additional SWACTs will provide no appreciable benefit in recovering communication with the gateways.

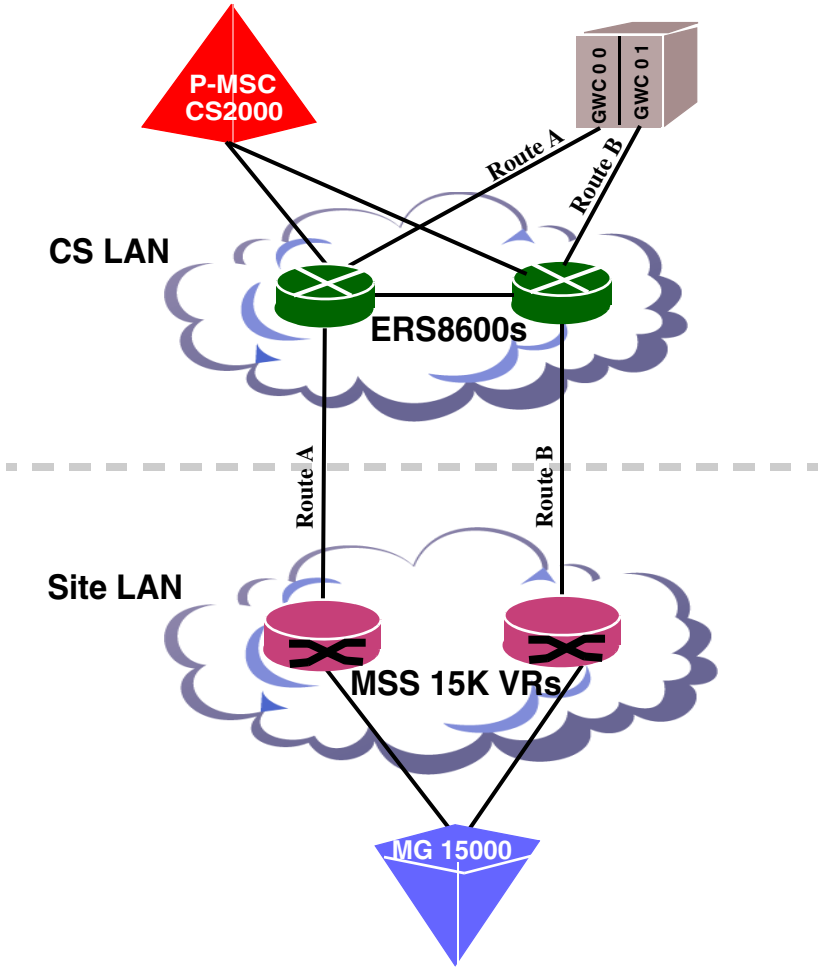
To assist the customer with identifying network failures, a critical alarm is raised in CMT when communication is lost with the GWC's associated gateways. A second critical alarm is raised when the autonomous SWACT has been initiated.

128.2.2 Network Topology

In certain network configurations, an autonomous SWACT may recover lost communication between the GWC and its associated media gateways.

In the following network diagram, each GWC unit is associated with a different MSS 15000 Virtual Router (MSS 15000 VR). In the event the MSS 15000 VR associated with the active unit encounters a network fault, a SWACT to the mate GWC unit will utilize the redundant path restoring communication between the GWC and the media gateway.

Figure 1 Network Configuration



128.2.3 Flow Diagram

The following diagram details the flow of control for the GWC autonomous SWACT functionality. In the flow diagram that follows, HB refers to heartbeat.

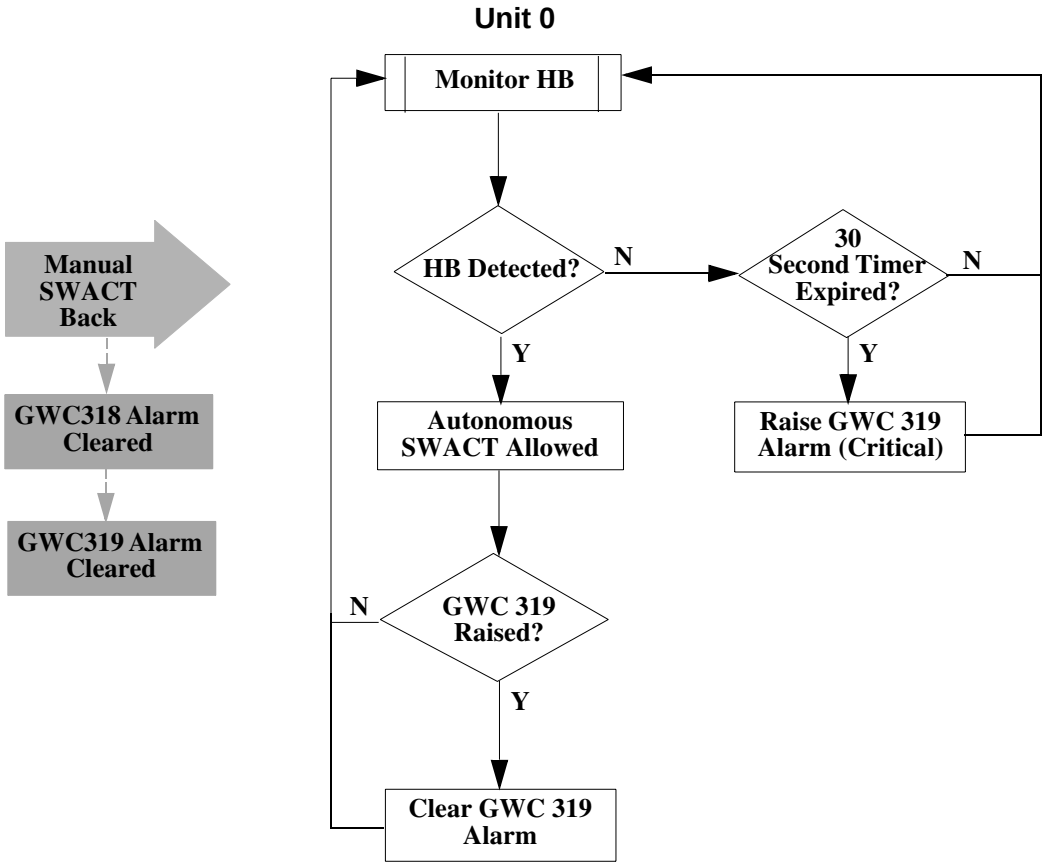
The following diagram shows the logic flow following a manual Warm SWACT back to the original active unit following an autonomous SWACT.



128.3 Autonomous SWACT Controls

128.3.1 GWC Safeguards

Safeguards have been added in the GWC to prevent

- an autonomous SWACT from occurring prior to an outage condition being cleared, and,
- to prevent an autonomous SWACT from being performed too soon after the system has recovered.

After the autonomous SWACT has completed, the newly active unit prevents a second autonomous SWACT from occurring until the previous condition has been cleared.

Once the condition is cleared, a ten (10) minute sanity timer is started. During this ten minute period autonomous SWACT requests are queued. When the sanity timer expires, the request is processed as normal.

Should the condition clear, either while the request is queued, or while the time delay is being processed, the request will be canceled and no SWACT will occur.

128.3.2 Manual SWACT Interactions

At no time are manual SWACT requests from the GWC element manager blocked due to the autonomous SWACT functionality. Manual SWACTs are processed regardless of the state of the autonomous SWACT functionality. Any pending autonomous SWACT requests are canceled when a manual SWACT is processed.

128.4 Call Management

The autonomous SWACT application performs a Warm SWACT to switch activity to the mate unit. The Warm SWACT permits stable calls to remain active over the SWACT for certain gateway and call types. The handling of calls over the SWACT is described in the following sections.

128.4.1 H.248 Trunk Gateways

128.4.1.1 ISUP and PRI Trunk Calls

Calls on ISUP and PRI trunks remain active on the Call Server when heartbeat is lost with the gateway. When the gateway is determined to be unresponsive, the gateway is taken out-of-service and trunks with stable calls are transitioned from the Call Processing Busy (CPB) state to the Call Processing Deload (CPD) state. Once communication is restored, trunks in the CPD state are transitioned back to the CPB state.

128.4.1.2 PTS Trunk Calls

PTS trunk calls do not survive when the gateway is taken out-of-service. When the gateway is determined to be unresponsive, and subsequently taken out-of-service, all calls are immediately released.

128.4.2 TGCP Trunk Gateways

TGCP trunk calls do not survive when the gateway is taken out-of-service. All calls on TGCP gateways are immediately released when the gateway is determined to be unresponsive and taken out-of-service.

128.4.3 Line Gateways

128.4.3.1 Large Line Gateways

Large line gateways may provide Emergency Standalone (ESA) capabilities. For such gateways, intra-switched calls survive when the gateway is taken out-of-service; however, all other calls are released when the gateway is taken out-of-service.

128.4.3.2 Small Line Gateways

The autonomous SWACT functionality is not supported for GWCs supporting small line gateways.

128.5 Provisioning

The autonomous SWACT functionality is provisionable on a per GWC node basis. When a GWC is added the functionality is disabled, which is the default state. The CMT GUI is used to enable, or disable, the functionality. The GUI also provides the ability to set the timer value. The timer value identifies the time to wait before performing the autonomous SWACT after the loss of communication has been identified.

Please refer to the Configuration section of this document for provisioning details.

128.6 Logs and Alarms

New CMT alarms and logs are generated to indicate actions taken by the autonomous SWACT activity. This section provides a brief description of the alarms and logs. Please refer to the Fault Management section of this document for complete details.

128.6.1 Alarms

Two new critical CMT alarms are created to supplement existing major alarms which are raised when communication is lost to a gateway. The new alarms identify these conditions:

- Communication with the GWC's associated gateways is down
- Autonomous SWACT initiated

The first alarm is raised if communication to the GWC's associated gateways is lost. This alarm is cleared when communication is detected with at least one associated gateway. It is also cleared when the GWC is manually or automatically SWACT and is raised again on the newly active unit if communication is still lost with all the associated gateways.

The second alarm is raised when an autonomous SWACT is initiated from the unit detecting the communication outage. This alarm indicates that the system has taken action to correct the problem. The alarm is cleared

- manually from the CMT interface, or
- when activity is switched back to the original unit.

Additional information on clearing this alarm manually may be found in the Configuration (CN) section of this document.

These alarms are raised in addition to the existing major alarms raised against each gateway that loses communication with the GWC. Individual gateway

alarms are raised prior to the SWACT and cleared as communication is restored to the gateways.

128.6.2 Customer Logs

Customer logs are generated for the raising and clearing of alarms. Please refer to the Fault Management section for a list of the supported logs.

128.7 Hardware Requirements or Dependencies

The autonomous SWACT activity does not require special hardware. The autonomous SWACT functionality is supported on the MCPN750, MCPN905, and ATCA platforms.

128.8 Software Requirements or Dependencies

The autonomous SWACT functionality is available for packetized voice solutions that utilize IP solutions (IP over GigE and AAL5) and ATM solutions (Voice over AAL2) with these products:

- MSC Server 1000
- MSC Server 2000
- CS 2000 (North American and International software loads)
- CS 2000 - Compact (North American and International software loads)

128.9 Limitations and restrictions

1. The capability to enable GWC autonomous SWACT is available on CMT for all GWCs but the GWC autonomous SWACT action can only occur on GWCs hosting trunk and/or large line gateways. This action can not occur on GWCs hosting audio servers or small line gateways.
2. The GWC cannot verify the autonomous SWACT will restore lost communication to the associated gateways prior to attempting the SWACT.

128.10 Interactions

None.

128.11 Use Cases

128.11.1 Network Outage, GWC SWACT Recovers Gateways

1. The loss of communication with a gateway is detected.
2. The gateway is taken out-of-service.
3. It is confirmed that all associated media gateways have lost communication with this GWC.

4. The critical alarm (GWC 319) is raised indicating communication with all associated media gateways has been lost.
5. It is confirmed that all messaging queues have completed processing.
6. The SWACT is delayed for the duration of the timer value provisioned in the CMT.
7. A critical alarm (GWC 318) is sent to CMT indicating a autonomous SWACT is being initiated.
8. A Warm SWACT is performed, clearing the GWC 319 alarm.
9. The newly active unit monitors for communication with the associated media gateways.
10. Communication with at least one gateway is detected.
11. A ten (10) minute sanity timer is started to prevent further autonomous SWACTs until the timer expires.
12. After the sanity timer expires, autonomous SWACTs are again permitted.

Note: If communication with all associated media gateways is lost while the sanity timer is running, a SWACT event is queued an processed upon expiration of the sanity timer. Should communication be restored while the event is still queued, the event is cancelled and no SWACT is performed.

128.11.2 Network Outage, GWC SWACT Delayed Recovery

1. The loss of communication with a gateway is detected.
2. The gateway is taken out-of-service.
3. It is confirmed that all associated media gateways have lost communication with this GWC.
4. The critical alarm (GWC 319) is raised indicating communication with all associated media gateways has been lost.
5. It is confirmed that all messaging queues have completed processing.
6. The SWACT is delayed for the duration of the timer value provisioned in the CMT.
7. A critical alarm (GWC 318) is sent to CMT indicating a autonomous SWACT is being initiated.
8. A Warm SWACT is performed, clearing the GWC 319 alarm.

9. The newly active unit monitors for communication with the associated media gateways.
10. No communication is detected after thirty (30) seconds.
11. The critical alarm, GWC 319, is raised indicating communication with all associated media gateways has not been recovered.
12. The GWC continues to monitor for heartbeat from associated media gateways.
13. Communication with at least one media gateway is detected.
14. The GWC 319 alarm is cleared.
15. A ten (10) minute sanity timer is started to prevent further autonomous SWACTs until the timer expires.
16. After the sanity timer expires, autonomous SWACTs are again permitted.

Note: If communication with all associated media gateways is lost while the sanity timer is running, a SWACT event is queued an processed upon expiration of the sanity timer. Should communication be restored while the event is still queued, the event is cancelled and no SWACT is performed.

128.11.3 Manual Warm SWACT back to the original GWC unit when Communication has not been restored with an Autonomous SWACT

1. The loss of communication with a gateway is detected.
2. The gateway is taken out-of-service.
3. It is confirmed that all associated media gateways have lost communication with this GWC.
4. The critical alarm (GWC 319) is raised indicating communication with all associated media gateways has been lost.
5. It is confirmed that all messaging queues have completed processing.
6. The SWACT is delayed for the duration of the timer value provisioned in the CMT.
7. A critical alarm (GWC 318) is sent to CMT indicating a autonomous SWACT is being initiated.
8. A Warm SWACT is performed, clearing the GWC 319 alarm.

9. The newly active unit monitors for communication with the associated media gateways.
10. No communication is detected after thirty (30) seconds.
11. The critical alarm, GWC 319, is raised indicating communication with all associated media gateways has not been recovered.
12. A manual Warm SWACT is performed from the CMT
13. Both the GWC 318 and GWC 319 alarms are cleared
14. The newly active unit monitors for communication with the associated media gateways.
15. No communication is detected after thirty (30) seconds.
16. The critical alarm, GWC 319, is raised indicating communication with all associated media gateways has not been recovered.
17. The GWC continues to monitor for heartbeat from associated media gateways.
18. Communication with at least one media gateway is detected.
19. The GWC 319 alarm is cleared.

128: Functional Description (FN) A00012001

128.1 Feature name and Feature ID

A00012001 - IEMS Call Server 2000 SIP Integration

128.2 SN07/SN08 Background

In SN07&8, IEMS manages the Multimedia Communication Server Manager (MCS Manager). The MCS Manager when added can have as its managing type either an MCS/CSE MX NE or Media Proxy NE. When an MCS Manager is added to they IEMS, the MCS/CSE MX NE or Media Proxy NE is added as a map symbol under the Network Elements. The MCS System Manager is added as an element in the Element Managers map.

Along with the configuration of the MCS device was the ability to associate Fault Performance Managers, FPM's, to an MCS device which would be another input for faults and performance data for IEMS.

There were provisions for fault, performance, and configuration management of MCS and FPM devices.

The current existing MCS device functionality along with the RTP Media Proxy and FPM will continue to be supported in SN09.

To see more information concerning the addition of the MCS device in SN08, please see document SN08 A00007346 - Backward Compatibility Functional Specification at :http://livelink.us.nortel.com/livelink/livelink.exe?func=ll&objId=7485824&objAction=browse&sort=name

128.3 Main work Items

One of the first items is branding name changes for both the NGSS and MCS. The existing NGSS managed object to align with the Call Server 2000 Session Server. The Trunks version is relabelled to SSTrunks. The MCS SIP lines which is now deployed on a Linux platform will be relabelled SSLines.

The MCS configuration and management remains the same from SN08 to SN09. The Icon for the MCS on the Solaris platform for the NE will be modified to MC52 and the tree name will be changed from MCS/CSE to MCS5200. Also, a change is made in the configuration of the MCS Mgr as an EM with a type from Media *Proxy* to Media *Portal.*

Integrating the management of the fault and performance interfaces of the new SSLines platform, Langley hardware running Linux OS. The SSLines system will also have the ability to configure the Session Manager platforms

associated with the System Manager EM. There will also need to be configuration of the Provisioning Client servers. The configuration of the Session Managers will allow SSH launch to each Session Manager. The configuration of the Provisioning Client servers will allow the client to launch the MCS Provisioning Client.

Another work item consists of proxying all GUI/CLUI launches through the IEMS. The GUI/CLUI's that require proxying consist of:

1 MCS System Manager Console

2 Provisioning GUI

3 SSH to each platform associated with the SSLines deployment

The SSLines Element Manager and Network Element will provide and support all the existing functionality of the MCS/RTP Media Portal functionality pertaining to Fault Management, Performance collection, and device change management. There will however only be the option of being able to add the SSLines device as an SSLines Manager without the ability to configure the SSLines device as an RTP Media Portal. Also in SN09, the SSLines device will not be supporting FPM's.

To configure performance collection jobs, please refer to the SN08 document concerning MCS, http://livelink.us.nortel.com/livelink/livelink.exe?func=ll&objId=7485824&objAction=browse&sort=name

128.4 Existing functionality

As specified previously this activity is for rebranding and proxying the MCS GUI's through the IEMS. The functionality of handling faults and provisioning data remains unchanged.

The change, and deletion of an SSLines type device has remained the same except for the type being deleted or changed.

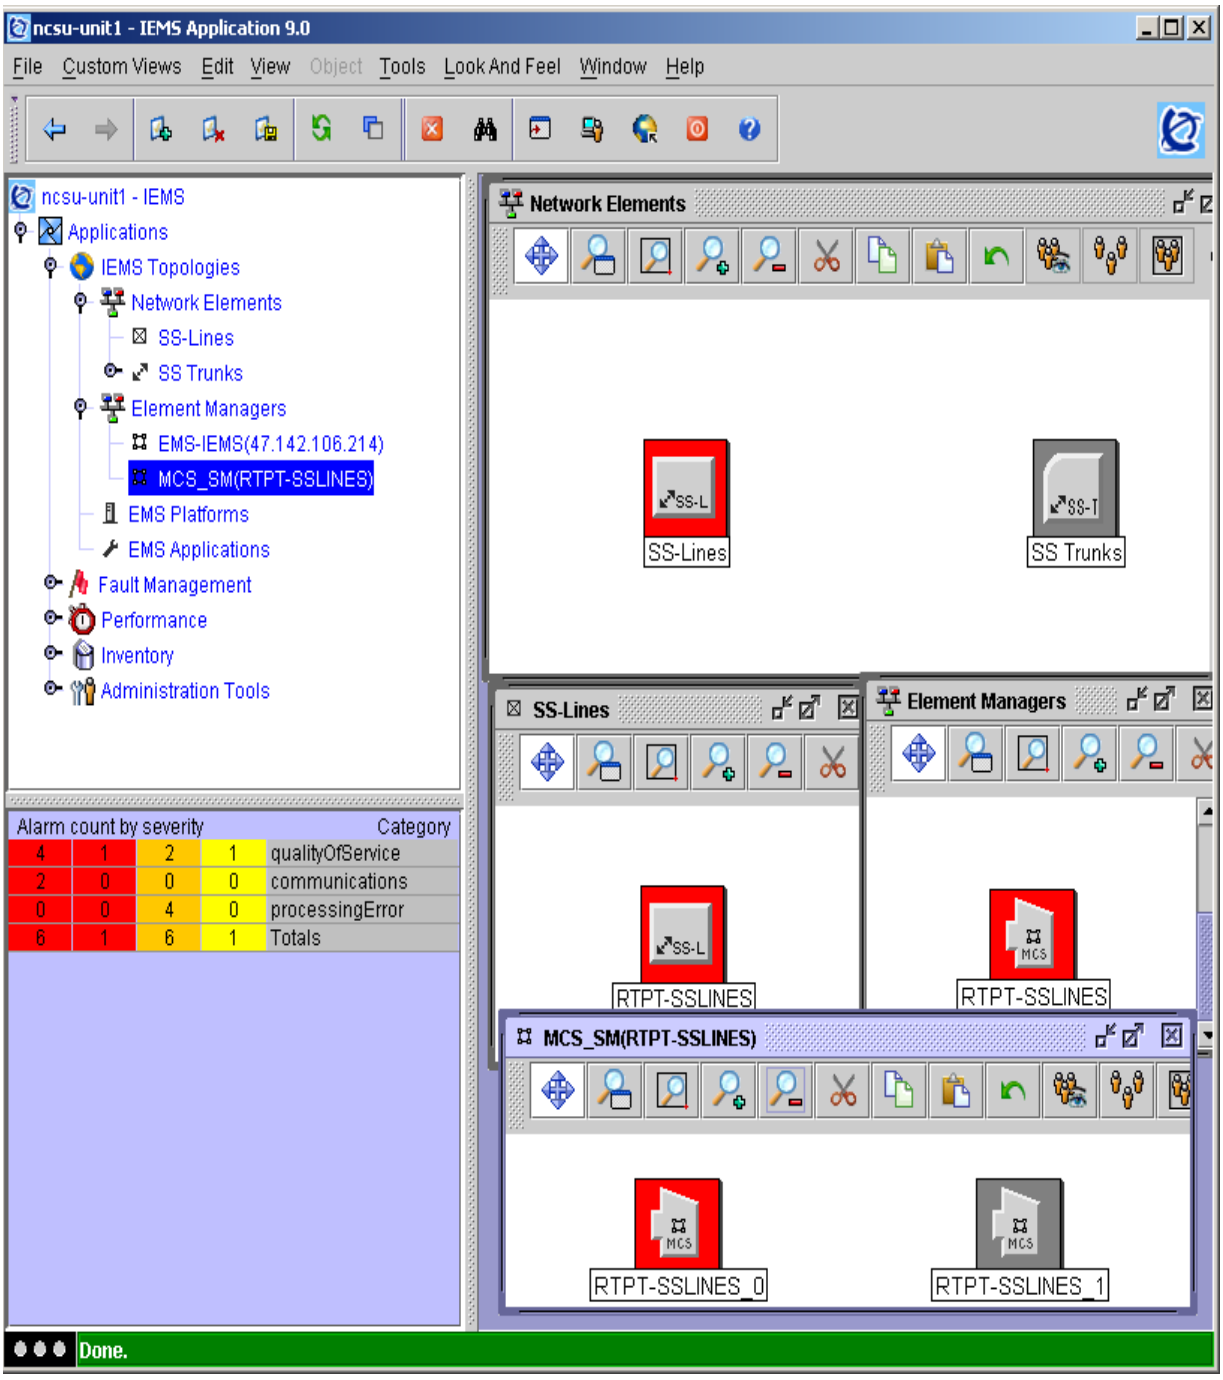
128.5 Changed Functionality

First and foremost is the branding change. When adding the SSLines device, an SSLines Mgr is added instead of an MCS Mgr or RTP Media Portal. The same information is entered concerning IP addresses, userid's, SNMP information, and performance data collection.

128.5.1 Topology

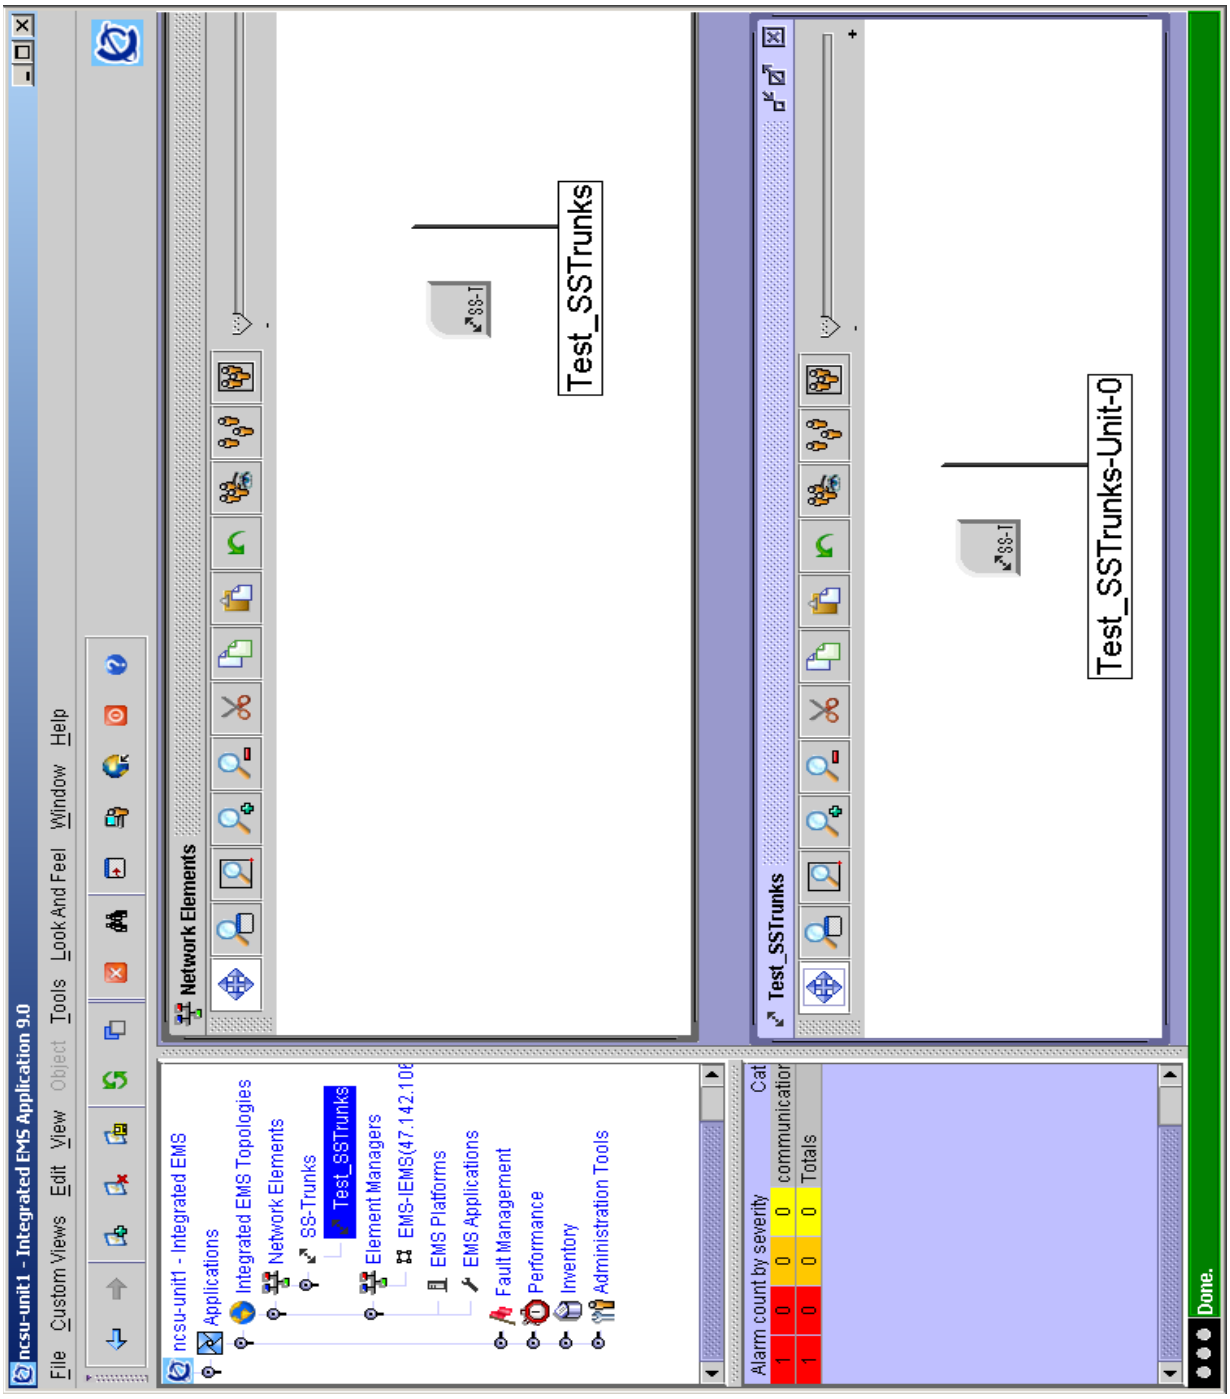
The topology of an SSLines as added into IEMS is displayed is in the same hierarchy as the existing SN08 MCS. The following screen shot shows the new branding and topology for the SN09 SSLines.

Figure 1 Topology of SSLines EM and NE



The SS Trunks topology will be similar to that of the Session Server and will be displayed as follows in SN09.

Figure 2 Topology of SS Trunks NE



128.5.2 Launch of applications

The launch of a command line has been modified in that it is now possible to launch a command line to any platform that is configured. When launch

command line is selected, a new frame will be displayed which will allow the user to select the platform to launch a command line to.

The launch of the command line for the System Manager and Session managers can be done from any of the maps in the GUI except from the Network Elements screen.

Figure 3 Launch of Command line From SSLines

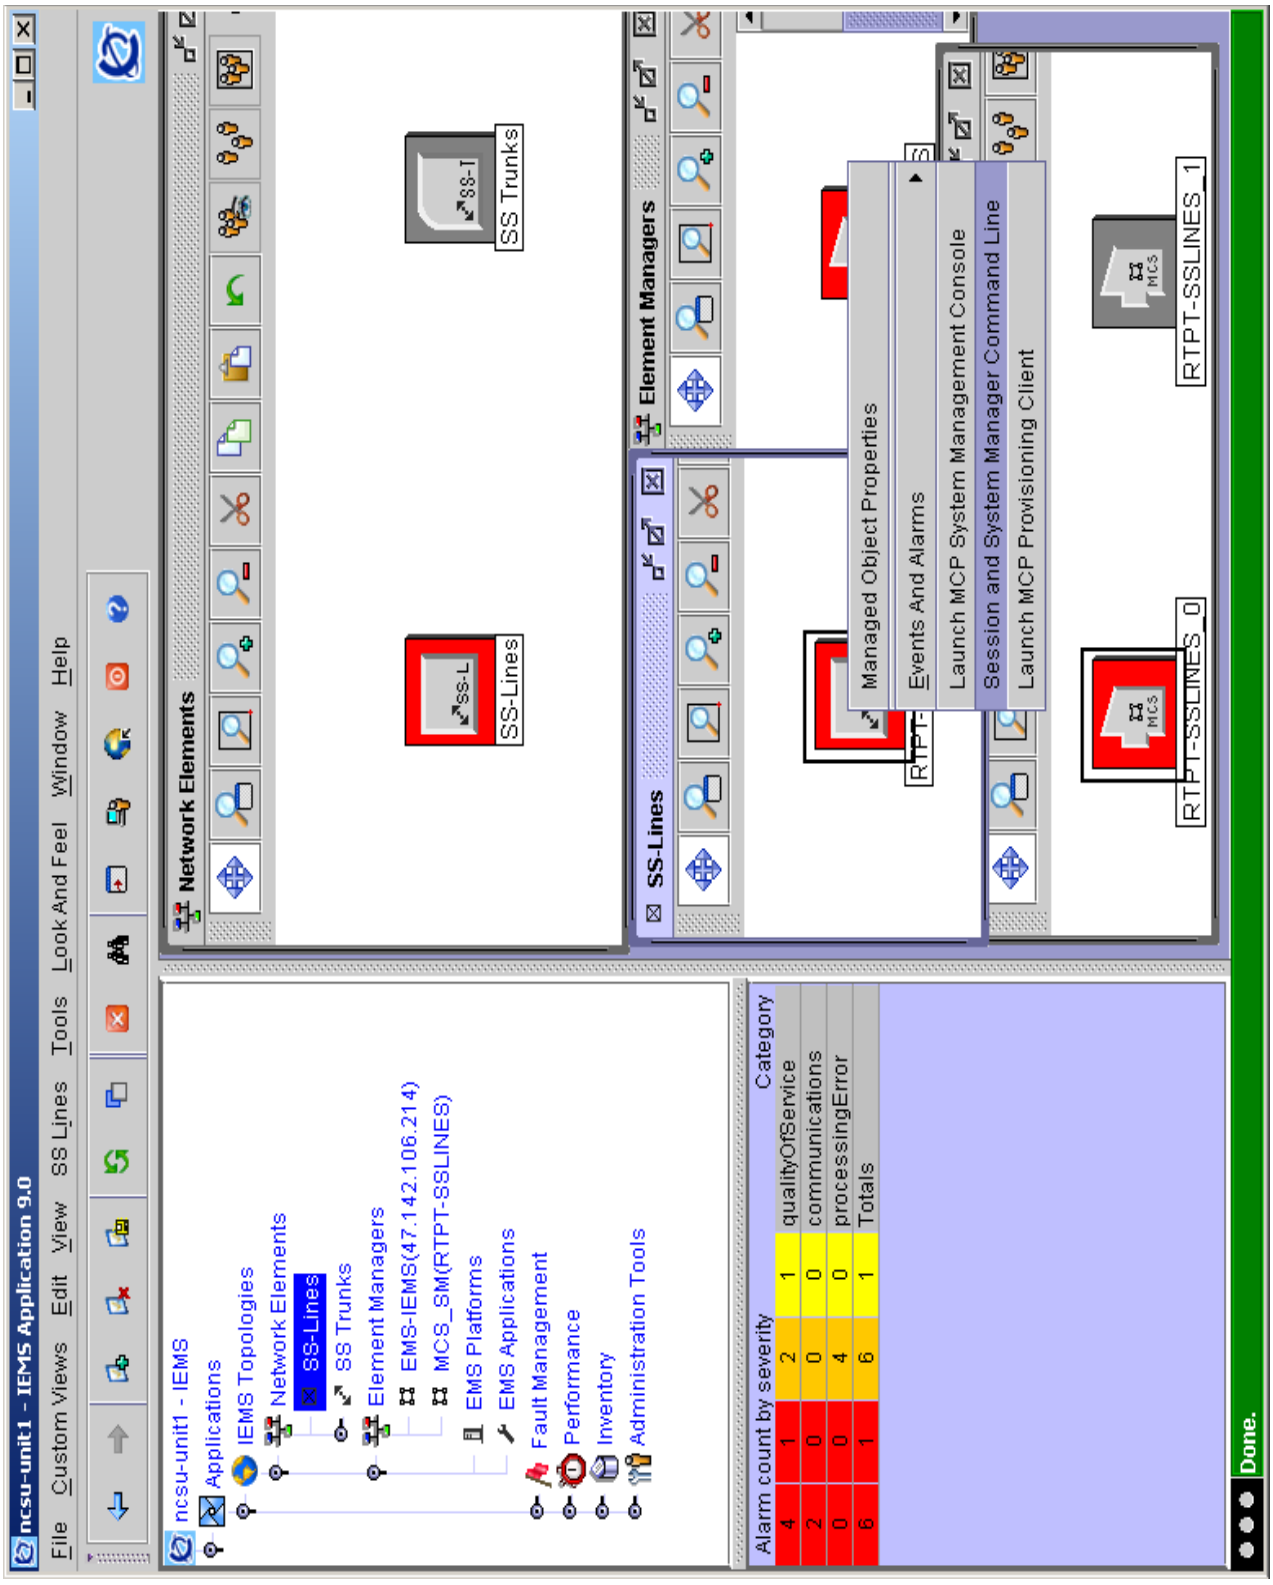


Figure 4 Launch of SSH command line to platform

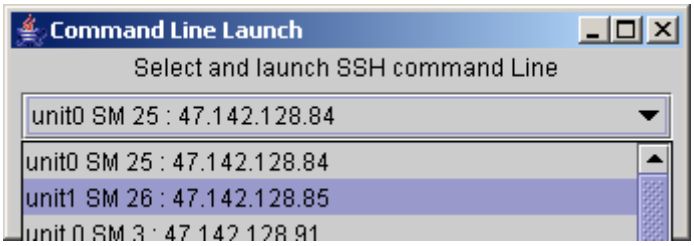

The drop down box will allow the user to choose any of the platforms that SSH can be launched to. The SSH connections will be proxied via the IEMS server.There will be a new option aganst the EM to configure the platforms which will allow the user to configure these platforms.

128.6 New Functionality

128.6.1 GUI

For SN08, it was only possible to configure the platform(s) associated with the System Manager associated with an MCS or RTP Media Portal. In SN09, it is possible to configure all the platforms associated with an MCS/SSLines deployment including the IP addresses of

1 The Provisioning Clients (two IP addresses)

2 The Session Manager platform IP addresses (up to three pairs)

This configuration is done from the map reference of the SSLines EM.

From the EM or NE it is possible to launch the Provisioning client GUI.

Figure 5 Launch of Provisioning Client from EM Map

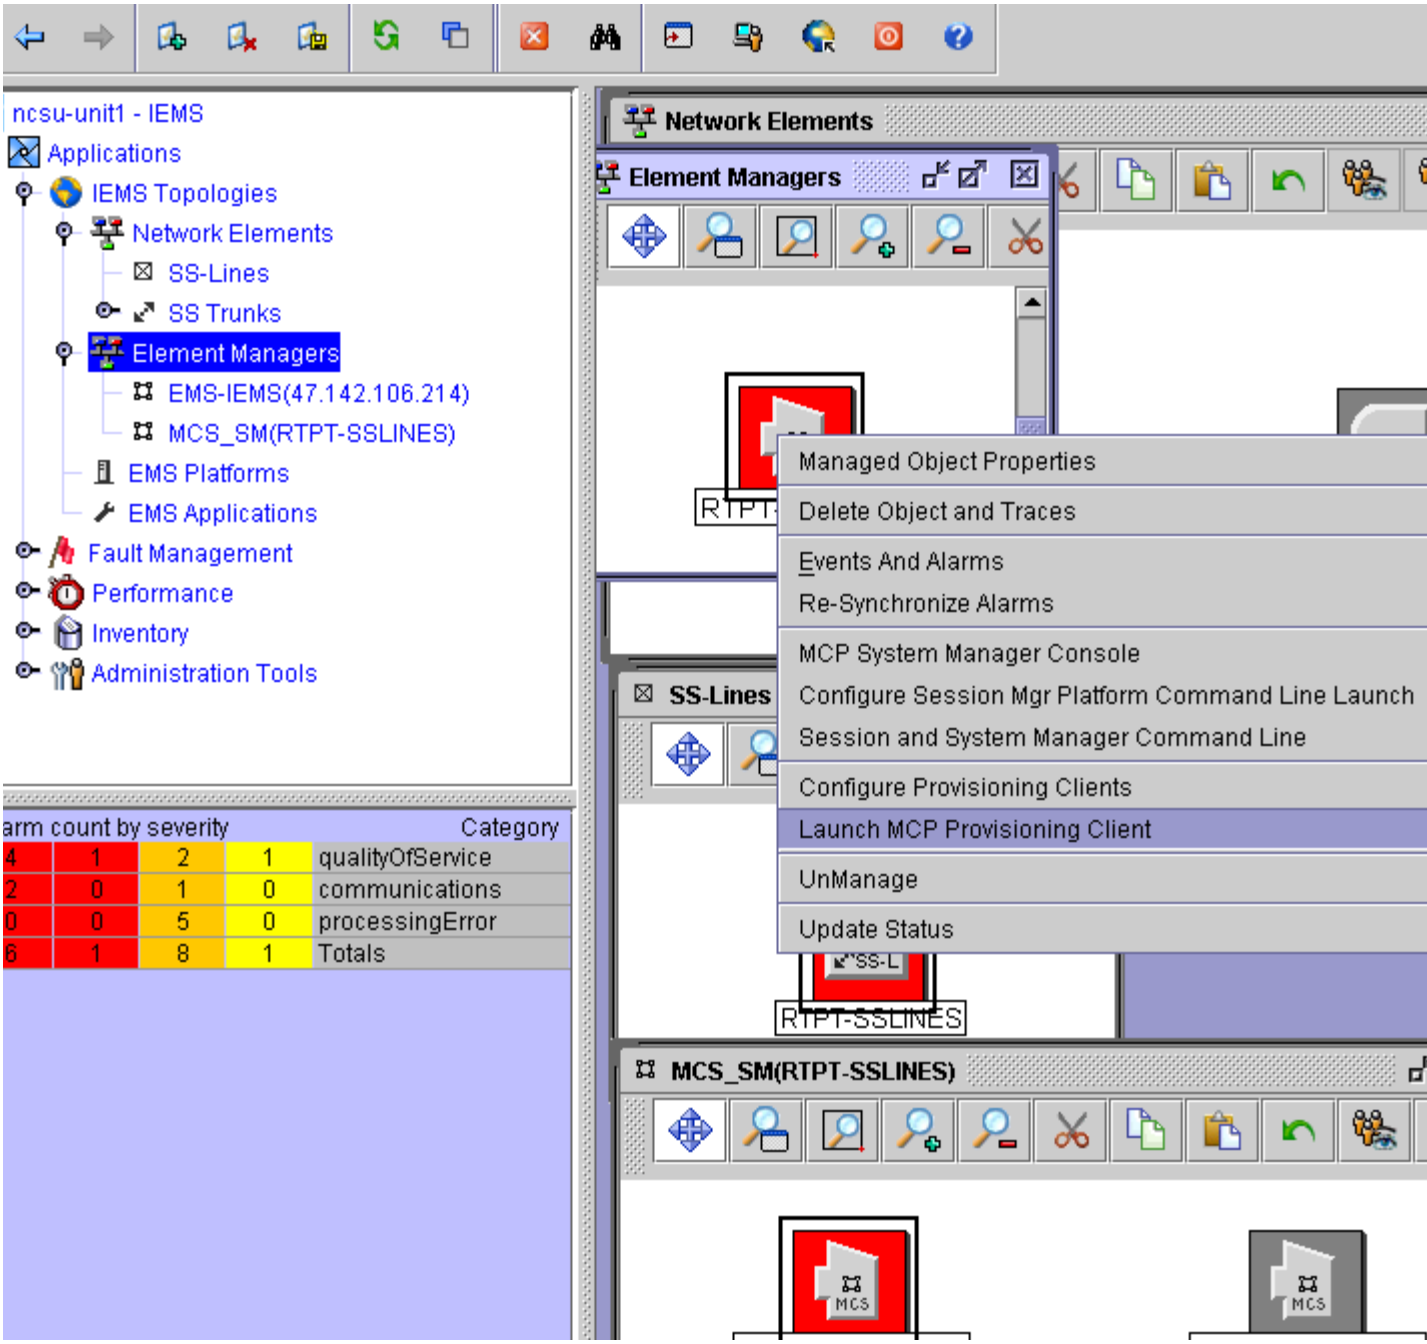

Figure 6 Launch from SSLines Element Manager Map

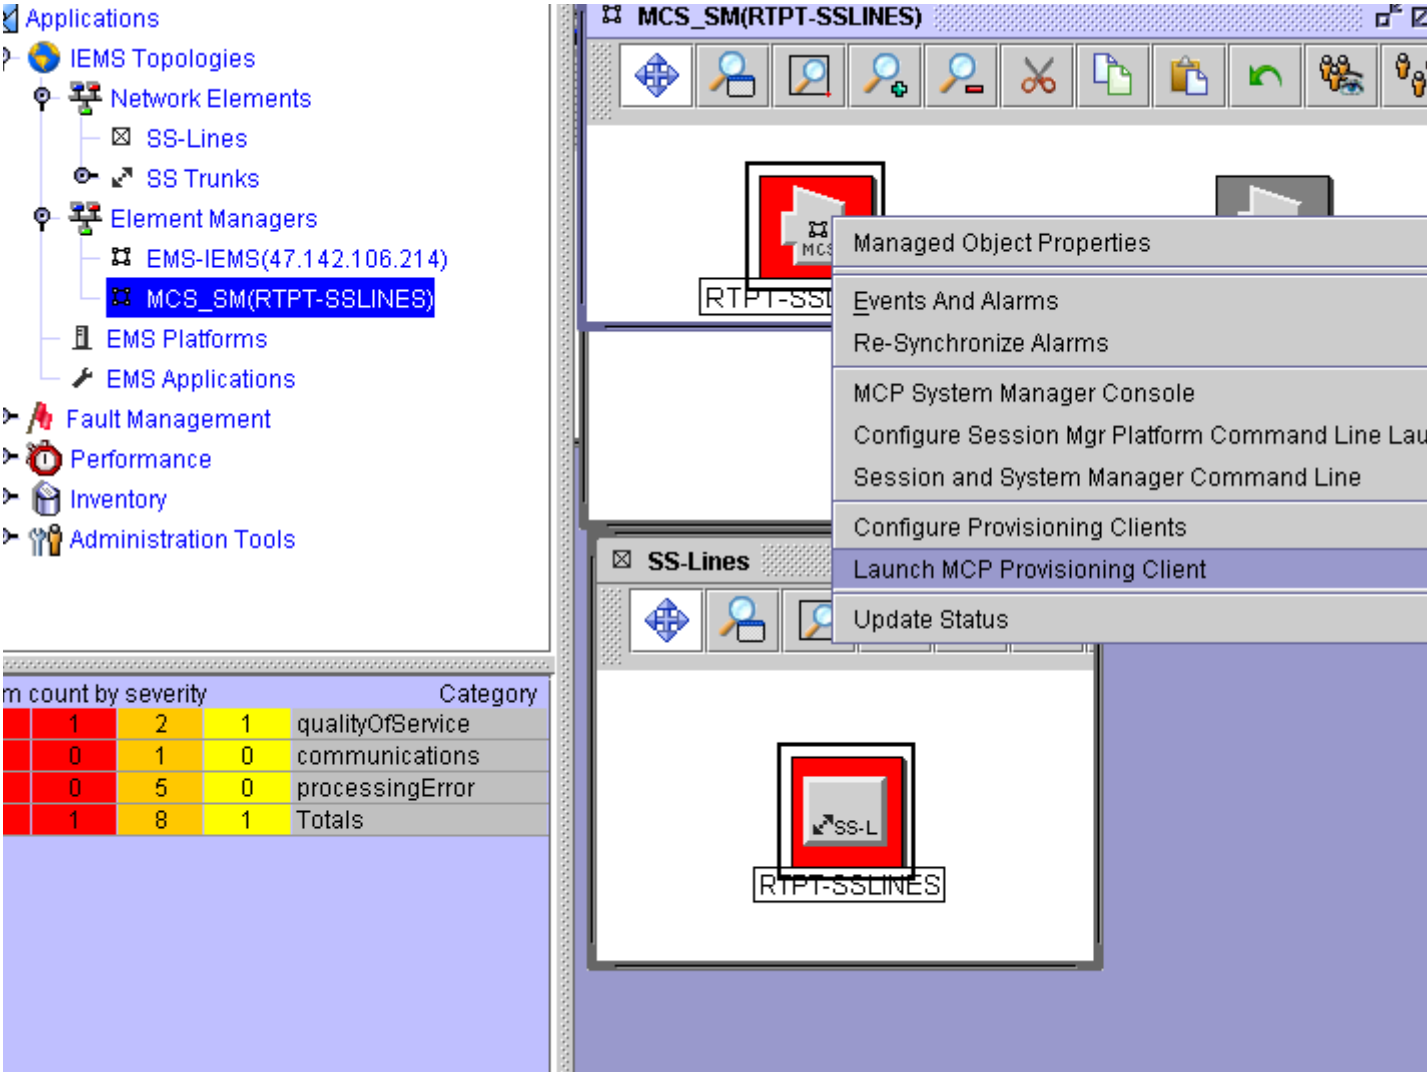

Figure 7 Launch of Provisioning Client from SSLines NE Map

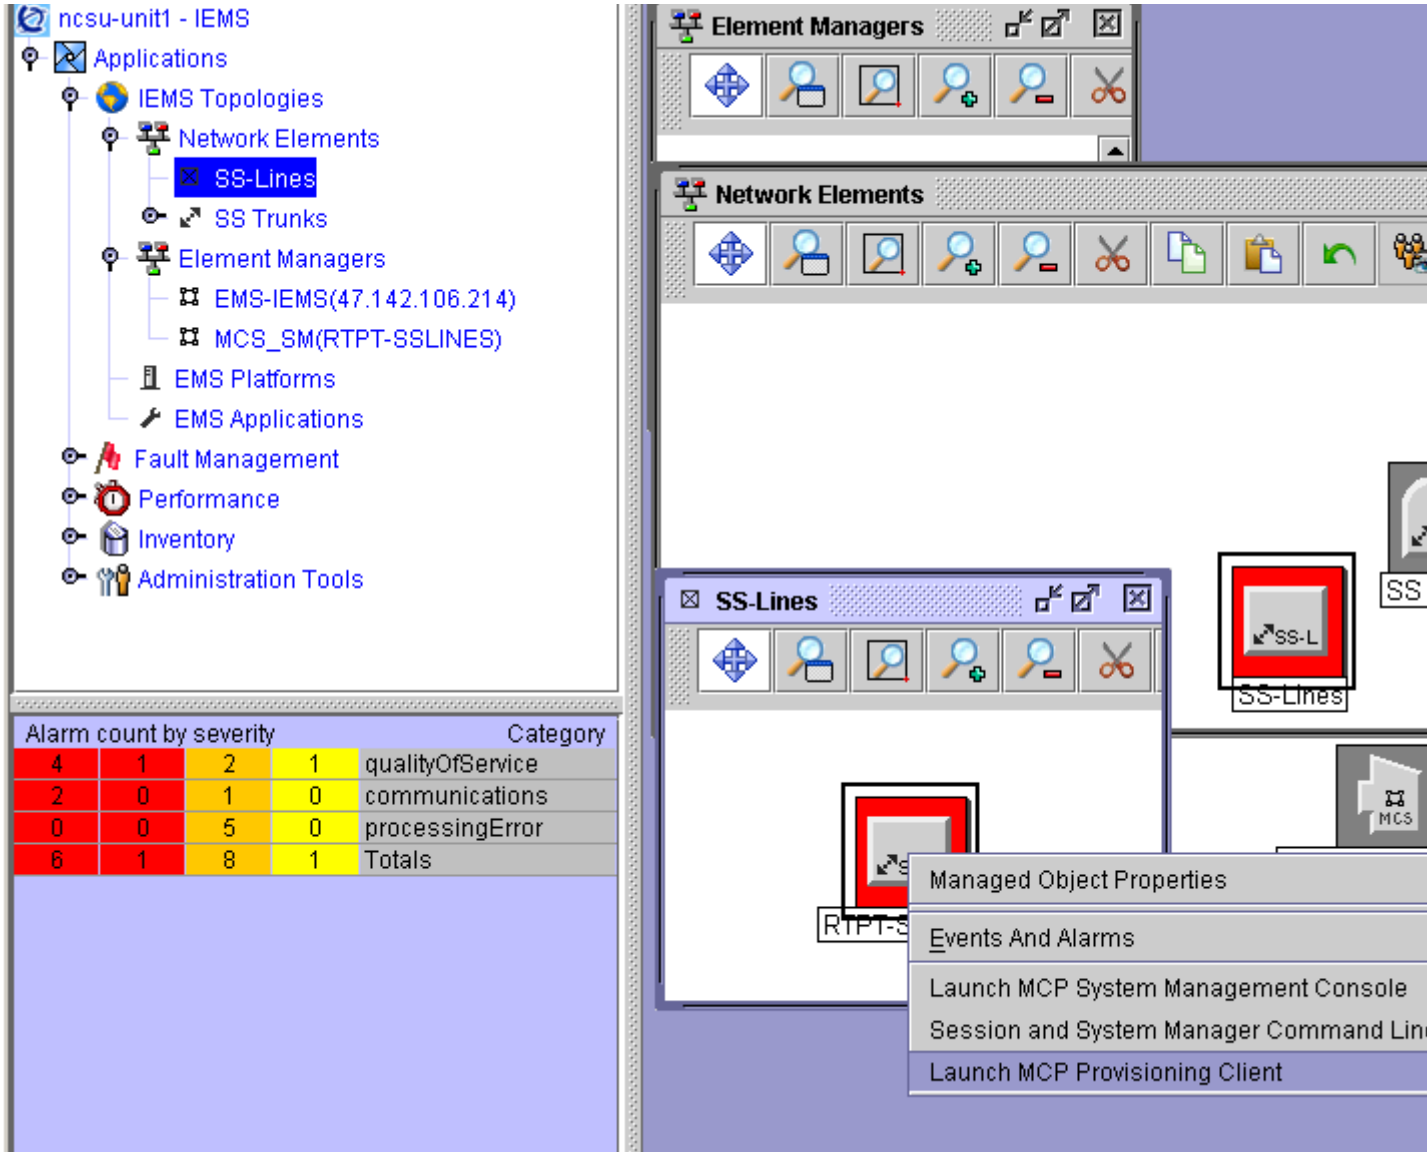
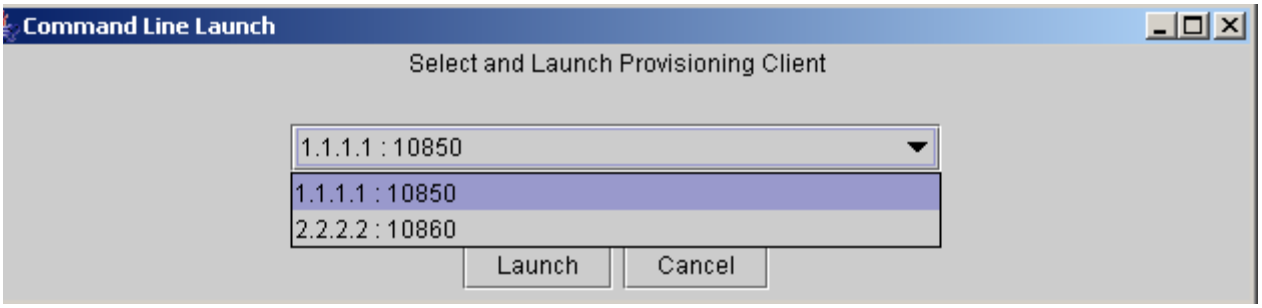


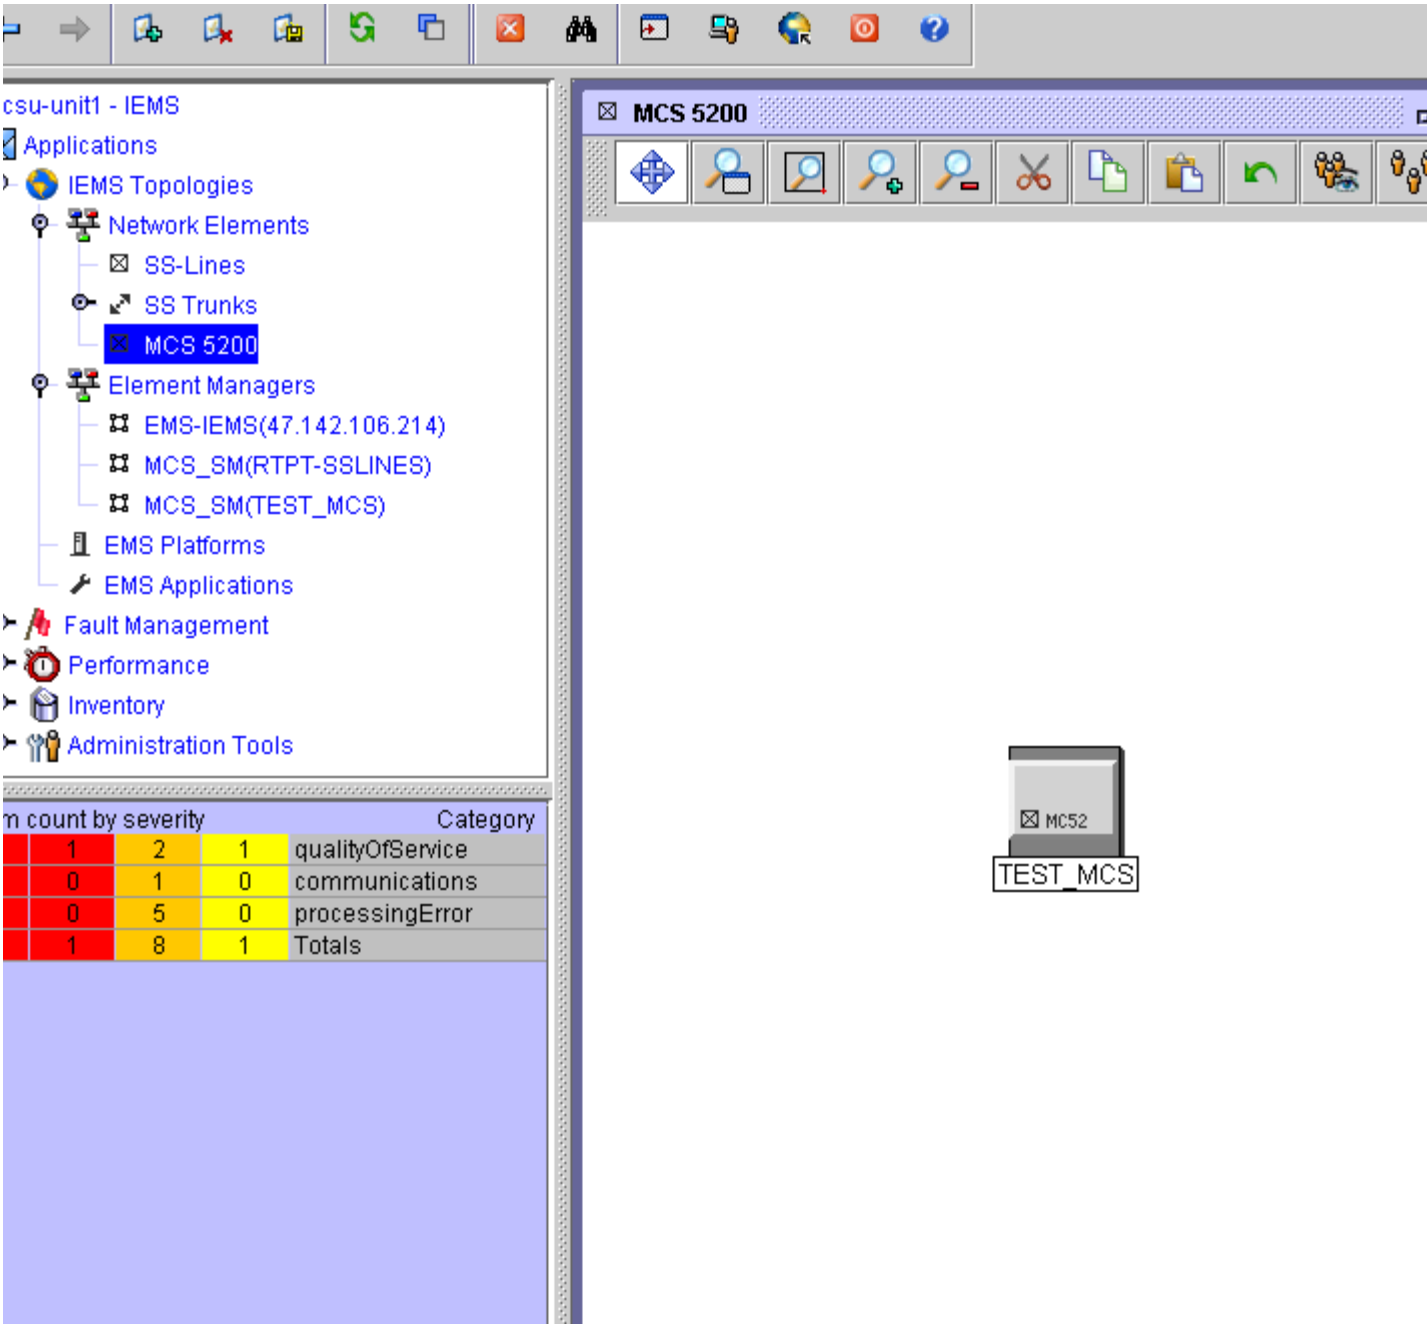
In all cases of lauching the Provisioning Client, there will be a combo dialog displayed which will have the user choose which platform to launch the Provisioning Client to as following.

Figure 8 Provisioning Client Launch



The Topology is changed somewhat for the MCS as an MCS/CSE device in the tree display to the following.

Figure 9 MCS MCS/CSE rebranded to MCS 5200



128.6.2 Proxy of MCS system manager and Provisioning client

As mentioned earlier, the MCS system manager console and provisioing cleint will be launched via the HTTP proxy. Both GUIs communicate with their servers via HTTPS. The apache proxy must be configured using the SSPFS CLI command. These details will be specified in the CN section.

No new ports will need to be opened on the firewall for this component.

128.7 Upgrade Considerations

128.7.1 Upgrade

For an upgrade the SSLines and SSTrunks configuration will be stored in the Oracle database as well as the faults and performance data and will be handled with the database upgrade.

128.7.2 Downgrade

For an upgrade the SSLines and SSTrunks configuration will be stored in the Oracle database as well as the faults and performance data and will be handled with the database downgrade.

128.8 Security

N/A

128.9 Hardware Requirements or Dependencies

This feature requires the SIP Lines componenets to reside on the Langley Linux platform.

128.10 Software Requirements or Dependencies

This will require an SN09 or later version of SSPFS.

128.11 Limitations and restrictions

Log streaming and bulk import and export will not be supported for the proxied system manager launch (see “128.6.2 Proxy of MCS system manager and Provisioning client”).

128.12 Interactions

N/A.

128.13 Glossary

Term	Description
IEMS	Integrated Element Management System

129: Functional Description (FN) A00012109

129.1 Feature name and Feature ID

A00012109 - Session Server Shared Library Replacement (SLR) Patching

129.2 Description

This activity enables Shared Library Replacement (SLR) patching for the SIP Trunking application on the NGSS.

The Unified Software Management (USM[1]) Patch manager application running on the Session Server will be used to download and apply/remove/query patches on the Session Server. USM is also responsible for pushing Inform Lists from the Session Server to an appropriately configured location.

Figure 1 provides a broad overview of the general patching process for Session Server.

Figure 2 provides a more detailed illustration of the steps involved in the Patch Creation process.

> ***Note:*** This feature is only responsible for the SLR patching functionality on the SessionServer. Other information provided here related to patch creation, downloading, and general patching, etc...on the Session Server is provided here for informational purposes only and is not a function of this specific feature.

[1]The USM functionary is part of the Siren program. USM provides a number of capability; however, the Session Server is only making use of the patch management functionality. Detailed information on USM patch management capabilities can be found in A00009264 - SIREN Installation and Patching.

Figure 1 Session Server Patching Process

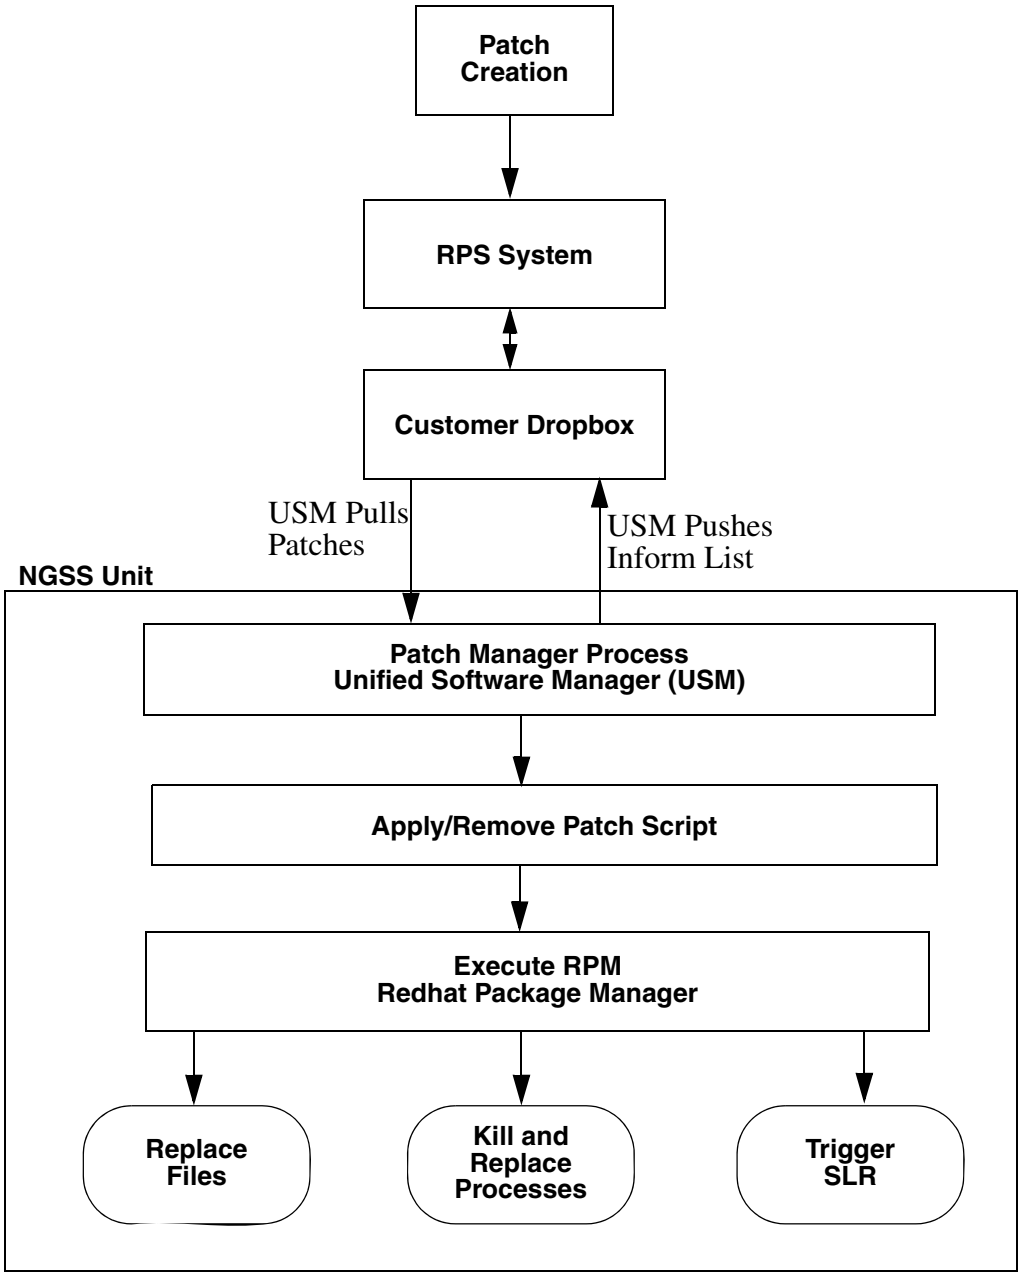


Figure 2 Session Server Patch Creation Process

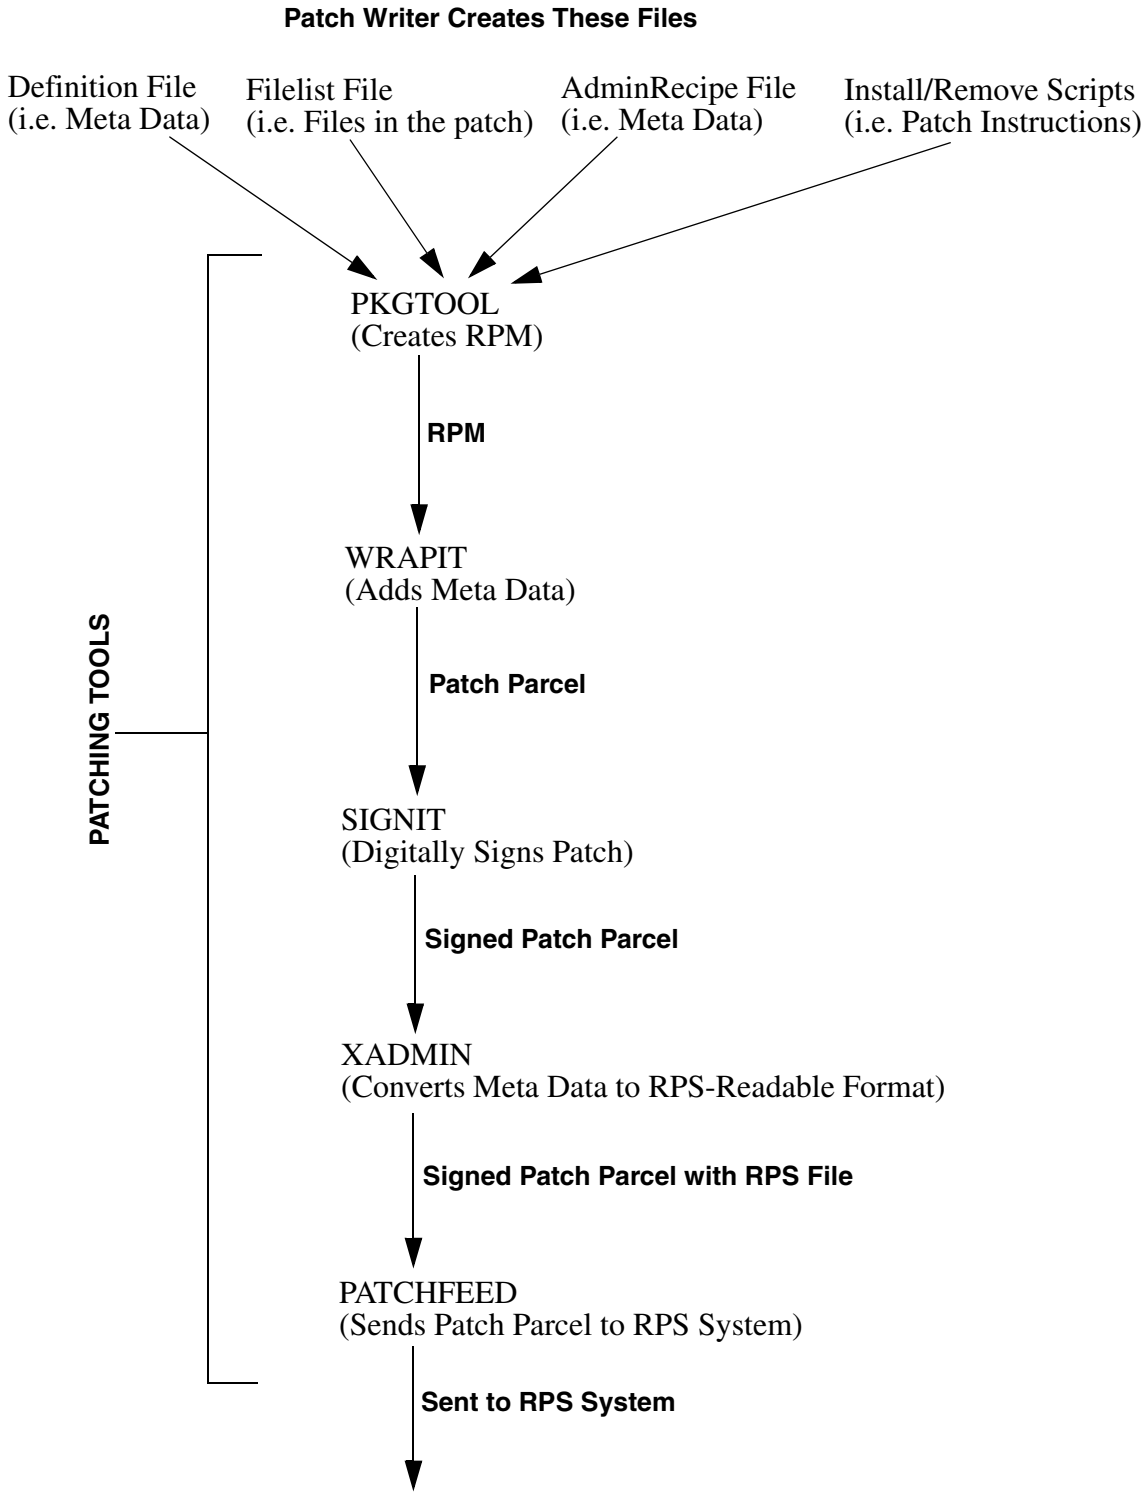

During patch creation a few files are called by the patching too (***pkgtool***)l to perform the actual tasks required to apply the patch and to include necessary patch administration information as part of the patch. These files are discussed here briefly.

- Filelist.pkg

  The filelist file defines which elements should be included with your software package. For example, this is where the patch writer defines which files are to be replaced on the Session Server, and the directory path of those files in both the Clearcase view and within the Session Server.

- Definition.pkg

  The definition file defines information describing the package such as name, version, prerequisites, description. These items are defined via XML Tags. There are over 40 possible tags - although only those designated as pertinent to the particular application need to be filled in. The only tags currently being used out of the Definition.pkg at the time of this writing are the pkg_summary and pkg_description. Output from this file is used to populate fields in the RPM.

- AdminRecipeFile

  This file, similar to the definition.pkg file, consists of tags. These tags are used to populate the adminfile that results from a patch build. All of the documented tags can be used in this file and will result in adminfile entries. Again, only those deemed applicable need to be populated.

  The pkgtool builds RPM packages based on filelist.pkg and definition.pkg files. The wrapit tool metadata wraps the RPM packages produced by pkgtool. Wrapit will default the metadata fields unless there is an admindata recipe file that overrides the defaults.

- Install, Remove scripts

  Next come the install and remove scripts. These files define the action that will occur when the patch is applied or removed.

129.1 Hardware Requirements or Dependencies

Not applicable.

129.2 Software Requirements or Dependencies

Session Sever SLR patching is available in SN09 drop 2.

129.3 Limitations and restrictions

Please note the following:

- The SLR capability provided by this feature only addresses the Session Server Trunk (SST) application.
- This feature does not address SLR patching for NCGL

- This feature does not address SLR patching for SPC.
- Figure 1 on page 1270 lists the Session Server components that are SLR patchable (i.e., hitless).

Table 1 Session Server Software Component Patchability

Component	Patching Method	SLR/ Hitless	Comments
HTML files and scripts (e.g. database upgrade scripts)	Simple file replacement	Yes	None.
JSP files used in OAMP interface	File replacement, followed by stopping and restarting Tomcat servlet container	Yes	Web access for the OAMP interface is temporarily inaccessible during the patch application. Users will get an error when trying to access a web page during this window. Call processing is not affected.
Solid database	Kill and replace	Yes	In this case, the version of the Solid database is being changed on the Session Server. The previous version of the database is killed and the new version supplied in the patch is started. During this kill and replace window, web access to the provisioning pages is temporarily unavailable and users will receive an error message if they attempt to access those pages while the patch is being applied. Call processing is not affected since all provisioning data is cached in the application at startup and the database does not need to be accessed during call processing. Note the database watchdog process must be stopped before replacing the Solid database to prevent a swact.
Web Server	Kill and replace	Yes	In this case, the version of the onboard web server is being changed on the Session Server. Access to the OAMP interface through the web is temporarily unavailable during the patch. Call processing is not affected.
Miscellaneous auxiliary processes (e.g. database watchdog process, SCP NCAS server process, SCPLite process, app mtc)	Kill and replace	Yes	Any process that can be stopped, replaced, and restarted in a patch without affecting call processing or causing a swact falls in this category. Currently this category includes the process that monitors the health of the Solid database and the process used for Non-Call Associated Signalling (NCAS) between the DMS core and the Session Server.
SPC Application (Session Policy Controller)	Kill and replace on inactive unit, swact, and then kill and replace on newly inactive unit	No	Patching any part of the SPC application currently requires the entire executable to be replaced. This means that the executable must be stopped before it can be replaced and thus these patches cannot be done in a hitless manner.

Table 1 Session Server Software Component Patchability

Component	Patching Method	SLR/ Hitless	Comments
3rd Party RadVision software used in SIP application	Kill and replace on inactive unit, swact, and then kill and replace on newly inactive unit	No	If a new version of the RadVision stack must be patched in or if specific bug fixes are required in the Radvision code for the SIP application, the patch cannot be done in a hitless manner.
Adding new OM (Operational Measurements) registers or groups to the SIP application	Kill and replace on inactive unit, swact, and then kill and replace on newly inactive unit	No	Note that existing OM registers can be pegged in new places in the SIP application in a hitless patch, but new registers or groups cannot be added without requiring a swact. To lessen the impact of this restriction, this activity will add placeholders for new OM groups and new registers within existing OM groups so that these “spare” OM structures could be used in a hitless patch.
SIP application process (except for RadVision code and new OMs)	SIP shared library replacement (SLR)	Yes	The vast majority of patches fall in this category since it covers all call processing fixes for the SIP application, except for the RadVision code and new OMs. Global data structures within the SIP application cannot be changed with an Session Server SLR patch, but this activity will add placeholders for new data that could be used in a patch. If these placeholders are not sufficient for a particular patch, then a kill and replace with swact patch is required or the functionality could be delivered in an MR.

129.4 Interactions

None known at this time.

129.5 Operational Measurements

This activity adds spare OM registers and spare OM groups for use by the SIPGW application. Refer to the Performance section for details.

USM	Unified Software Management

130: Functional Description (FN) A00012183

130.1 Feature name and Feature ID

A00012183 - Public Key Manager

130.2 Description

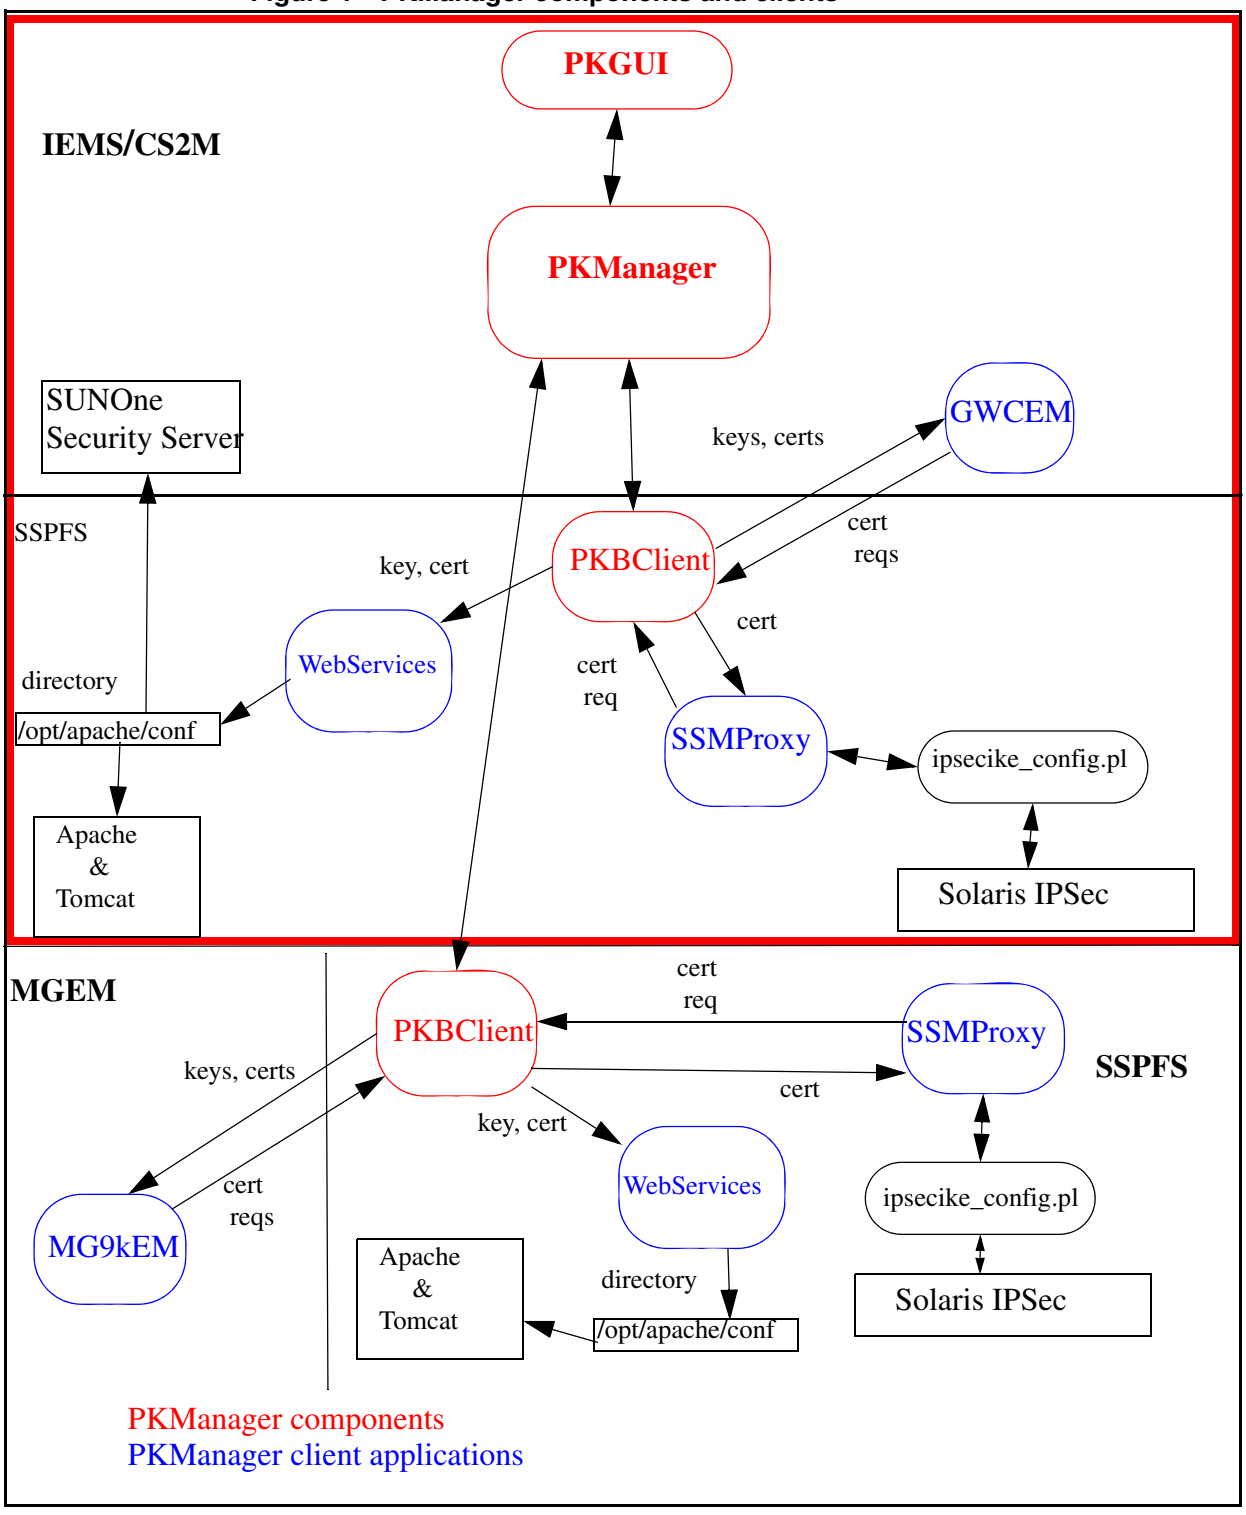
130.2.1 PKManager

The PKManager provides the user with the ability to automate the tracking and management of certificate replacement for the following supported devices:

- MG9KEM
- MG9K
- GWCEM
- GWC
- SSM
- WebServices

The following figure shows the PKManager relationships with its client components.

Figure 1 PKManager components and clients



Note: Certificates are always delivered directly to the active unit of an HA cluster and then mirrored using filesystem synchronization services.

The PKManager automates the management and replacement of device certificates for supported devices. In addition to this, a Web interface (PKGUI) is available to authorized users to perform a variety of manual actions. This GUI can be launched independently from a web browser or from within the IEMS client window. A new application managed object is added to IEMS to allow single sign-on launching and alarm integration for the PKManager with IEMS.

Note: This tool restricts access to users belonging to the authorization groups "***secadm***" and "***secro***". All operations in the GUI will check for group membership before allowing access to a given operation. The group "***secadm***" is used to permit all operations in this tool; while "***secro***" is used to permit viewing and browsing only. See CN doc for this feature for further operation mapping details.

The section following summarizes the operations available to the user through the PKGUI interface. **Further details on the PKGUI can be found in the configuration document for this feature**.

130.2.2 PKGUI User Operations

1 **Generate CSR for Export** - this request is used to initiate the process of importing certificates that are generated by a commercial or external certificate authority. This request will cause the PKBroker to generate a file that contains an openssl PKCS#10 certificate signing request.

2 **Import Certificate for Integrated Client** - this request is used to import a certificate generated by a commercial or external certificate authority. By doing so the certificate management and monitoring services of the PKManager for a device whose certificate management is integrated with that supported by the PKManager are obtained. The matching CSR must be present to successfully import the associated certificate.

3 **Import Certificate for Non-Integrated Client** - this request is used to obtain the expiration monitoring services of PKManager for a certificate that authenticates a device whose certificate management is not integrated with that supported by the PKManager.

4 **Create Non-Integrated Certificate for Export** - this request is used to have the PKBroker generate a file that contains a private key, a second file that contains a compatible X509 v3 certificate for a non-integrated device whose certificate management is not integrated with that supported by the PKManager. PKBCA signing and root certificate files are also provided

for export. The expiration monitoring services of PKManager are activated on the certificate.

5 **Create Integrated Certificate for Export** - this request is used to have the PKBroker generate a file that contains a private key, a second file that contains a compatible X509 v3 certificate for a device whose certificate management is integrated with that supported by the PKManager. PKBCA signing and root certificate files are also provided for export. The expiration monitoring services of PKManager are activated on the certificate. Integrated applications that require manual installation of initial certificates are handled through this request.

6 **Revoke Certificate** - this request is used to immediately revoke any certificate that is monitored by the PKManager. Integrated device certificates that are revoked result in creation and delivery of replacement certificates using the appropriate process (notify of replacement or notify request CSR).

7 **Revoke CA Certificate** - this request is used to initiate the CA certificate replacement procedures for a certificates generated by the PKManager. This is potentially a highly processing intensive procedure that can take several hours to complete depending on the device types and number of certificates that must be replaced.

8 **Inherit Certificate** - this request is used to import a WebServices certificate generated by a commercial or external certificate authority. By doing so the certificate management and monitoring services of the PKManager are obtained. This enables a purchased and the valid certificate to continue to be used.

9 **Browse certificates** - The PKGUI provides the user with the ability to list managed certificates and their states.

10 **Alarm Browser** - PKGUI provides access to view all outstanding alarms generated by the PKManager. PKManager logs and alarms can be found in the fault management section of this feature.

See the Configuration section of this feature for further user interface details.

130.2.2.1 MG9K-EM

MG9kEM is enhanced to support the use of public key certificates for securing the MG9k's OAM&P link and the VMG call control links. MG9kEM will be used to provision, distribute and manage the public key certificates for the MG9k gateways.

See the Configuration section of this feature for further user interface details.

130.2.2.2 GWC-EM

The intent of this development is to address the need to support large scale IP telephony deployments which require digital certificates for authentication.

Digital certificates are used mainly to support IPSEC which is used by NE's (for example GWCs, MG9000) to insure secure call control message communications. They are also used on a smaller scale for secure communication between element managers and network elements.

The GWCEM will retrieve the certificates and private key from IEMS and provision, distribute and manage them for the GWCs.

The GWCEM GUI is changed to allow customer to enable IKE authentication in communication between Gateway Controller and Media Gateway.

- Create/Change IKE authentication item.
- Apply IKE authentication to Connection Policy.
- View/Replace PKI certificate chain.

See the Configuration section of this feature for further user interface details.

130.3 Hardware Requirements or Dependencies

There are no hardware dependencies imposed by this feature.

130.4 Software Requirements or Dependencies

PKManager

The PKManager will initially be bundled and installed as part of IEMS installation on SSPFS. The application itself depends on certain common functions provided by SSPFS to provide consistency with other solution components. These include logging, security, and database services.

MG9KEM

The Mg9kEM PKI support is dependent on the PKBroker software running on SN09.x IEMS and PKBClient software running on SN09.x SSPFS.

The new Mg9kEM PKI capabilities are only supported for Mg9k gateways running SN09.x and newer software loads.

GWCEM

N/A

130.5 Limitations and restrictions

PKManager

MG9KEM

GWCEM

In order to provide backwards compatibility, for pre-SN09.1 GWC loads, only one authentication method can be selected. see CN doc

130.6 Interactions

PKManager

The PKManager interacts with its clients through the PKBClient interface introduced into all SSPFS installations. Each supported client application communicates with the PKManger through this interface.

MG9KEM

The IPsec and IKE provisioning is controlled at the SSM and not the Mg9kEM. Adding/deleting policies may result in communication loss between the EM and Mg9k.

Enabling security for the Mg9k is done from the LCI; not from the EM.

Mg9kEM PKI support does not change the existing IPSec preshared key procedures.

GWCEM

N/A

131: Functional Description (FN) A00012198

131.1 Feature name and Feature ID

A00012198 - GLC12 Coin Card Support from EM

131.2 Description

This GLC12 card is replacing the existing SAA12 card. So this card has to support all the capabilites of the SAA card inclusive of the coin telephone support.

This feature is supported in SN09.1 release. When the user opens the GLC12 card view, the GLC12 card details will be displayed and with twelve port graphics for the GLCports (The GLC12 card has twelve ports). When the user double clicks on the port icon, the GLC circuit view will be displayed. The GLC12 circuit view will display circuit details.

The user will be able to replace the SAA12 with GLC12 without deprovisioning the card. When the card is replaced, the EM will update its details.

131.3 Hardware Requirements or Dependencies

GLC12 card with 12 ports is required.

131.4 Software Requirements or Dependencies

The MG9000 with GLC12 card and support load is required.

131.5 Limitations and restrictions

Since this new GLC12card is patched back in GW till SN08, but not on EM, this card would be displayed as SAA12 in SN08 and SN09 EM.

131.6 Interactions

NONE

131.7 Glossary

SAA12: Service Adaptive Access Line Card w/12 circuits, Supports POTS, GND, Pphone, Coin

GLC12: Global Line Card w/12 circuits Supports POTS, GND, Pphone, Coin.

MG9000: Media Gateway 9000

MG9KEM: MG9K Element Management System

132: Functional Description (FN) A00012199

132.1 Feature name and Feature ID

A00012199 - MG9K EM CPR Robustness

132.2 Description

This feature is supported for MG9Ks with version SN091 and greater. This feature will be supported for all the types of NEs present in subnet (e.g. discovered and undiscovered). The following will be supported for this feature.

1 The craftsperson will be able to initiate an LCI session directly from the MG9K EM subnet screen for all the nodes. It is mandatory that browser path is defined in OS environment. LCI will be invoked on Netscape browser for Unix OS and default browser on a Windows PC. As EM GUI can be launched only from Solaris and Windows PC, this behavior is supported only in Solaris and Windows OS.

The craftsperson must be warned that modification made at LCI may result in node isolation and hence will be required to type (not click) “Agrees” before launching browser.

The craftperson will be given an option of connecting to LCI through inband or out of band.

2. The craftsperson will be able to launch a "clear persist and discover" operation from the MG9K EM for all the nodes.

The craftsperson will be warned that the “clear persist and discover” operation will disrupt services, and will result in an outage condition, and will be required to type (not click) “Agrees” prior to action being taken.

132.3 Hardware Requirements or Dependencies

There is no specific hardware required for this feature.

132.4 Software Requirements or Dependencies

This feature needs changes on the MG9K also and depends on the same.

132.5 Limitations and restrictions

1 The MG9K EM client should have browser path defined on the OS environment. For Unix OS “PATH” environment must have Netscape path defined. For Window OS, the default browser must be set to either Netscape or Internet Explorer.

2 If the browser is already open, LCI session will be launched on the same browser window.

3 When craft person selects the option of launching LCI through inband IP of MG9K, he/she must be aware that if inband address of MG9K is allocated from a private co-lan address space, a client located on the same co-lan or a client which had been connected to the co-lan via a VPN firewall will be able to launch the LCI session. Hence the networking routing is very important while launching the LCI through inband IP. Valid network routing can be checked using ping & traceroute commands. Either command line or “Configuration -> Tools” subnet EM menu can be used for these utilities.

4 LCI out of band access is only available if face plate ethernet is connected on the supercore and a valid out of band IP has been previously configured at LCI.

5 If the LCI browser session returns 404 not found, use the ping command to verify that the out of band address on MG9K responses. The out of band address is the address in the URL shown on the browser screen when out of band LCI is launched.

6 If ping and traceroute do not succeed, the swact of SCO on MG9K may restore connectivity.

132.6 Interactions

134: Functional Description (FN) A00012210

134.1 Feature name and Feature ID

A00012210: Geo OA&M Automatic Backup and Accelerated Restore

134.2 Description

This Automatic Backup and Accelerated restore feature, henceforth referred to as "remote backup", will remotely backup all data on the “target” unit. This provides a standby backup system ready to provide service should the primary system or cluster be unavailable for an extended period of time (e.g., catastrophic site loss). The remote backup can assume the identity of the target system with data and files accurate to the last sync. This feature is driven by the geographic survivability configuration where the remote backup will be at a different site from the target system. Previous backup relied on physical media which needs to be transported between the primary and backup systems. Also, the media based restore requires a multistep restore process.

This feature performs the backup via TCP/IP connection and stores an exact copy on the standby server which can be quickly and remotely activated. The data is transferred via an encrypted ssh tunnel over the CS LAN. This remote backup copies all files in each file system marked for backup. This is the same behavior as a full system backup.

If the file system layout has not changed, the backup will transfer file differences since the last backup, a practice commonly referred to as an incremental backup. This is a built in feature of the open source rsync tool. By transferring only differences there are major savings in time and bandwidth.

A remote backup configuration tool is provided to set the necessary parameters and schedule for automatic backup. These backups can be scheduled to automatically occur from once a day to four times per day. Users will be able to enter up to four times of their choice for the automatic backup to occur. For example, "02:00", "06:00", "15:00" and "21:00". This tool also provides a facility for manually initiating a backup and monitoring its progress. Each remote backup session will provide detailed logs of that session.

The standby server has an identical copy of files from the last backup, so it can become the primary system via changing the boot pointer and rebooting. When it boots it will have the IP address and all configuration as of the last backup.

When the primary site is again available, the remote backup feature can be reused to transfer current system configuration back to the primary site and system.

Following is a high level overview for OA&M recovery using the standby server:

1. Normal state: primary site is providing service and the standby site is automatically backing up data at the scheduled times.
2. Primary site goes down. Craft person can remotely login to the standby system and activate the standby backup system.
3. The standby system boots with the configuration and data from the primary site as of the last scheduled backup. Standby site provides service.
4. Sometime later the primary site is repaired. To transfer "current" data and setting from the standby to the primary site, a craft person at the primary site installs cluster unit0 as a remote backup system.
5. Craft person at the primary site performs a remote backup of the standby site.
6. Standby site can be remotely shutdown and primary site activated
7. Primary site should clone the other cluster unit to restore normal cluster operations.
8. Craft person at standby site will need to install the standby system for automatically backing up data. Once this is complete, everything is back to the normal state.

134.3 Hardware Requirements or Dependencies

The hardware of the standby server must match the primary server. This is especially important with regard to hard disk size. This feature is supported with Sun Netra 240 servers.

134.4 Software Requirements or Dependencies

(I)SN09 or higher release.

134.5 Limitations and restrictions

Scheduled backups to the standby server will not complete if a full system backup of the primary HA server pair is in progress.

134.6 Interactions

This feature is very similar to a full system backup. The interactions are similar to the existing full system backup. Due to the exclusive use of file system snap shots, a full system backup to local media and a remote backup to a standby system can not be running at the same time. If the remote backup function detects either of these in progress, it will cleanly exit and re-try at the

next scheduled backup. If a local full system backup is attempted while a remote backup is in progress it will indicate that another backup is in progress and will exit.

Remote system backup should not have any interactions with SBA file transfer via ftp or SBA backup to DVD.

134.7 Glossary

Term	Description
New term	Definition

135: Functional Description (FN) A00012215

135.1 Feature name and Feature ID

A00012215 - Global Line Card Field Programmable Gate Array

135.2 Description

Currently, GLC cards do not have any loads which need to be downloaded from the MG9k Element Manager. The FPGA is currently flashed directly onto the board. In SN09.1, new GLC hardware is introduced which has the capability for the FPGA to be downloaded. The GLC cards must provide the capability for software download of the FPGA. This capability prevents any class “A” retrofits of the GLC-32 or GLC-12 due to a configuration load issue in the FPGA on the card. The NY53BA card replaces the existing POTS-32 and GLC-32 cards.

This feature also covers the need to be able to reload a single circuit controller on the GLC card from the EM. Currently, when the line card is force locked all 8 of the circuit controllers on the GLC-32 cards are reloaded. Each circuit controller controls 4 line circuits. The reload is taking upwards of 4 minutes for a single card which is too long to reload a card. Therefore, we need to be able to reload a single circuit controller on the GLC instead of all 8 being reloaded at the same time.

135.3 Hardware Requirements or Dependencies

Hardware produces the GLC loads for the FPGA configuration load. It is assumed different GLC loads are produced for each different GLC PEC code. The MG9kEM depends upon hardware to produce the different GLC loads for each GLC PEC code.

The GLC can be plugged into any version of the gateway but until the ITP card is running a load that is able to download the GLC FGPAs, the download will not work since the ITP is used to perform the software download to the GLC FPGA. The ITP provides a temporary location to store the FPGA load until it is moved to the GLC card.

Hardware must provide a mechanism to read the FPGA load name in order to display the loadname to the customer. The load name would allow the customer to figure out if the FPGA for the particular vintage of GLC needed to be software downloaded with a new load.

Hardware also produces the coefficients for each GLC PEC code. This new GLC card depends upon hardware to produce a copy of coefficients for this new GLC PEC code.

135.4 Software Requirements or Dependencies

The new GLC download file is loaded onto the SDM/CBM along with the other gateway loads. The MG9kEM software must be at SN09.1 or patched with this feature content in order to provide the software download capability to the GLC card.

Replacing GLC FPGA loads is a function of the gateway loadbuild process. The MG9kEM assumes there is a process in place for replacing GLC loads at the customer site in the event a new GLC load is required outside the normal software release cycle.

135.5 Limitations and restrictions

GLC NTNY53AA and NTNY53AB cards can not be software downloaded.

The GLC downloading capability is available once the GLC card PEC code is NTNY53BA or greater.

Software downloading FPGAs on GLC cards require the GLC card to be locked and thus affects call processing.

The GLC cards are not downloaded as part of a release to release upgrade. The GLC cards can be downloaded after the entire network element, MG9k, has been upgraded if required. Or can be downloaded prior to a release to release upgrade if absolutely required. The preferred method of downloading is to download once the entire network element has already been upgraded.

Running diagnostics on the circuit controller affects 4 circuits at the same time. If the circuit controller needs to be restarted, call processing is affected.

No alarms are output in the event two GLC cards with the same PEC code have different configuration loads.

Unlike the MTA Card View where the customer sees two downloadable loads which can be used to restart the card. The GLC card view only shows a single FPGA configuration load. There is no backup load for the GLC FPGA. There is no restart load capabilities on the GLC card.

135.6 Interactions

Software upgrades - From the frame view, all of the GLC cards for a particular vintage can be downloaded. The GLC software download does not apply to every release to release upgrade. Hopefully, only in rare instances would a new GLC FPGA load be release. Therefore, the upgrade CLUI does not include GLC as a downloadable component. GLC cards must be locked prior to attempting a software download.

Diagnostics- If the circuit controller needs reloading during a circuit controller diagnostic test, 4 circuits are affected. Call processing is dropped during a circuit controller reload. If the circuit controller does not need reloading during the diagnostic, as determined by the gateway, no reload occurs and calls remain operational.

There are no patching interactions since the GLC card can not be patched. The GLC card can not be imaged as well.

135.7 Glossary

136: Functional Description (FN) A00012223, A00012217, A00012225

136.1 Feature name and Feature ID

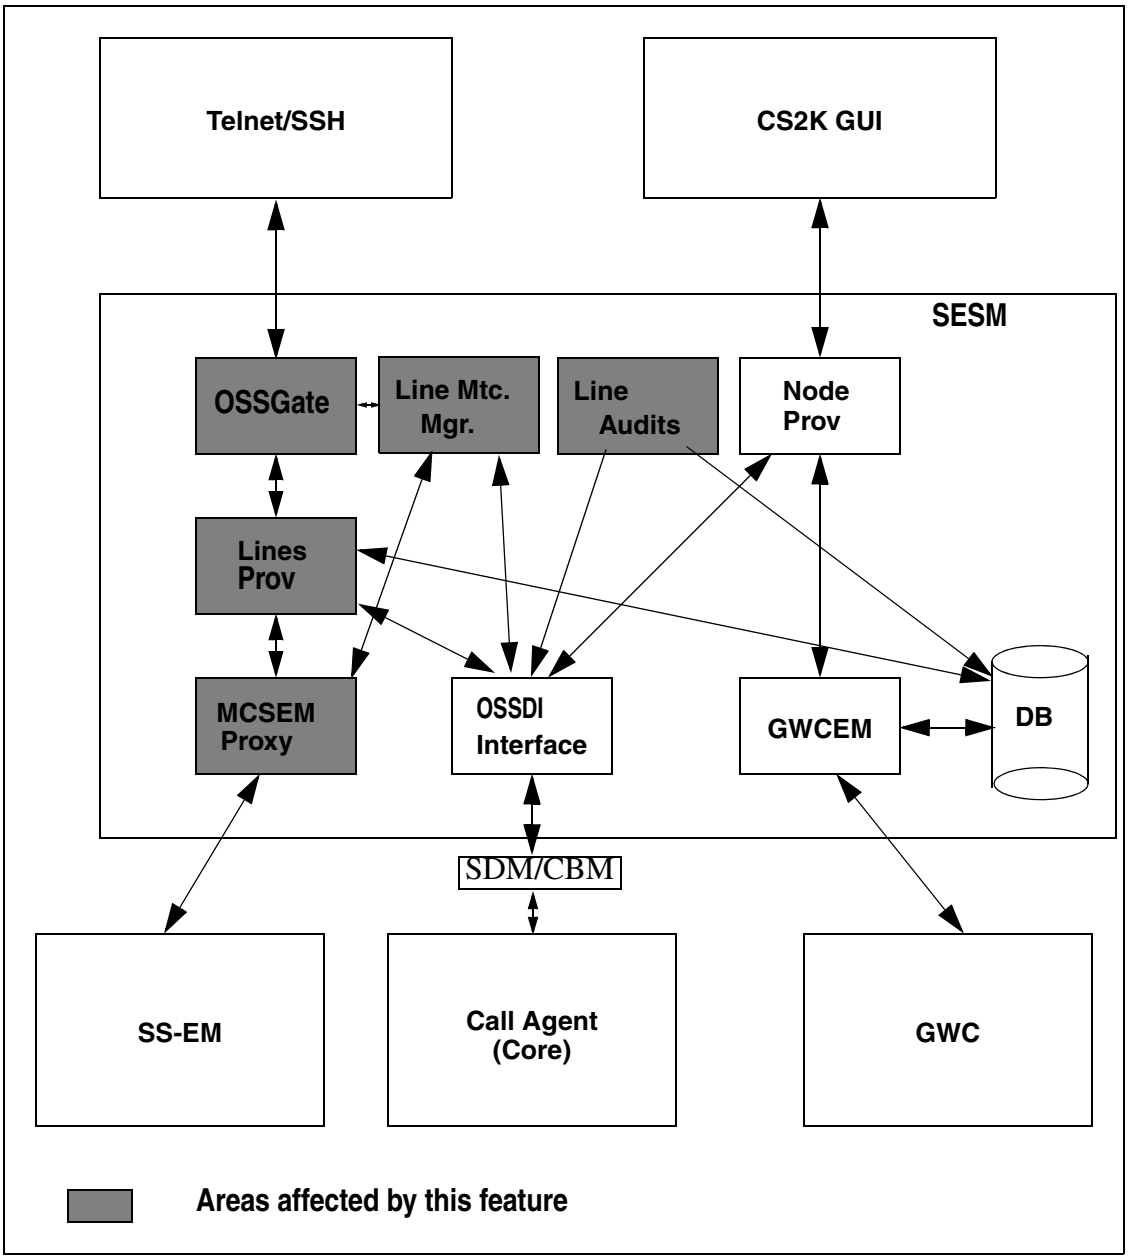
A00012223, A00012217, A00012225--SESM Support for SIP Lines, Part 2

136.2 Description

This activity, SESM Support for SIP Lines Part 2, consists of 3 features:

- A00012223 - SESM: SESM: Additional Provisioning for SIP Lines
  A richer set of SERVORD+ and query commands will be supported for SIP lines. Some of the newly supported commands and will trigger flowthrough of new data to the Session Server Element Manager (SS-EM). The support of HUNT and MADN commands will entail new flowthrough logic for group information to the SS-EM.
- A00012217 - SESM: SIP Lines - Data Sync Audit
  The Line Audit feature component will add auditing coverage of SIP line data on the SS-EM. The data to be audited on the SS-EM includes the Directory Number(DN), the termination name, the Virtual Media Gateway (VMG), and the HUNT/MADN group name information.
- A00012225 - SESM: SIP Lines - Maintenance Enhancements
  Maintenance Enhancements introduces a Services Maintenance Command Line User Interface (CLUI) to replace the LMM GUI and eventually the LTP (Lines Test Position) level of the MAPCI.
  For the introduction, this CLUI will allow the user to post Succession and non-Succession lines (TDM) and perform functions similar to that of the LTP level. This LMM CLUI defined in this document will be generic, intended for use with line or gateway types other than SIP.

Figure 1 Functional Behavior Diagram



136.2.1 Line Maintenance Manager CLUI

The LMM CLUI performs similar functions as the LMM GUI, providing a human/machine interface to view LMM configurations, generate “Query GW in Trouble” reports and line maintenance commands.

136.2.2 Configure

In the SESM, the /opt/nortel/NTsesm/admin/bin/configure tool must be used to configure SESM access to the Session Server Element Manager (SS-EM). This tool is currently used to provision the OPI link. The OMI link requires similar entries.

```
SESM-CS2KSS configuration

OPI - Provisioning Manager Interface configuration

Enter OPI transport protocol to EM server ( http/https - default: https)
 [1] - http
 [2] - https
 [x] - exit

select - 2

 Enter the IP address / Name of the primary CS2KSS prov server (default:
47.142.91.164) : 47.142.91.164
 Enter the primary CS2KSS prov server https port (default is 8443): 8443

 Enter the IP address / Name of the secondary  CS2KSS prov server (default:
47.142.91.164) : 47.142.91.164
 Enter the secondary CS2KSS EM server https port (default is 8443): 8443

 Enter the OPI administrator user name (default: admin): admin

 Enter the OPI administrator password:
 Re-enter the OPI administrator password:

OMI - Provisioning Manager Interface configuration

Enter OMI transport protocol to EM server ( http/https - default: https)
 [1] - http
 [2] - https
 [x] - exit

select - 2

 Enter the IP address / Name of the primary CS2KSS mtc server (default:
47.142.91.164) : 47.142.91.164
 Enter the primary CS2KSS mtc server https port (default is 12121): 12121

 Enter the IP address / Name of the secondary  CS2KSS mtc server (default:
47.142.91.164) : 47.142.91.164
 Enter the secondary CS2KSS mtc server https port (default is 12121): 12121

 Enter the OMI administrator user name (default: admin): admin

 Enter the OMI administrator password:
 Re-enter the OMI administrator password:

OPI - Provisioning Manager configuration
```

```
Transport protocol to EM server                   :   https://
Primary CS2KSS Provisioning Manager IP / Name     :   47.142.91.164
Primary CS2KSS Provisioning Manager port          :   8443
Secondary CS2KSS Provisioning Manager IP / Name   :   47.142.91.164
Secondary CS2KSS Provisioning Manager port        :   8443
The administrator user name                       :   admin

OMI - Maintenance Manager configuration

Transport protocol to Maintenance Manager         :   https://
Primary CS2KSS Maintenance Manager IP / Name      :   47.142.91.164
Primary CS2KSS Maintenance Manager port           :   12121
Secondary CS2KSS Maintenance Manager IP / Name    :   47.142.91.164
Secondary CS2KSS Maintenance Manager port         :   12121
The administrator user name                       :   admin

Is the information correct? (y or n) :
```

The configuration tool will prompt the user to enter the following for the OMI link information:

- Transport protocol to SS-EM server (https).
- IP address / host name of primary SS-EM server
- IP address / host name of secondary SS-EM server. Some configurations may not include a secondary SS EM server. If so, configure the same information provided for the primary server (by default this should be the case).
- HTTPS communication port to SS EM server (12121).
- SS-EM Provisioning Manager administrator user name
- SS-EM Provisioning Manager administrator password

The OPI version information is not required anymore since it is dynamically determined when the OPI and OMI links come into service.

The IP address and port will be used to generate the SS-EM Provisioning Manager URL which in turn will be added to sesm.properties file.

As part of the configuration, the IP address will be validated for format, range and reachability. Other user entered data will be validated for format, range, values etc.

The user name will be added to sesm.properties as clear text.

The password will be stored separately and accessible only to the root user.

All configuration information (url, username, etc.) except password can be displayed by using the SESM “/opt/nortel/NTsesm/admin/bin/configure” tool.

136.2.3 Audits

The Line Audit will now audit the endpoints of Session Server EM with GWCEM and compare group information in SS EM with core and also compare DN to LEN mapping stored in SS EM with core. See section “2.6.2 Line Audit” for information on changes to GUI, BPT, and audit output data (valid and problem log file)

136.2.4 Line Provisioning

Existing support for provisioning SIP lines at OSSGate via SERVORD+ commands will be extended to include a more robust and richer set of commands. See section “136.6.2 SERVORD+ via OSSGate” on page 1304 for detailed information.

136.3 Hardware Requirements or Dependencies

Not applicable.

136.4 Software Requirements or Dependencies

This actrivity requires that the following components are loaded with SN09 drop 2 or equalivalent loads.

CM, XAC or 3PC

GWC

MSM

136.5 Limitations and restrictions

136.5.1 SERVORD+ via OSSGate

See “136.6.2 SERVORD+ via OSSGate” on page 1304 for the various limitations and restrictions related to the support for the expanded set of SERVORD+ commands.

136.6 Interactions

136.6.1 LMM CLUI

To access the LMM CLUI telnet to OSSGate, enter ^B, “mode MTC”. Once in the MTC level, “LMM” is entered for access to the LMM CLUI.

```
>
? mode MTC

Mode is MTC.
```

The CMCLLI command is used to return the SDM IP and CMCLLI name:

```
>CMCLLI
      SDM IP = 47.142.134.124
      CM CLLI = RTP2
```

```
>LMM
      report <-v>
      report <-l> <report name>
      report <-gen> <GWC Options>

      post <-d, -l, -gw, -u, -r, -set, -display, -count>

      bsy <-d, -l, -gw, -set> [inb]
      rts <-d, -l, -gw, -set>
      tst <-d, -l, -gw, -u, -set>
      FRLS <-d, -l>

      qdn <dn>
      qlen <len>
      qsip <dn, len>

      help

      quit
```

The commands (i.e. report, bsy) can be entered in either upper or lower case. The options (i.e. -d, -l) must be entered in lower case. The parms can be entgered in either case but in the case of the GW name, should be in the proper case.

136.6.1.1 REPORT Commands

The REPORT commands are used with the GW in Trouble reports. Using the commands, the user has the ability to list, view and delete any of the reports. The GENERATE or GEN is used to run the process to create a report.

Command format:

```
report <-l>
report <-v> <REPORT NAME>
report <-gen> <GWC List | all>
```

Command usage:

To obtain a list of reports currently available

```
>report -l
The following reports are available:
Report-2005-08-10-22-06-14
```

To view a specific report

```
>report -v Report-2005-08-10-22-06-14
GW Name   Results for GWC-0
t1124ent.us.nortel.com   GW DISABLED

GW Name   Results for GWC-10
test4   GW DISABLED
```

To request a new GW in Trouble report for GWC 1

```
report -gen 1
```

To request a new GW in Trouble report for GWC 1, 2 and 3

```
report -gen 1, 2, 3
```

or

```
report -gen 1-3
```

or

```
report -gen 1, 2-3
```

To request a new GW in Trouble report for all valid (small and large line) GWCs

```
report -gen all
```

136.6.1.2 MTC Commands

This set of commands is used to perform operations on either one or a set of lines.

Command format:

```
post -d <DN> [verbose]
post -l <LEN> [verbose]
post -gw <GW/VMG> [verbose]
post -u <URI> [verbose]
post -r <Domain name> [verbose]
post -display [verbose]
post -count

bsy -d <DN> [inb]
bsy -l <LEN> [inb]
bsy -gw <GW or VMG> [inb]
bsy -set [inb]

rts -d <DN>
rts -l <LEN>
rts -gw <GW/VMG>
rts -set

tst -d <DN>
tst -l <LEN>
tst -gw <GW/VMG Name>
tst -u <URI>
tst -set

frls -d <DN>
frls -l <LEN>
```

136.6.1.2.1 REPORT Commands

The REPORT commands are used with the GW in Trouble reports. Using the commands, the user has the ability to list and view any of the reports. The -gen is used to run the process to create a report.

Command format:

```
report <-l>
report <-v> <REPORT NAME>
report <-gen> <GWC List | all>
```

Command usage:

To obtain a list of reports currently available

```
>report -l
The following reports are available:
Report-2005-11-14-12-12-01
```

To view a specific report

```
>report -v Report-2005-11-14-12-12-01
GWC-14  Number of GWs out of service = 1

R7A20204.rtp7.net status = GW DISABLED

GWC-13  Number of GWs out of service = 11

To request a new GW in Trouble report for GWC 1
report -gen 1
```

To request a new GW in Trouble report for GWC 1, 2, 3 and 4

```
report -gen 1, 2, 3, 4
```

or

```
report -gen 1-4
```

or

```
report -gen 1, 2-4
```

To request a new GW in Trouble report for all valid (small and large line) GWCs

```
report -gen all
```

136.6.1.2.2 POST

The POST command can be used to generate a set of lines and be used for maintenance (BSY, etc.) actions.

The POST command will list the contents of the post set to the screen using a “brief” format. The information listed will be dn, len, uri, clientIp, gwc, lcc, cm line state, scc line state and MCS line state (if a SIP Line).

The VERBOSE option includes included the above and adds the following, GW/VMG name, GW ipaddress, GW type, endpointName, domain/ subdomain.

To post by DN (SIP Line)

```
      >post -d 7550505
DN         = 6137550505
LEN        = SS 00 0 00 05
LCC        = IBN
GWC NAME   = GWC-5
GW NAME    = rtp7ssa
EPT NAME   = SS/000/0/0005
GW EPT ST  = ON-HOOK
CM EPT ST  = IDL
SIP URI    = user5@rtp7ssa.com
CLIENT IP =
SS EPT ST =
```

```
Number of endpoints returned = 1
```

To post by DN, non SIP Line

> post -d 6210010

```
DN         = 6136210010
LEN        = UAIP 00 1 00 00
LCC        = IBN
GWC NAME   = GWC-14
GW NAME    = rtp7-1104b.us.nortel.com
EPT NAME   = aaln/1
GW EPT ST  = ON-HOOK
CM EPT ST  = IDL

Number of endpoints returned = 1
```

To post by LEN:

```
      > post -l ss 0 0 0 5
DN         = 6137550505
LEN        = SS 00 0 00 05
LCC        = IBN
GWC NAME   = GWC-5
GW NAME    = rtp7ssa
EPT NAME   = SS/000/0/0005
GW EPT ST  = ON-HOOK
CM EPT ST  = INB
SIP URI    = user5@rtp7ssa.com
CLIENT IP =
SS EPT ST =
```

To post by GW:

Note: Since the minimum VMG sizze for SIP is 1023 endpoints, posting by vmg may take a long time (approx 5 mins per LGRP) and will produce a huge output.

```
      > post -gw rtp7-1104b.us.nortel.com
DN         = 6136210010
LEN        = UAIP 00 1 00 00
LCC        = IBN
GWC NAME   = GWC-14
GW NAME    = rtp7-1104b.us.nortel.com
EPT NAME   = aaln/1
GW EPT ST  = ON-HOOK
CM EPT ST  =

DN         = 6136210011
LEN        = UAIP 00 1 00 01
LCC        = IBN
```

```
GWC NAME  = GWC-14
GW NAME   = rtp7-1104b.us.nortel.com
EPT NAME  = aaln/2
GW EPT ST = ON-HOOK
CM EPT ST =

DN        = 6136210012
LEN       = UAIP 00 1 00 02
LCC       = RES
GWC NAME  = GWC-14
GW NAME   = rtp7-1104b.us.nortel.com
EPT NAME  = aaln/3
GW EPT ST = ON-HOOK
CM EPT ST =

DN        = 6136210013
LEN       = UAIP 00 1 00 03
LCC       = RES
GWC NAME  = GWC-14
GW NAME   = rtp7-1104b.us.nortel.com
EPT NAME  = aaln/4
GW EPT ST = ON-HOOK
CM EPT ST =
```

To post by URI:

```
      > post -u user5@rtp7ssa.com
DN        = 6137550505
LEN       = SS 00 0 00 05
LCC       = IBN
GWC NAME  = GWC-5
GW NAME   = rtp7ssa
EPT NAME  = SS/000/0/0005
GW EPT ST = ON-HOOK
CM EPT ST =
SIP URI   = user5@rtp7ssa.com
CLIENT IP =
SS EPT ST =
```

To post Registered users by domain. This command will return the users that have registered their clients with their provisioned domains.

Note: This command may take a long time and will produce a huge output.

```
      > post -r rtp7ssa.com
DN        = 6137550505
LEN       = SS 00 0 00 05
LCC       = IBN
GWC NAME  = GWC-5
GW NAME   = rtp7ssa
EPT NAME  = SS/000/0/0005
GW EPT ST =
CM EPT ST =
SIP URI   = user5@rtp7ssa.com
CLIENT IP =
SS EPT ST =

DN        = 6137550510
LEN       = SS 00 0 00 10
LCC       = IBN
GWC NAME  = GWC-5
GW NAME   = rtp7ssa
```

```
EPT NAME  = SS/000/0/0010
GW EPT ST =
CM EPT ST =
SIP URI   = user10@rtp7ssa.com
CLIENT IP =
SS EPT ST =

Number of endpoints returned = 2
```

To display the contents of the post se using the verbose option:

```
      >  post -display verbose
DN         = 6137550505
LEN        = SS 00 0 00 05
LCC        = IBN
GWC NAME   = GWC-5
GW NAME    = rtp7ssa
EPT NAME   = SS/000/0/0005
GW EPT ST  = ON-HOOK
CM EPT ST  = IDL
SIP URI    = user5@rtp7ssa.com
CLIENT IP  =
SS EPT ST  =
Node Num   = 213
Term Num   = 6
GWC IP     = 47.142.92.172
GW IP      = 47.142.91.154
GW TYPE    =
```

To display the number of entries in the post set:

```
      >post -count
      Post set size = 104
```

136.6.1.2.3 BSY

The BSY commands informs the CM to perform the requested action. A response message indicates the success or failure of the command. These messages are generated by the CM.

To Maintenance/Manual Busy a line by DN:

```
      > bsy -d 7550505
DN = 7550505
CM RETURN CODE = CM_OK
```

To Maintenance/Manual Busy a line by LEN:

```
      >  bsy -l ss 0 0 0 5
LEN = ss 0 0 0 5
CM RETURN CODE = CM_OK
```

To Maintenance/Manual Busy all lines on a GW:

```
      > bsy -gw rtp7-1104b.us.nortel.com
DN = 6136210010
CM RETURN CODE = CM_OK
DN = 6136210011
CM RETURN CODE = CM_OK
DN = 6136210012
```

```
CM RETURN CODE = CM_OK
DN = 6136210013
CM RETURN CODE = CM_OK
```

To Busy by the posted set:

```
      > bsy -set
DN = 6136210010
CM RETURN CODE = CM_OK
DN = 6136210011
CM RETURN CODE = CM_OK
DN = 6136210012
CM RETURN CODE = CM_OK
DN = 6136210013
CM RETURN CODE = CM_OK
```

The BSY INB operation performs two operations; first is a BSY then upon success, performs the INB operation. If the line is already in the BSY state then only the INB operation is performed.

If the line is IDL

```
      >  bsy -d 7550505 inb
DN = 7550505
CM RETURN CODE = CM_OK
DN = 7550505
CM RETURN CODE = CM_OK
```

If the line is BSY

```
> bsy -d 7550505 inb
DN = 7550505
CM RETURN CODE = CM_ALRDY_IN_REQ_STATE
DN = 7550505
CM RETURN CODE = CM_OK
```

136.6.1.2.4 RTS

To return-to-service a line by DN:

```
      > rts -d 7550505
DN =  7550505
CM RETURN CODE = CM_OK
```

To return-to-service a line by LEN:

```
      >  rts -l ss 0 0 0 5
LEN = ss 0 0 0 5
CM RETURN CODE = CM_OK
```

To return-to-service all lines on a GW:

```
      > rts -gw rtp7-1104b.us.nortel.com
DN = 6136210010
CM RETURN CODE = CM_OK
DN = 6136210011
CM RETURN CODE = CM_OK
DN = 6136210012
```

```
CM RETURN CODE = CM_OK
DN = 6136210013
CM RETURN CODE = CM_OK
```

To Busy by the posted set:

```
      > rts -set
DN = 6136210010
CM RETURN CODE = CM_OK
DN = 6136210011
CM RETURN CODE = CM_OK
DN = 6136210012
CM RETURN CODE = CM_OK
DN = 6136210013
CM RETURN CODE = CM_OK
```

136.6.1.2.5 TST

The TST performs a diag (where possible) depending upon the GW's ability to perform diagnostics on endpoints. Only GCP and MGCP GWs support the TST command.

To test by DN (SIP):

```
> tst -d 7550505

DN = 6137550505
LINE_STATE = PASSED
ENDPOINT_STATE = UNKNOWN
CLIENT = user5@47.142.166.65
TEST RESULT = PASSED
```

To test by DN (MGCP line):

```
> tst -d 6210010

DN = 6136210010
LINE_STATE = ON-HOOK
ENDPOINT_STATE = OK
```

To test using the LEN (SIP)

```
      > tst -l ss 0 0 0 5

DN = 6137550505
LINE_STATE = PASSED
ENDPOINT_STATE = UNKNOWN
CLIENT = user5@47.142.166.65
TEST RESULT = PASSED
```

To test using the URI

```
      > tst -u user5@rtp7ssa.com

URI = user5@rtp7ssa.com
LINE_STATE = PASSED
ENDPOINT_STATE = UNKNOWN
CLIENT = user5@47.142.166.65
TEST RESULT = PASSED
```

To test by GW (or VMG).

Note: Testing by VMG may take a long time and produce a large amount of information.

MGCP based GW:

```
> tst -gw rtp7-1104b.us.nortel.com

DN = 6136210010
LINE_STATE = ON-HOOK
ENDPOINT_STATE = OK
DN = 6136210011
LINE_STATE = ON-HOOK
ENDPOINT_STATE = OK
DN = 6136210012
LINE_STATE = ON-HOOK
ENDPOINT_STATE = OK
DN = 6136210013
LINE_STATE = ON-HOOK
ENDPOINT_STATE = OK
```

SIP GW

```
> tst -gw rtp7ssa

DN = 6137550500
LINE_STATE = FAILED
ENDPOINT_STATE = UNKNOWN
ERROR = Test Executed

DN = 6137550501
LINE_STATE = FAILED
ENDPOINT_STATE = UNKNOWN
ERROR = Test Executed
```

136.6.1.3 QUERY Commands

The query commands are used to perform various existing queries. These queries are the same as those from Servord.

Command format:

```
qdn <DN>
qlen <LEN>
qsip <DN, LEN>
```

Command usage:

To Query a DN

```
QDN 7201000
--------------------------------------------------------------------------------
DN:     7201000
TYPE: SINGLE PARTY LINE
SNPA: 619   SIG: DT    LNATTIDX: N/A
LINE EQUIPMENT NUMBER:     SS    00 2 00 00
END POINT: rtp2sesm1  SS/000/2/0000
LINE CLASS CODE:  IBN

136.6.1.4 MISC Commands

To quit from the LMM level - the user will remain in the MTC mode.

```
QUIT
```

136.6.1.5 Command Parsing

Multiple commands can be input input on the same line - they must be separated by a ";". Up to 4 lens, dns or uris can be specified with the POST, BSY, TST and RTS commands. Due to the potential volume of output, only one GW or VMG can be specified.

The commands are not case sensitive, but the parameters may be, ie. GW name will be case sensitive.

136.6.2 SERVORD+ via OSSGate

This feature extend existing capabilities of the Succession SERVORD+ system for SIP client provisioning. SIP client commands/data will distributed to the SS-EM from the SERVORD+ system within the SESM. The following commands will trigger data distribution to the SS-EM from SESM SERVORD+ when SS vmgs/endpoints (or associated LENs) are found within the command:

- NEW
- OUT
- CHF
- ADD
- EST
- DEL
- ADO (for MDN options)

- DEO (for MDN options)
- CDN
- CHF
- CLN/CTP
- QCUST
- QLEN/QTP (show endpoint for HASU SIP LENs)
- QDNWRK (show SIP_DATA queried from SS-EM)
- QLENWRK (show SIP_DATA queried from SS-EM)
- QSIP

For SIP Line clients, the NEW, OUT and CHF commands are currently supported. New development is required to support the remaining commands in this release.

Note: CHF requires the use of gateway/termination names (or the equivalent LEN) in order to trigger data flow through for SS lines. Use of DN instead of primary LEN or gateway/termination will result in the command being processed only by the CM.

Note: CDN commands which modify the DN assigned to the user will ***not*** automatically update the SIP_URI. The use of Directory Number in the SIP_URI value (e.g. 2145209999@nortel.com) is not recommended.

Note: EST/ADD/DEL commands support only single SIP LENs/ Endpoints in the command due to the limitation of a single SIP_DATA option being processed in the options area. Use of multiple SIP LENs/ Endpoints in these commands will result in command failure.

Query commands such as QCUST, QLENWRK and QDNWRK (which return formatted line/service information) will include the SIP_DATA options provisioned via the NEW/EST/ADD/CHF commands in their output. The SIP_DATA option information will be appended to the end of the existing QLENWRK/QDNWRK output, but prior to the dashed line (eg. "----------")query output terminator for each line in the output.

Existing data tags presented in query output with sample values:

END POINT DATA: *(This is the endpoint data header, no info/value associated with this tag)*

SIP_CLIENT_TYPE: sip line

SIP_EP_NAME: SCOT/000/0/0000

SIP_VMG_NAME: vmg1

SIP_DN: 6195209998

SIP_LOCATION: nortel networks.rtp.nc0

SIP_PACKAGE: sip lines

SIP_URI: slynch@mordor.com

New data tags presented in query output with sample values:

SIP_GROUP_DN: 6195209999

SIP_GROUP_TYPE: MLH

SIP_SUBDOMAIN: doom.mordor.com

See query examples in the next section for details on presentation and positioning within query output.

136.6.2.1 SERVORD+ Command Examples

See Configuration Section for SIP_DATA option format details and provisioning rules.

136.6.2.1.1 NEW command Examples:

NEW $ 6195209998 1FR LATA1 0 **SCOT 00 0 00 00** dgt SIP_DATA SIP_PACKAGE SIP Lines SIP_URI slynch@mordor.com SIP_SUBDOMAIN doom.mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0 SIP_PASSWD scott11 $ DPL Y 10 $

NEW $ 6195209998 1FR LATA1 0 **vmg1 SCOT/000/0/0000** dgt SIP_DATA SIP_PACKAGE SIP Lines SIP_URI slynch@mordor.com SIP_SUBDOMAIN doom.mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0 SIP_PASSWD scott11 $ DPL Y 10 $

136.6.2.1.2 CHF Command Examples

The change feature command is currently supported for SIP lines and SIP_DATA except SIP_URI. SIP_URI may be included in the CHF command, but it must match the existing value assigned to the user. Change of the SIP_SUBDOMAIN for the user will be supported.

CHF $ SCOT 00 0 00 00 SIP_DATA SIP_PACKAGE siplines SIP_PASSWD scott11 SIP_CLIENT_TYPE IBN SIP_LOCATION IBM.RTP $ $

CHF $ **vmg1 SCOT/000/0/0000** SIP_DATA SIP_PACKAGE siplines SIP_PASSWD scott11 SIP_CLIENT_TYPE IBN SIP_LOCATION IBM.RTP $ $

Moving a line/user between domains/subdomains can be accomplished using the CHF command. For example, if user slynch@mordor.com is currently provisioned in the root domain (mordor.com) and needs to be moved to subdomain doom.mordor.com, the following CHF command may be used:

CHF $ SCOT 00 0 00 00 SIP_DATA SIP_SUBDOMAIN doom.mordor.com $ $

By simply specifying a SIP_SUBDOMAIN sub-option, the user associated with LEN SCOT 00 0 00 00 will be moved from their currently assigned domain to the value specified by the SIP_SUBDOMAIN sub-option. A user may be moved between root domain and subdomains, between subdomains, or between root domains using this mechanism. However, it is important to note that user moves between domains can have serious consequences on user based data in the Session Server Element Manager. If packages, locations, or group information does not match in the target domain, then the users existing data will be *lost* following the move, replaced by default data in the target domain. **NO WARNING IS GIVEN WHEN THIS OCCURS.** ***Therefore, CHF based user moves should be used with caution as important domain specific data may be lost during the move. QLEN/QDN executed before and after the move should reveal any data mismatch/loss.***

136.6.2.1.3 OUT Command Examples

OUT $ 6195209998 SCOT 00 0 00 00 BLDN

OUT $ 6195209998 **vmg1 SCOT/000/0/0000** BLDN

136.6.2.1.4 QDN and QLEN Query Examples

The following examples of query output show the newly added SIP_DATA sub-options SIP_SUBDOMAIN, SIP_GROUP_TYPE, and SIP_GROUP_DN.

```

136.6.2.1.5 QLEN For HASU LEN

The QLEN command output currently shows endpoint and SIP_DATA information for LENs with assigned service, however no endpoint data is shown for HASU LENs. The output is updated in this release to add the associated endpoint information (if any) to the end of the query output for HASU LENs.

```
>qlen TEST 00 1 01 00

136.6.2.1.6 QCUST

Example command and output for a SIP line:

```
>qcust bnr $
1 SS12 00 6 00 07 IBN PKLNL RDTLSG N
```

```
2 7207167 BNR 0 0 613
9 CWT DGT DPL Y 10 $
23 SIP_URI me@mydomain.com SIP_LOCATION my house
99
```

New record type “23” is introduced which contains SIP_DATA information.

136.6.2.1.7 QDNWRK/QLENWRK

QDNWRK and QLENWRK are bulk queries which display all or ranges of working DNs or LENs. The Detailed output of these commands resembles lists of individual QDN and QLEN query output. A Summary output simply displays a count.

Examples:

```
QDNWRK R 7215554 7215554 NLCC $ D
COMMAND AS ENTERED

136.6.2.1.8 ADO and DEO for MADN

For most forms of ADO/DEO, a SIP line would be unaffected, however adding a MDN option to an existing line may change that line's directory number (set to empty on the Session Server). Adding the MDN option may also trigger group creation on the Session Server if the line is the first Session Server line in the MDN group.

Examples:

```
NEW $ 7215555 IBN BNR 0 0 619 NILLATA 0 C411  01 0 02 00 SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user21 $ DPL Y 10 dgt $

ADO $ c411 1 0 2 0 MDN SCA Y Y 6197215555 TONE N $
```

C411 01 0 02 00 is now the Primary member of the MADN group 6197215555. A MDN group named “6197215555” is created on the Session Server element manager and user “user2@mordor.com” is added to the group. The DN of user “user2@mordor.com” is cleared (blanked) in the Session Server element manager.

A second line is added with a different DN, 6197215554:

```
NEW $ 7215554 IBN BNR 0 0 619 NILLATA 0 C411  01 0 02 1 SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user3@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user21 $ DPL Y 10 dgt $
```

Now the MDN option is added to this second line specifying a different DN (6197215555) and a treatment (BLDN) for the original DN (6197215554) :

```
ADO $ C411 01 0 02 01  MDN SCA N Y 6197215555 BLDN  $
```

The end result of this is that the DN for C411 01 0 02 01 changed from 6197215554 to 6197215555 on the core and the line is now a member of MADN group 6197215555 on the Session Server element manager. Now, delete the MDN option from this newly added member and specify it's new DN.

```
DEO $ C411 01 0 02 01 MDN 6197215554 $
```

Following the DEO of the MDN option, the DN for C411 01 0 02 01 is changed from 6197215555 to 6197215554 on the core and the line is no longer a member of MADN group 6197215555 in the Session Server element manager. User “user3@mordor.com” will have a DN assignment of 6197215554 on the Session Server element manager.

136.6.2.1.9 NEW, OUT and CDN for MADN

MADN groups may be created and populated using the NEW command.

Examples:

```
NEW $ 7215554 IBN BNR 0 0 619 NILLATA 0 C411 01 0 02 01 DGT MDN SCA Y Y TONE N SIP_DATA
SIP_PACKAGE SIP Lines SIP_URI user1@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION
Nortel Networks.RTP.NC0 SIP_PASSWD user11 SIP_SUBDOMAIN doom.mordor.com $ $

NEW $ 7215554 IBN BNR 0 0 619 NILLATA 0 C411 01 0 02 02 DGT MDN SCA N Y SIP_DATA SIP_PACKAGE
SIP Lines SIP_URI user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel
Networks.RTP.NC0 SIP_PASSWD user11 SIP_SUBDOMAIN doom.mordor.com $ $

CDN $ 6197215554 6197215555 BLDN

OUT $ 7215555 C411  01 0 02 02 BLDN

OUT $ 7215555 C411  01 0 02 01 BLDN
```

A group with type “MDN” and name “6197215554” is created during processing of the first NEW command and user “user1@mordor.com” is

added to that group. The second NEW command adds user "user2@mordor.com" to the same group. The CDN command results in the DN for the MDN group being changed in the core for all members and also the group name changing from "6197215554" to "6197215555" in the Session Server element manager.

On the SS-EM, the OUT command will removed the line/user from the MDN group, and if the user is the last member of the group, the group will also be removed.

136.6.2.1.10 EST, ADD, DEL,CHDN

Huntgroup flowthrough architecture only triggers flowthrough for hunt flavors which can assign service to a HASU line: MLH, DLH, and DNH. MPH can also be used to assign service to a HASU line, however MPH is not supported for SIP line. Other flavors such as CPU, CMG, SIMRING, and BNN are assigned to lines with existing service and therefore trigger no flowthrough and hence no group creation/deletion on the Session Server element manager.

Examples:

DLH:

```
EST $ DLH 6195209998 1FR LATA1 0 SCOT  00 0 00 00 $ dgt SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user1@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user11 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $

ADD $ DLH SCOT  00 0 00 00 SCOT 00 0 00 01 $ dgt SIP_DATA SIP_PACKAGE SIP Lines SIP_URI
user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0 SIP_PASSWD
user21 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $

DEL $ DLH SCOT 00 0 00 01 $

OUT $ 6195209998 SCOT  00 0 00 00 BLDN
```

With these commands, a group is created on the Session Server named "6195209998" (GROUP_DN in query output for these lines) with a type of "DLH" (GROUP_TYPE in query output for these lines). The Session Server group is created when the EST command is processed and user "user1@mordor.com" is added to the group. The ADD command triggers no group creation, but user "user2@mordor.com" is added to group "6195209998" on the Session Server Element Manager. The DEL command removes user "user2@mordor.com" from the group and from the Session Server element manager in general. Finally, the OUT command removes group "6195209998" from the Session Server element manager and also removes user "user1@mordor.com".

MLH:

```
EST $ MLH 6195209998 1FR LATA1 0 SCOT  00 0 00 00 $ dgt SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user1@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user11 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $
```

```
ADD $ MLH SCOT  00 0 00 00 SCOT 00 0 00 01 $ dgt SIP_DATA SIP_PACKAGE SIP Lines SIP_URI
user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0 SIP_PASSWD
user21 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $

CHDN $ SCOT 00 0 00 01 2145200999

DEL $ MLH SCOT 00 0 00 01 $
```

The CHDN command shown above results in the DN change of member SCOT 00 0 00 00 to 2145200999 in the core but no change to the currently blank DN assigned to user “user2@mordor.com” in the Session Server element manager. The user’s DN will remain blank in the Session Server as long as it is a member of a group regardless of DN changes which occur in the Core.

DNH:

```
EST $ DNH 2145200998 1FR LATA1 0 SCOT  00 0 00 00 $ DGT SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user1@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user11 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $ 5

ADD $ DNH 2145200998 2145200997 SCOT  00 0 00 01 $ DGT SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user21 SIP_SUBDOMAIN doom.mordor.com $ DPL Y 10 $ 5

DEL $ DNH 2145200997 SCOT  00 0 00 01 $ bldn
```

Note that the SERVORD+ format requires insertion of GW/EP or LEN in the DEL command for DNH groups. This is normally not required in Core SERVORD.

Only ONE SIP LEN/gw-ep is supported in any EST or ADD command since only one SIP_DATA option is allowed in the options area of the command. Use of more than one SIP LEN/gw-ep in the EST/ADD command will result in command failure.

136.6.2.1.11 CDN

SESM logic will support flow through of change DN requests for SIP Lines, however the CDN command will be blocked for MLH/DLH hunt pilots/ members but will be supported for MADN and DNH group pilot/link/ members (this is a legacy implementation restriction on CDN commands).

Example:

```
NEW $ 7215555 IBN BNR 0 0 619 NILLATA 0 C411  01 0 02 00 SIP_DATA SIP_PACKAGE SIP Lines
SIP_URI user2@mordor.com SIP_CLIENT_TYPE SIP Line SIP_LOCATION Nortel Networks.RTP.NC0
SIP_PASSWD user21 $ DPL Y 10 dgt $

CDN $ 6197215555 6197215554 BLDN
```

CDN commands which modify the DN assigned to the user will ***not*** automatically update a SIP_URI containing directory number information. The use of Directory Number in the SIP_URI value (e.g. 2145209999@nortel.com) is not recommended.

136.6.2.1.12 CLN

A limited OSSGate/SERVORD+ infrastructure is provided to process flowthrough for CLN commands for SIP lines, however the processing is limited to changes between SIP lines only. For CLN of SIP lines, the from_value and to_value in the CLN command must both contain SIP LENS/ endpoints, otherwise the command will fail.

Examples:

```
CLN $ C411 01 0 02 00 C411 01 0 02 01
CLN $ C411 00 0 00 00 C411 01 0 02 01
```

136.6.3 Line Audit :

In this feature, the line audit will also audit the data in Session Server EM. The audit GUI look and feel does not change, except that few checks are added to warn the user of system load. Also the audit output file (both valid and problem files) will have extra information pertaining to the Session Server audit.

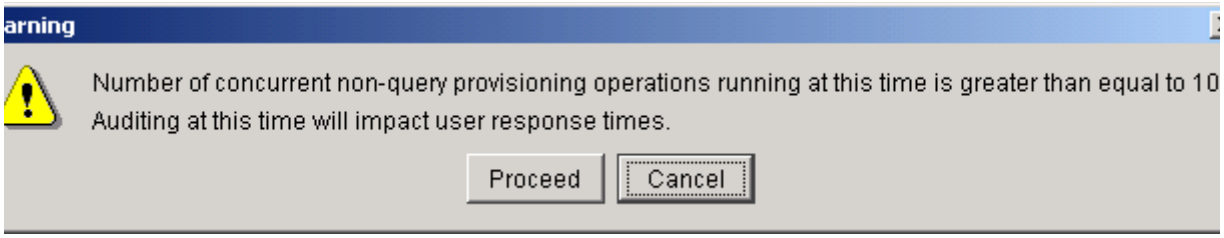
136.6.3.1 Warning Dialogues in Audit GUI

One of the requirements in this feature is to avoid running(atleast warn) line audit when the system is loaded, as the audit might impact more important provisioning activities. In this feature, the manual line audit will check for the system load and warn the user if its not an appropriate time to run audit.

When the user choose line audit from GUI and clicks RunAudit button, the GUI first checks with Audit server if its ready to run the audit. The server does three checks to determine if its ready or not. If any of the three checks is true, then the server will return ‘not ready’ with details to the GUI, which in turn will pop a dialogue box to warn user of system load and gives him a chance to decide if he wants to run the audit at a later time, since running audit has the potential to slow down the system impacting higher priority provisioning activities.

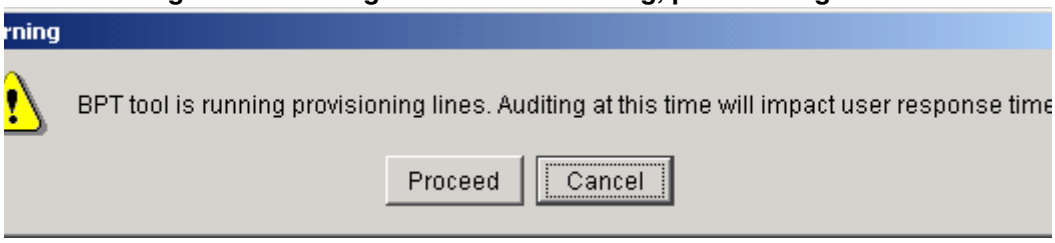
First check done by the server is to see if there are 10 or more concurrent non-read-only operations in progress. If yes, the audit server returns ‘not ready’ with details to the GUI. Shown below is example dialogue box.

Figure 2 Warning if 10 or more non-query type line provisioning in progress



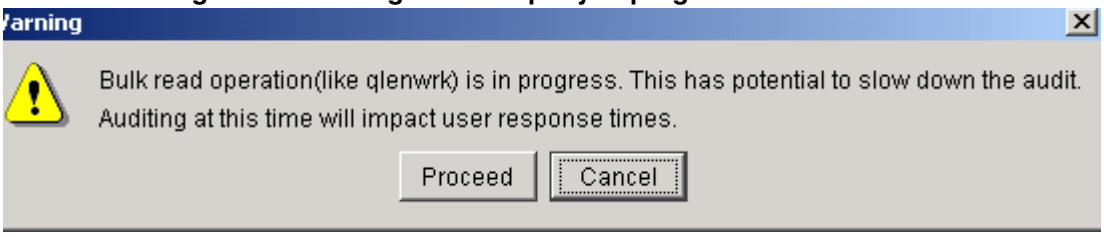
The second check is to see whether BPT tool is running a lines batch operation. If yes, the server returns ‘not ready’ with details to GUI. Shown below is example dialogue box in this condition.

Figure 3 Warning if BPT tool is running, provisioning lines



The third check is to see whether any bulk query operation(like qlenwrk,qdnwrk etc) is already in progress . If yes, the server will return ‘not ready’ to the GUI. Shown below is example dialogue box in this scenario.

Figure 4 Warning if a bulk query in progress before line audit starts



136.6.3.2 Warning in BPT on Audit Running

In addition to the line Audit GUI warnings(2.6.2.1), a check is introduced in BPT tool where it determines if Line Audit is currently running. If yes, BPT tool will warn the user that line audit is in progress and gives the user a chance to run the lines batch later, as the throughput of the Lines batch could be slower due to line audit running.

Screen shot from BPT tool when lines batch is started while line audit is in progress.

***** W A R N I N G *****

Line Audit is currently in progress.

This lines batch may run slower and may also invalidate audit results

Do you still want to proceed with lines batch? <y/n>:

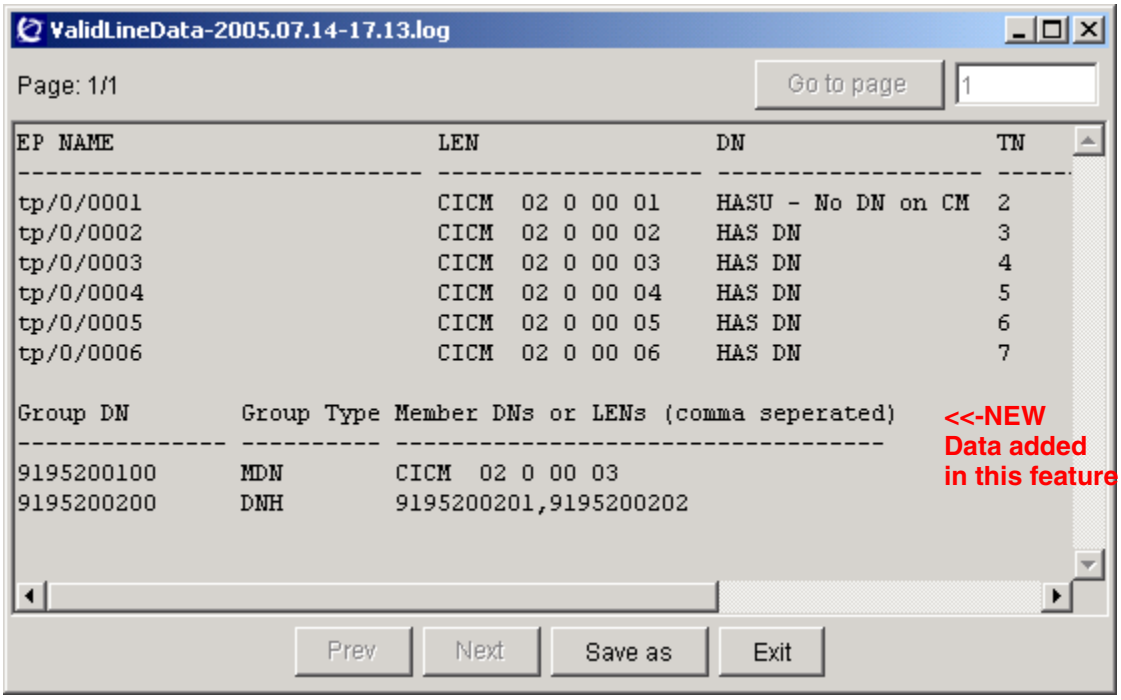
The above warning tells the user that line audit is in progress and perhaps the lines batch should be run after the audit is finished

136.6.3.3 Line Data Audit Valid Data output:

After the line data audit finishes, the ValidLineData.log file will have additional information obtained by auditing the Session Server EM.

The endpoints in GWCEM will be compared with SS EM, the group DN and its member DN information will be compared with the core and the DN to len mapping will also be compared with the core.

In the first screen shot is shown, valid data w.r.t the Session server will be at bottom. In the foll screen shot, the group DN and its type and the member DNs are printed on screen, which is new audit data added by this feature if SIP MGs are provisioned.



136.6.3.4 Line Data Audit Problem Data output:

Shown below is screen shot of problem line data results. The problems could be in following areas

1. Endpoint exists in GWCEM, but not in Session server EM

2. DN associated with endpointId(len) in SS EM, while that same DN maps to different LEN on core

3. group DN in SS EM but that group information is missing in core

4. member DN/LENs in SS EM belonging to a group do not match the member list in that group on core.

New term	Definition

138: Functional Description (FN) A00012242

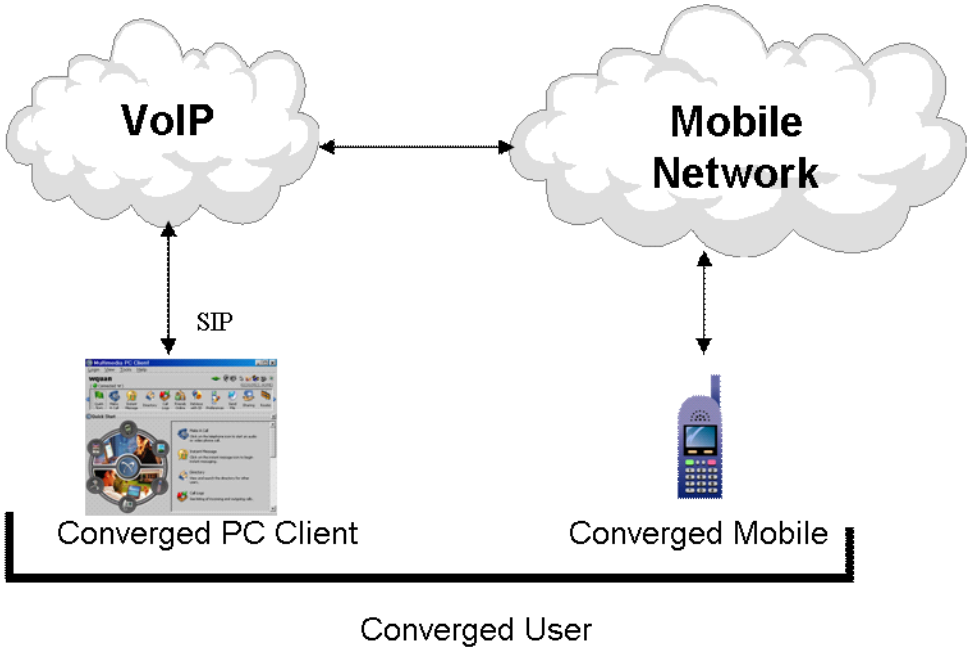
138.1 Feature name and Feature ID

A000122423: TME-CD with GSM Wireless Client, Ph-1: “Mobility for Converged Desktop - MCD”

138.2 Description

The Converged Desktop feature was introduced in previous versions of MCS and enabled subscribers to use their SIP PC Client for the multi-media portion of their communication, while using their existing telephony system for voice.

Figure 1 Mobile Converged Network



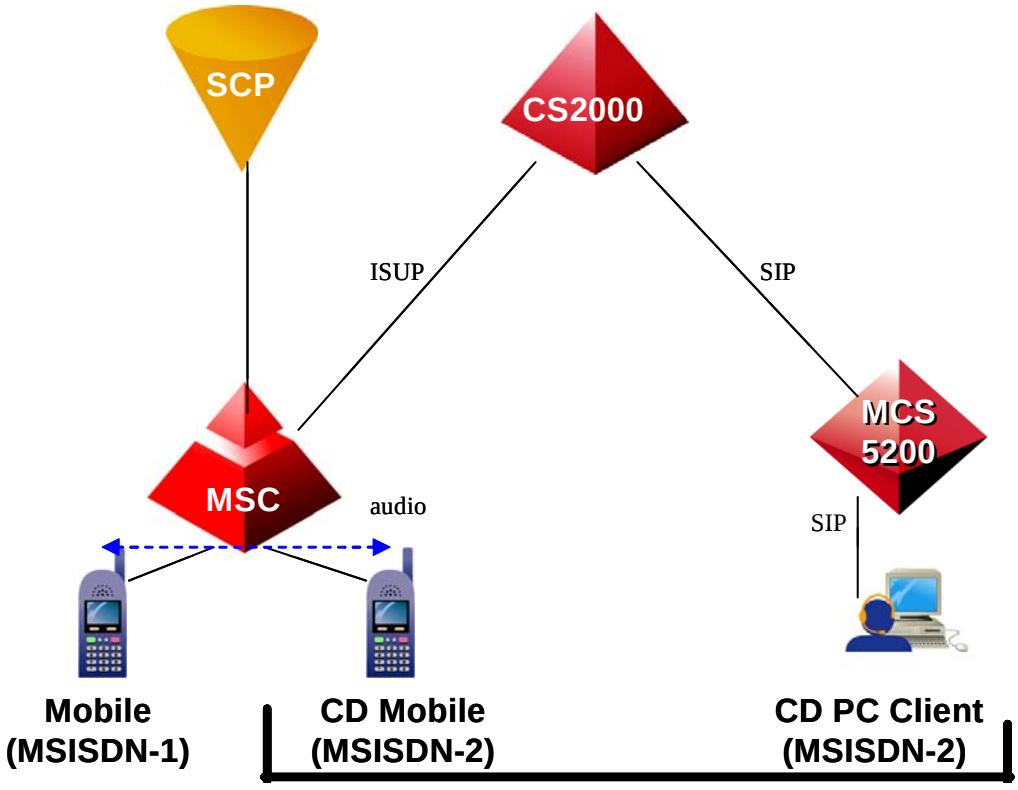
This feature provides a new Centrex service on the MCS application server that enables limited call control of wireless calls from the terminating Converged PC Client, while the audio streams to a preferred audio device in

an existing wireless network. In this phase, the services are limited to terminating services without video.

Generally, the feature sets offered by each network are independent such that mobile features are not integrated with the MCS network. Only within the context of this feature are the networks ‘converged’. Features provided on the mobile network are in no way limited by this feature. The operator should consider feature interactions, as they may intersect on the converged networks. Voicemail is an example of this interaction, as either / both networks can provide a network based voicemail service.

The network component view of the converged networks and the connectivity between the CD Mobile and the CD PC Client is shown in Figure 2.

Figure 2 Network Component Diagram



The mobile network is typically comprised of several MSC (and peripherals for the radio interface) so the illustration is simplified in this regard. The mobile converged phone is illustrated as ‘CD Mobile’ and is also referred to as the preferred audio device throughout this document. The established voice path (audio stream) is between the mobile terminals. The CD PC Client is used to manage calls terminating to CD Mobile.

The only Intelligent Network (IN) node illustrated on the mobile network is the SCP. This is clearly a simplification of the Intelligent Network, and the figure illustrates only the nodes relevant to this feature. The SCP serves as a central point of service logic, which includes the necessary digit manipulation and logic enabling the MCS to later supervise the call. Generally, the IN nodes are not assumed to be Nortel switching nodes.

The MSC is expected to possess SSP functionality to interact with the SCP. In general terms, the terminating mobile will subscribe to a trigger in the AIN terminating call model. Thereafter when a termination attempt is processed, the trigger will be hit, and call processing will suspend on the MSC to query the SCP for service processing. Service logic in the SCP will execute to prefix digits and respond to the query with an analyze_route message to the MSC. The MSC (SSP) will continue processing the call and terminate the call to the CS2000. The MSC (SSP) nodes of the network need not be Nortel switching nodes.

The Nortel CS2000 is a key network component employed to tandem calls between the MCS IP network and the mobile TDM network, and is a required component for this feature. The CS2000 serves as a gateway between the mobile network and the MCS IP network. When this feature is enabled, calls destined for CD Mobile will be routed through the CS2000 and down to the MCS5200 for supervision before being presented to the CD Mobile.

This converged network topology requires overflow route engineering on the CS2000 to ensure mobile calls are properly routed during an IP network outage. The CS2000 is able to detect the SIP trunk status by sending periodic heart-beat messages on the SIP trunk connecting it with the MCS5200. The SIP trunk status could be out-of-service if the MCS5200 becomes network isolated on the IP network or is simply offline for any reason. The CS2000 must be configured to route traffic to an alternate overflow route if the SIP trunk status is detected as out-of-service. The operator should engineer overflow routes on the CS2000 to accommodate the mobile traffic in such an outage on the MCS IP network. The operator should refer to CS2000 documentation for detailed discussions of provisioning this functionality.

This feature is only designed to interact with the clients shown in Figure 2. That is, the CS2000 and the MCS5200 may be hosting other lines and user agents, yet these call-types fall outside the scope of this feature.

Based on PC Client, this feature has been designed for Small to Medium Enterprises with limited access bandwidth, so that audio streams are never exchanged between the PC Client and the network. Once the terminating CD Mobile voice path is established, this feature allows the MCS 5200 to supervise all calls terminating to that CD Mobile via the MCD Client. Thus, the subscriber can use the MCD PC Client to modify the audio stream to the CD Mobile. This is made possible in the MCS IP network because the audio

session can be updated (third party call control) without modifying the audio connection on the mobile network. The functionality provided by the MPC Client will be especially useful in scenarios with several concurrent calls, since the GUI of the MCD PC Client can be more intuitive in managing multiple calls and initiating multi-call features such as conference or transfer.

Provisioning this Centrex service requires configuration on the Mobile Network and the MCS network. As part of the PSTN configuration, a required dial-plan must be established (section 138.3.2 Dial Plans), and a prefix numbering scheme is provisioned by the operator across the network. Mobile CD subscribers will be provisioned on the SCP as fixed extensions of the company they belong to in the Corporate Service, linked to the company's new "non-existent" PBX (MCS). Unless otherwise stated, mobile features enabled on the PSTN are not coordinated with those provided by this service and therefore mobile subscribers can continue to invoke features from the mobile without the MCS5200 knowledge or supervision. This document will later consider only one such feature- voicemail.

On the MCS system, the operator must provision the following prefixes to use this mobility converged service. These can be provisioned on the sub-domain or the subscriber. If both the sub-domain and subscriber have a prefix provisioned, the subscriber prefix will be used. Provisioning is discussed in more detail in section 138.2.12.1 Service Prefix Provisioning.

- Destination Call Leg Return Code (CRD): This is the sum of navigational digits that will be placed in front of the (non CD) destination mobile number for outgoing calls from the MCD client to the mobile network.
- Associated Call Leg Return Code (CRA): This is the sum of navigational digits that will be placed in front of the CD destination mobile number (PAD). This prefix can be used to identify this call leg on the GSM network as a non-chargeable call.

On the MCS network, the operator can assign services and create service packages that expose features to the 'Personal Agent' and enable the feature set at the client. Some services are not compatible with this feature. Logic in the provisioning server will prevent incompatible services from being packaged together in the same service package. Section 20.7.1 Service Compatibility covers these service interactions in more detail.

The services that are supported in the MCD PC Client generally fall into two categories: multimedia services and voice services. Generally, multimedia services are available only to MCS clients. For example, the 'whiteboard collaboration' feature of the PC Client requires both parties to use the MCS PC Client. Multimedia services have no interaction with the mobile network. Multimedia services are supported only between MCS Clients, and can be enabled (and disabled) via the existing service assignment and packaging mechanism by the administrator. The existing behavior of the client is to

render service related buttons only when that service is exposed to the subscriber. That is, the PC Client GUI has dynamic behavior based on the subscriber service package contents. This document assumes these services are enabled.

The following optional services are the only multimedia services supported in this feature. Services not listed will not be supported in this release.

- Collaboration: File Transfer
- Collaboration: Clipboard Transfer
- Collaboration: Web Push
- Collaboration: White Board
- SIP based Instant Messaging

The voice services in the MCD PC Client allow the subscriber to manage calls and invoke call related features. Some voice services will require service assignment and packaging. For example, conferencing requires the service ‘Ad Hoc Conferencing’ and the service package parameter for the ‘maximum number of conference ports’ is enforced in the MCS application server.

The MCD subscriber can perform the following services from the MCD PC Client. Services not listed will not be supported in this release.

- Originate new calls
- Receive incoming calls
- Hold and Retrieve calls
- Switch between several connected calls
- Direct transfer an existing call to another party
- Request a new conference
- Join all calls into a single conference

138.2.1 SIP Client Registration

All features of the MCD PC Client are enabled after successful login to a MCS Application Server. The authenticated login process essentially employs a SIP REGISER transaction to associate the users contact on the application server. Additionally, the client retrieves a service package which itemizes all services and capabilities available to the subscriber and the parameters associated with those services. This section details the registration behavior the subscriber can expect for various client configurations.

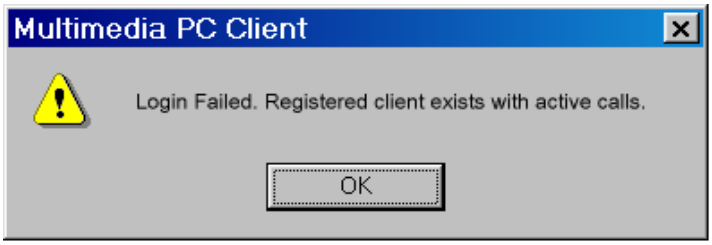
138.2.1.1 MCD Client Login

The mobile converged PC client logic is automatically activated in the Multimedia PC Client if the service package contains the Mobile Converged

Desktop service. Unlike the previous converged-desktop client, once activated the PC Client may not be manually un-converged via the ‘preference’ GUI. The PC Client in the mobile converged mode of operation will be referred to as MCD PC Client within this document.

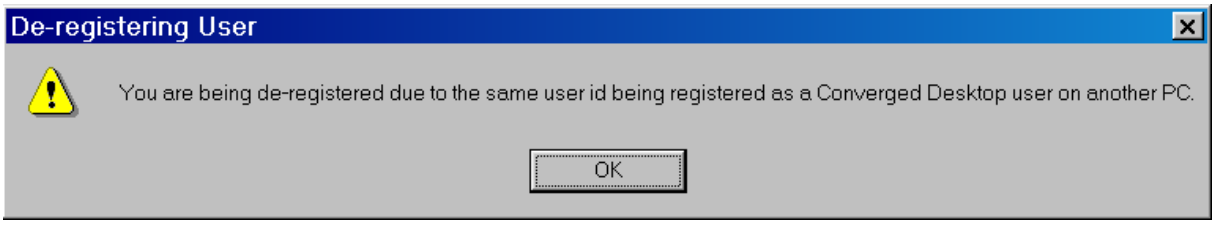
A subscriber should only login a single instance of the MCD PC Client. If the subscriber attempts to register a second instance of the MCD PC Client while calls are in progress, the second registration will be rejected by the MCS application server and the client will indicate to the user that active calls are still in progress

.



If there are no calls in progress when the second instance registers, the first instance will be de-registered. The deregistered client will display a notification to the user as shown in Figure 3.

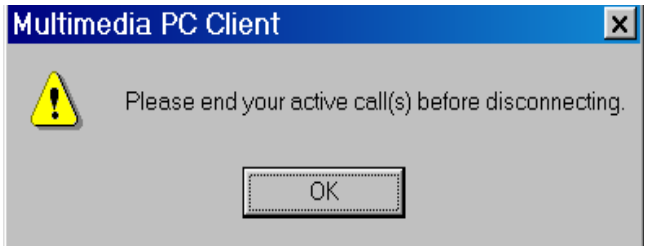
Figure 3 Deregistered on client



138.2.1.2 MCD Client Logout (or Exit)

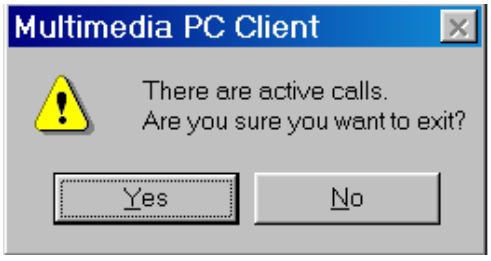
The subscriber may attempt to logout or exit the client at any time. The client logout process involves the typical SIP REGISTER (with a subscriber contact and expires of zero). During a ‘Logout’ attempt with active calls, the MCD PC Client will prompt the user to end active calls before disconnecting (Figure 4). The user can only click ‘OK’ and should manually release any active calls before to proceeding with the logout.

Figure 4 Logout attempt with active calls



During an ‘Exit’ attempt with active calls, the MCD PC Client will warn the user that calls are still in progress. The user can either click ‘Yes’ to release all active calls and shutdown the client or ‘No’ to cancel the attempt.

Figure 5 Exit attempt with active calls



In the event the MCD PC Client becomes network isolated with active calls, the mobile subscriber will lose the ability to manage the existing calls. The best way to cleanup the existing calls is to release the PAD leg on the CD Mobile. The application server will automatically release all calls for the MCD subscriber when the CD Mobile (PAD) leg is released. Additionally, the MCS application server executes periodic call audits to release calls that are apparently stranded. The situation where the MCD client is network isolated or unavailable is discussed in more detail in 138.2.11 Client Unavailable / Calls of Grace.

138.2.1.3 Standard Client Registration

Non converged clients perform a ‘standard’ client registration upon subscriber login. If a subscriber with the MCD service assigned in the service package utilizes a non-converged client (e.g. I200x device), then call terminations to them will be presented to the clients using the existing call forking mechanism at the Application Server and no mobile converged client control functionality (as described in this document) will be provided.

138.2.2 Supported Releases of the Multimedia PC Client

The MCD PC Client functionality is only supported in the 4.1 release of the PC Client.

138.2.3 Call Origination Behavior

This section assumes the MCD PC Client is registered and the corresponding CD Mobile is actively available on the mobile network for originating calls. The subscriber can originate calls either from the CD Mobile or the MCD PC Client. The following sections consider the behavior for both scenarios. Detailed call processing (signaling) details are deferred to a later section.

138.2.3.1 MCD PC Client Origination / Click-to-call

Even though the MCD PC Client is not used for voice, the subscriber can use the MCD PC Client to originate calls. This call scenario is also referred to as 'click-to-call' and behaves much like a direct transfer. In the click-to-call scenario, a call leg to CD Mobile is first established and immediately followed by the PAD being transferred to the destination mobile (MSISDN-2). All calls originated from the MCD PC Client employ the click-to-call mechanism.

The basic origination initiated on the MCD Client is performed by clicking 'New Call' and providing the address of the terminating mobile (MSISDN-2). The client will establish a secure HTTP connection (via SSL) to the Personal Agent to initiate the call to the MCS application server. Upon initiating the click-to-call, the MCD PC Client displays a call window similar to that shown in Figure 6. Call originations may be abandoned on the MCD Client.

Figure 6 Click-to-call Outgoing call window

Additionally, the click-to-call origination can be initiated directly from the Personal Agent web application. However in this case, the subscriber cannot cancel (abandon) the call attempt like on the MCD PC Client.

The mobile converged service suspends the MCD subscriber from making or receiving additional calls while a click to call outgoing call attempt is 'In Progress'. The MCS Session Manager will reject subsequent outgoing call attempts indicating that active calls are still in progress, and, likewise, the MCS Session Manager will also reject any incoming calls by responding with a 600 Busy Everywhere SIP response. Thus, once call is originated on the MCD PC Client, it will not be possible to originate another call from the client or terminate another call to the client until the initial call is either answered or terminated

138.2.3.2 CD Mobile

When the PAD originates a new call, the wireless network (MSC) will route the call without interaction with MCS application server. The MCD PC Client will not be supervised from the wireless network for originating call scenarios from the PAD.

138.2.4 Call Termination Behavior

This section assumes the MCD PC Client is registered and the corresponding CD Mobile is available on the mobile network for receiving calls. When a call attempt is made to the CD Mobile, the MCS application server will present the call to the registered MCD PC Client. The PC Client will to display a call dialog GUI indicating a call is being received at the same time the CD Mobile starts ringing. This section discusses the MCD PC Client behavior for various terminating scenarios. Detailed call processing (signaling) details are deferred to section 138.3.4 PAD Terminated Scenarios.

MCD PC Client behavior depends on the subscriber assigned services. Thus, the MCD PC Client GUI may display icons that enable various features such as Reply with Instant Messaging, Transfer, or Conference. Recall, it is possible to limit the features exposed on the client by provisioning a service package without collaboration features, conferencing, etc. The following sections illustrate the client GUI behavior in the standard theme with all supported services enabled.

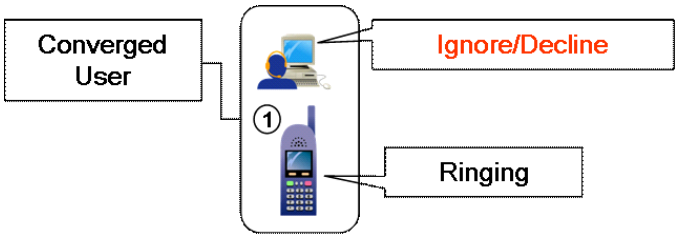
138.2.4.1 Call Window Before Answer

Before a call is answered on the CD Mobile, the MCD PC Client displays a call window similar to that shown in Figure 7. When the call is presented, a Picture-ID and the calling party number are provided. A custom Picture-ID is only available if the other end is an MCP user and has assigned such a picture in Preferences section of the Personal Agent. Otherwise a default Picture-ID[1] will be used. Additionally, the subscriber may have the option to initiate multimedia services such as SIP Instant Messaging[2]. Recall, these services may not be exposed to all subscribers.

[1]The default Picture-ID can be modified in a custom PC Client theme.
[2]SIP Instant Messaging is not integrated with mobile network SMS messaging in this release.

Figure 7 Initial Inbound Call to MCD PC Client

Note the ‘Answer’ button is inactive. Thus, the audio options available for this pending call simply allow the subscriber to immediately ignore or decline the call.



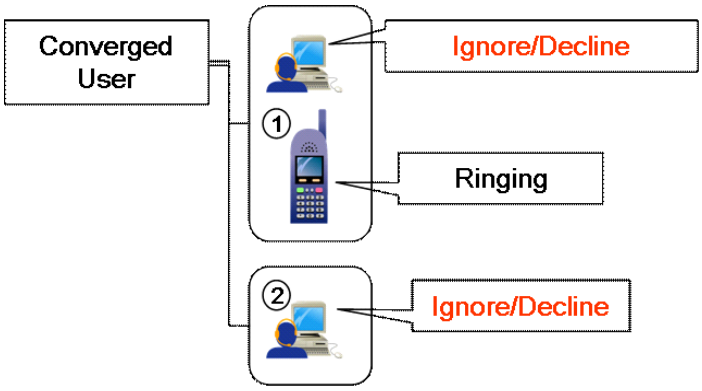
When the ‘Ignore’ button is pressed it would stop the client from ringing while the application server would continue executing any terminating services for the call. That is, terminating service logic is executed to route advance to another destination or voicemail. After all terminating services completed on the application server, it would release the call with cause and the mobile network could execute terminating services. Within the context of this feature, the Ignore button affects all user network contacts. This behavior, while typically customizable from the “Users Preference GUI –> Miscellaneous –> Ignore Buttons” menu, will not be customizable for the MCD PC Client.

The decline option results in releasing the call such that terminating services on the application server would cease for the call. The MCS application server would release the call with cause and the mobile network could execute terminating services.

The ‘Answer’ button remains disabled on the MCD PC Client until the CD Mobile has answered. That is, the initial call attempt to the CD Mobile can not be answered from the MCD PC Client. Subsequent calls can be answered from the MCD PC Client.

In the case of two or more simultaneous incoming calls prior to answering the CD Mobile, the ‘Answer’ buttons on all incoming call windows is disabled as shown in Figure 7. The first incoming call will be answered upon answering the CD Mobile, and the call window for that call will appear as shown in the following section. Additionally, the ‘Answer’ buttons on any remaining call windows will be enabled, and these remaining calls will be handled as subsequent incoming calls in the multiple call scenario described in section 138.2.5.1 Call Waiting.

Aside from the behavior of the ‘Answer’ button, multiple incoming pending calls will exhibit behavior similar to the initial call.



138.2.4.2 Call Window After Answer

An initial call can only be answered on the CD mobile. Thus, to accept this initial call the CD mobile answers the call. Once the call is answered on the mobile, the PAD leg is established. Subsequent calls may be answered from the PC client.

The MCD PC client call window updates after the CD mobile answers similar to the illustration in Figure 8. The MCS application server signals the client by means of a SIP message to update the GUI with new audio options

Figure 8 Initial call is answered on MCD PC client

The only supported audio options for answered calls are listed below.

Audio options available on answered call	
New Call	Used to place a new call. Clicking 'New Call' will implicitly (local) Hold any existing established calls.
Hold / Retrieve	The user can hold and retrieve the call from the MCD PC Client (local hold). However, the user cannot initiate a local hold if the call is already in remotely held. This scenario is referred to as dual-hold, and is not supported.
Conference	Initiates an audio conference. Established calls will be placed on local hold until conference is joined.
Transfer	Initiates a direct transfer of the established call to another destination.
Hang Up	Releases the established call. The CD Mobile call leg will remain established if other calls are on Hold by the MCD PC Client.

Assuming the originator is an MCS SIP subscriber, the following multimedia capabilities must be provisioned by the administrator to be utilized from the terminating MCD PC Client.

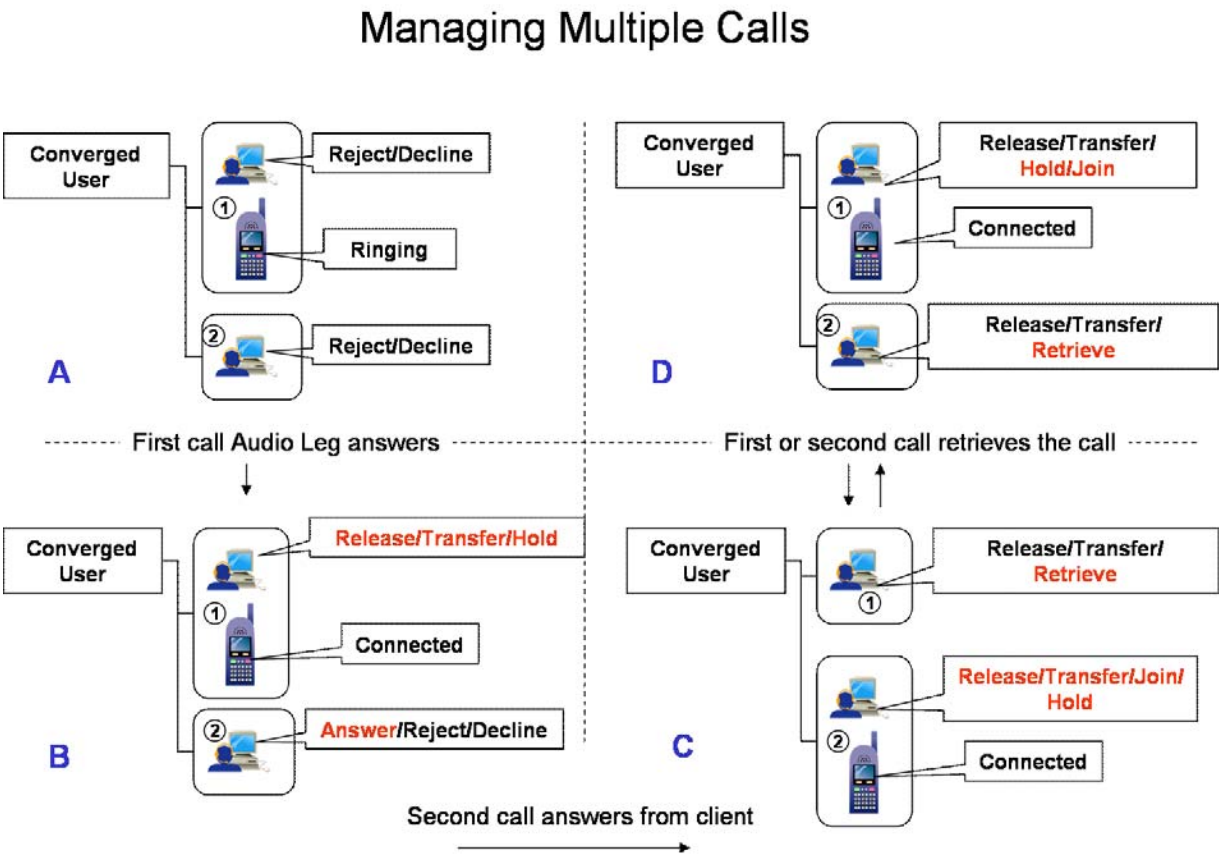
Multimedia capabilities available between MCS SIP clients	
Picture Calling Line Id	Shows a picture of the other party involved in the call
File Transfer	Allows the user to transfer files between MCS PC Client
White Board sharing	Allows the user to establish a White board collaboration session between MCS PC Client
Clip Board Transfer	Allows the user to send the 'clipboard' to another MCS PC Client
Web Co-browsing	Allows the user to push a web page to another MCS PC Client
Instant Messaging	Allows the user to establish SIP Instant Message session between MCS PC Clients
Presence state indications	The presence state of the MCD PC Client is monitored, while the state of the MCD Mobile (PAD) is not. On-the-phone presence is not supported.

138.2.5 MCD Multimedia PC Client with Multiple Calls

This feature introduces new behavior in the MCD PC Client to assist managing multiple established calls and call waiting scenarios. The MCD PC Client uses the PAD as the only audio device and therefore can only support one active voice conversation while the remaining established calls are placed on hold. Thus, the MCD PC Client now provides an interface to juggle several calls on behalf of the PAD.

An illustration summarizing multi-call PC Client behavior is shown in Figure 9. Each quadrant represents a scenario with two calls. The PAD is indicated by the mobile phone icon, and the features available to each call leg are shown in a box next to each.

Figure 9 Managing Multiple Calls



The quadrant labeled ‘A’ illustrates two incoming calls coming into the MCD PC Client, and the PAD has not yet answered. The PAD is ringing for the first inbound call attempt, and is therefore grouped together with the first call leg.

Just as the PAD answers, the transition to quadrant ‘B’ occurs. With the audio stream now established to the PAD, the MCD PC Client GUI is updated to reflect the functionality available to the converged user. The first call leg is associated to the PAD, and can now Hold, Release or Transfer the call from the MCD PC Client. The second call continues to ring, but the call can now be answered from the MCD PC Client. These new options are indicated in the figure with an orange color.

Assuming the second call leg is answered from the MCD PC Client, the transition to quadrant ‘C’ occurs. If the first call leg is not already on hold, upon answer the MCD PC Client will automatically place the first call leg on local hold. The MCS Session Manager will then exchange the audio stream to establish voice-path on the second call leg. Since the audio stream at the PAD is now established on the second call leg, the PAD is re-grouped to the second call leg in the figure. With multiple calls now active, the PC Client offers the

ability to establish a conference by introducing the ‘Join’ button on the established (PAD) call leg. If the user creates such a conference, all active call legs will reduce to a single call leg to the conference server (not shown). Additionally, the user may (direct) transfer this call from MCD PC Client to an alternate address.

The user can alternate between locally held calls from the MCD PC Client. The transition to quadrant ‘D’ indicates this behavior at the client. The MCS Session Manager will exchange the audio stream to the PAD to associate the single established call, while the remaining calls will be placed on local hold. At any time the converged user can ‘Join’ the calls into a single conference.

138.2.5.1 Call Waiting

Call waiting is the ability to present incoming calls while already engaged in a conversation. This section discusses how the subscriber can handle these subsequent calls. When a subsequent call is presented to the PC client, the available options are ‘Answer’, 'Ignore', 'Decline' or 'Reply with IM'. These options are similar to those presented on the initial call with the exception of the ability to answer the new call. The screenshot in Figure 10 illustrates these options.

Figure 10 Second inbound call to MCD PC Client

Audio options are similar to the pending call behavior as described in 138.2.4.1 Call Window Before Answer. There is no modification of the active CD Mobile (PAD) call leg.

If the subscriber chooses to answer the new call, the initial call is automatically placed on local hold by the MCD PC Client, and the audio will be established between the CD mobile and the new caller.

138.2.5.2 Joining Multiple Established Calls into Conference

When a subscriber already has an active call in progress and multiple calls on local hold, the converged PC client offers the ability to join these calls into conference. That is, the ‘Conference’ button will transition to a ‘Join’ button when multiple simultaneous calls are present. Note the ‘Join’ button in the active call GUI as shown in Figure 11.

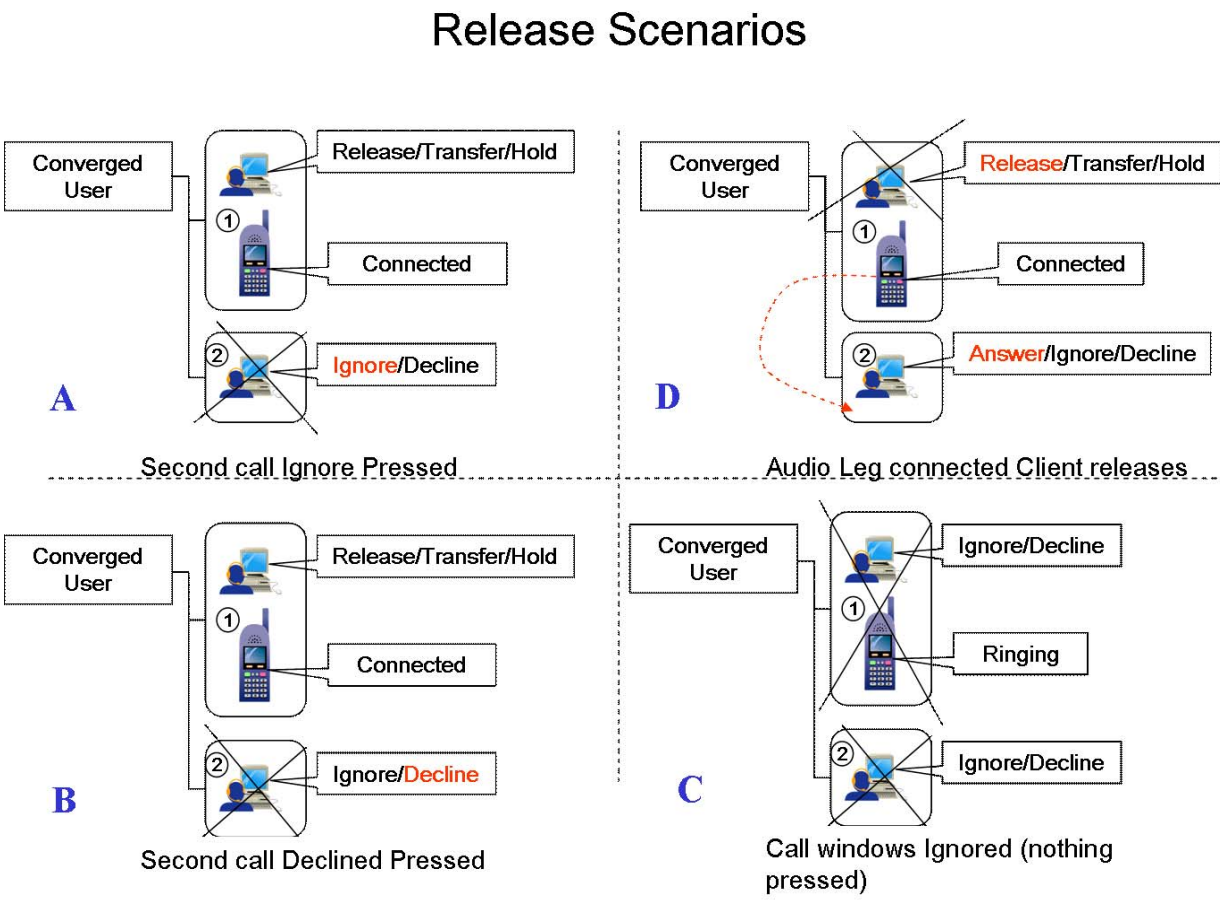
Figure 11 Active Call

If the subscriber joins the calls into an audio conference, all the call dialogs will reduce to a single call dialog to ‘Conference’. A maximum number of simultaneous calls are enforced on the MCS application server during call processing with the exception that the conference leg does not count against the maximum call limit while joining calls into a conference.

138.2.6 MCD Multimedia PC Client Release

This section considers the MPC Client behavior when calls are released. An illustration summarizing multi-call MPC Client release behavior is shown in Figure 12. Each quadrant represents a scenario with two calls. The PAD is indicated by the mobile phone icon, and the features available to each call leg are shown in a box next to each.

Figure 12 Release scenarios



The quadrant ‘A’ illustrates the scenario when a call is already established on the PAD and a subsequent call attempt is pending. The subscriber then chooses to ignore the second incoming call by clicking the ‘Ignore’ button. The Ignore function on the application server allows remaining terminating services to be executed, such as CPL. However, in the absence of CPL, the ignore will result in releasing the call attempt on the mobile network. The call released may not be forwarded to voicemail on the mobile network. For signaling details of this call processing scenario please refer to 20.3.4.2 Call Ignore from MCD PC Client.

Similarly, quadrant ‘B’ illustrates a subsequent pending call attempt. However, in this scenario the subscriber chooses to decline the call by clicking the ‘Decline’ button on the call window. The decline function on the application server does not allow remaining terminating services to run, and the call is immediately released. The call released may be forwarded to voicemail on the mobile network. For signaling details of this call processing scenario please refer to 20.3.4.2 Call Ignore from MCD PC Client.

The scenario shown in quadrant ‘C’ is a simple one, yet its significance can not be overlooked. The scenario involves two pending call attempts where the subscriber chooses to not press any buttons. Perhaps the subscriber is not physically at the PC Client at the time these call attempts are being made. Regardless, a couple of important topics to consider here are call timers and forwarding to voicemail. Typically a call attempt timer would expire (e.g. ISUP timer T9) and release the call with cause. The MCS application server will implement a timer to release these ignored call attempts with a cause. The mobile network may execute additional terminating services to handle the release with cause. For example, forward these unanswered calls to a voicemail system in the mobile network.

The release scenario in quadrant ‘D’ illustrates PC client behavior when the PAD leg is released while another pending call attempt is presented. When the user clicks the ‘Hang Up’ or ‘Stop’ button on the active call window the first call will be released, and the PAD would then be associated to the second call. However, the voice path would not be established until the ‘Answer’ button is pressed on the second pending call window

138.2.7 Direct Call Transfer

The MCD PC Client can perform a direct call transfer once the call is answered on the CD mobile. As part of the call transfer operation the PC client will automatically put the callers on local hold before transferring to the target party. The consult transfer functionality is not supported in this release.

138.2.8 Conference Calls

Only after an initial call is established can the MCD PC Client initiate a conference call and join multiple calls into a conference. Pending calls can not be joined into conference.

138.2.9 Hold / Retrieve

The MCD PC client control window provides the ability to initiate a hold for the call should that call be active, conversely a retrieve option (same button) is available should the call already be on hold.

The client will instigate the holding of the active call leg by means of a SIP INVITE to the Application Server with an SDP containing the following headers:

`c=`**`0.0.0.0`**`, specifying 0.0.0.0 as the IP address for the audio connection`

`m= audio 50010 RTP/AVP` **`0`** `8 18 110 111, specifying 0 as the port for the audio connection`

A held leg can then be subsequently retrieved by the client again sending a SIP INVITE but with a valid c= line. This will cause the Application Server to re-bridge the media via use of re-INVITEs.

If the MCD subscriber has 'music on hold' in their service package then this feature will apply as appropriate in call hold scenarios.

138.2.10 Call Logs

Call logs provide the subscriber with a record of all incoming and outgoing calls. The PC Client will locally manage these call logs, as opposed to Network Call Logs (NCL) feature which resides on the Personal Agent. Calls may be originated from the call logs and will behave as described in 138.2.3.1 MCD PC Client Origination / Click-to-call.

138.2.10.1 Inbox

Inbound call attempts are recorded in the Inbox. The ability to successfully re-dial a caller from this call log depends on the calling line id provided by the adjacent switch (CS2K). The prefix (CRD) introduced in this feature will automatically be prefixed to the outgoing address to assist in routing.

138.2.10.2 Outbox

Only outbound call attempts made from the MCD PC Client are recorded in this Outbox. Outbound call originations from the PAD will not be recorded in this log (or the NCL).

138.2.11 Client Unavailable / Calls of Grace

Previous sections have described the PC Client behavior when both the converged PC Client and the converged Mobile are actively available and how the feature is then utilized. This section will focus on the feature behavior when the client is unavailable or transitions between available and unavailable. In this context ‘unavailable’ would mean the client is non-accessible due to network isolation or simply unregistered. In addition, the concept of the ‘call of grace’ will be presented, along with how these calls are handled on the application server.

Let us begin with a couple of simple scenarios. One simple scenario occurs when the subscriber is not logged in on a PC Client and the CD Mobile is available. Then mobile calls will continue to be routed back to the mobile network, where mobile terminating services may execute. Another simple scenario is when the CD Mobile is unavailable (maybe out-of-area or turned off) and the PC Client is registered. The PC Client does not have audio capabilities, and the PAD leg will not be established. These are the trivial cases not only because they involve only an initial call, but also because part of the converged client was unavailable.

More complicated scenarios can be constructed when the client transitions between active and inactive. Recall, for this feature the mobile network is configured to route calls to the MCS5200 by triggering service logic in the SCP. Thus, terminating services will be executed at the application server before being processed in the mobile network. This introduces the possibility of latency during call setup. To address this, the application server implements

a mechanism of detecting the PC client network connectivity and minimizing call latency. That is, all calls will be presented to the converged PC client via a SIP INVITE. In order to provide a consistent interface between the application server and the PC Client, irrespective of whether this is a new call or a subsequent call in a multi-call scenario, the client will auto-answer all initial INVITE requests received. This does not mean that the client has indicated that call should be answered; it simply means that the client has initiated a control window for this session and is ready for further instruction from the Application Server. The auto-answer approach simplifies the notification of the client when an initial call has been answered at the MCD mobile, and makes the detection of an isolated client far faster. The detection of an isolated client is faster since the Application Server will shorten the number of re-transmissions of the INVITE to four attempts (equaling 4 seconds) as the client should be auto-generating a 100 Trying provisional response followed by a final 200 OK response if available. The 100 Trying is the first response received by the Application Server to the INVITE and, in effect, indicates the client active and triggers the Application to cease retransmission of the INVITE request. The following examples discuss this behavior.

For example, it is possible for the PC Client to login after a non-CD call has already been established on the CD Mobile. Further assume subsequent call attempts to the converged subscriber occur. When the application server executes this feature as part of its terminating services, it will now present these subsequent calls to the newly registered PC client and create a new PAD leg. Thus, when the client is unregistered all call attempts will be directly presented to the CD Mobile. However, once the client is registered the application server must assume the client is available and attempt to present the call to the client (expecting the auto answer 200 OK from the client). The application server will process this as an initial call described in section 138.2.4 Call Termination Behavior.

Similarly, it is possible for the PC Client to become isolated after calls were established on the CD mobile. Further assume a subsequent call attempt to the converged mobile occurs. Since the MCS application server is aware of the initial established call, the application server does not modify the voice path until after the user clicks ‘Answer’ on the PC Client. The application server assumes the client is accessible and will transmit an INVITE expecting an auto-answer from the client. However, in this case the timer expires after four seconds, and only then does the application server route the call back to the mobile network. Once the application server detects the client is isolated (with established calls), an internal flag is set to store this isolated status. This flag is later observed when subsequent call attempts occur. When subsequent calls attempts occur and the client has previously been detected as isolated, most of these subsequent calls will be directly routed back to the mobile network to avoid the extra four second latency.

For the scenario when the application server has already detected an isolated client, the application server can be engineered to present one of every N subsequent call attempts to the PC client. These calls-of-grace will be presented to the PC client to test the client network connectivity. If the client network connectivity is restored, the multi-call behavior will resume as described in section 138.2.5 MCD Multimedia PC Client with Multiple Calls. The term call-of-grace refers to the scenario when the MCS application server presents a call to the PC Client even when the status of the MCD PC Client is assumed to be isolated. In this context, that one call attempt of N is considered a call-of-grace. The call-of-grace may involve longer call setup latency when the client remains isolated. The value of N is configured through the System Management Console as shown in section 138.2.12.7.1 CallOFGraceInterval. It must be a positive number (default=5), where N=0 deactivates these call-of-grace attempts.

When the MCD PC Client is registered and used to terminate mobile calls, limitations may apply that enforce a maximum number of simultaneous calls supervised at the MCS application server. This limits the number of simultaneous calls that are placed on local hold, or joined into a single conference. The calls routed directly to the mobile network do not count against this maximum number of calls as they are being handled by the CD mobile directly. Incoming call attempts from the mobile network that exceed this threshold will be rejected on the MCS application server (SIP 486 Busy Here).

Call audits occur on the MCS application server to verify established calls are still valid and to provide a mechanism to detect and release network resources that appear stranded. If the call has a Mobile call leg associated to it, the call audit will be forwarded on to the CS2000. If the call does not have a mobile call leg associated and fails the call audit, the application server will release the call to free network resources.

138.2.12 System Configuration and Provisioning

138.2.12.1 Service Prefix Provisioning

As part of the proposed prefix numbering scheme, the operator has to provision the following numbers for each domain to be used by the wireless converged service.

Destination Prefix (CRD): This is the prefix that will be placed in front of the destination number for outgoing calls from the MCD client.

Audio Device Prefix (CRA): This is the prefix that will be placed in front of the destination number for click to call scenarios from the MCD client.

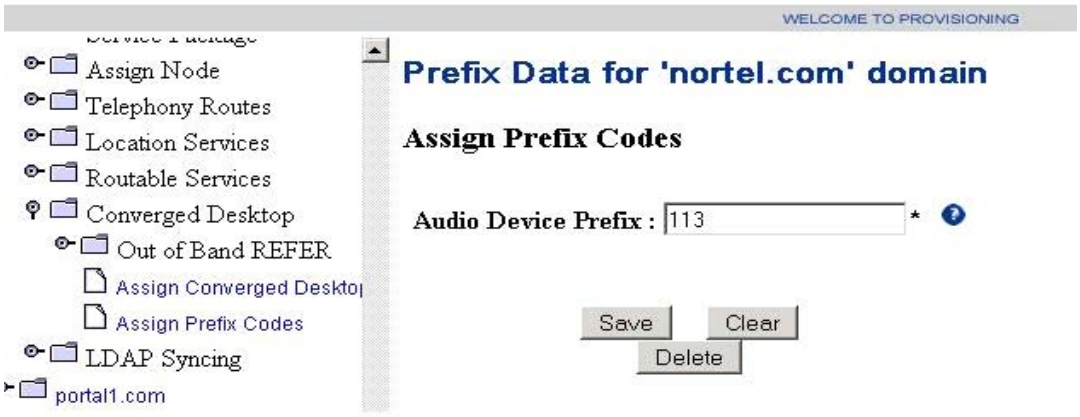
These numbers will be provisioned for each domain/sub-domain that will provide this service. The service on the MCS application server will

automatically insert these prefixes before translations are executed. Thus, it is important that the domain administrator has verified that translations do not exist that may conflict with this dial plan. If translations exist that match the CRA/CRD prefixed destination, calls may be misrouted.

138.2.12.1.1 Audio Device Prefix

A new option called “Assign Prefix Codes” will be added to the Converged Desktop Menu in the provisioning client to provision the audio device prefix.

Figure 13 Provisioning prefix codes



The following new methods will be added to the OPI interface to provision these prefixes. These methods will be added to the existing ConvergedDesktopServiceMgr interface.

```
/**
    * Adds the Prefix data for the mobile converged Service using the
Domain as the key
   * @param String domain, the domain to which the service data belong.
    * @param String domPrefixData, the new service data
   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
    * store is not available.
    */
   public void assignDomainMCPrefixData(String domain, String
domPrefixData) throws ProvisionException;

   /**
```

```
    * Returns the domain prefix data for the mobile converged Service
using the Domain as the key

    * @param String domainID, the domain to which the service data
belong.

    * @param String domPrefixData, the new service data

   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,

    * a duplicate object exists in the data store, a dependency exists
in the data store or the data

    * store is not available.

    */

   public String getDomainMCPrefixData(String domain) throws
ProvisionException;

     /**

    * This method is used for removing prefix data associated with a
domain for the mobile converged service

    * @param String domain, domain from which the service data needs
to be removed.

   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,

    * a duplicate object exists in the data store, a dependency exists
in the data store or the data

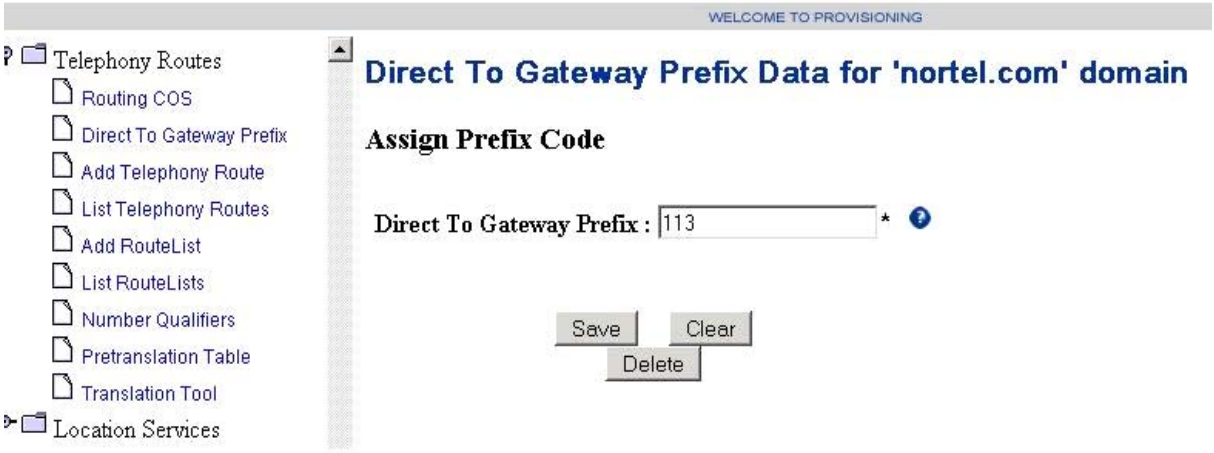
    * store is not available.

    */

   public void removeDomainMCPrefixData(String domain) throws
ProvisionException;
```

138.2.12.1.2 Destination Prefix

A new option called “Direct To Gateway Prefix” will be added to the Telephony Routes menu in the provisioning client to provision the destination prefix or the direct to gateway prefix.



The following new methods will be added to the OPI interface to provision the direct to gateway or the destination prefix. These methods will be added to the existing TelephonyRouteMgr interface.

```
/**
    * This method is used to assign the DirectToGW service prefix data
to the domain
    * @param String domain, the domain name
    * @param String domPrefixData, the prefix data
    * @throws ProvisionException, if there was any problem retrieving
the
   *                        telephony Route information due to the data
   *                          store not being available or invalid data
    *                               being passed in
    **/
   public void assignDirectToGatewayPrefixData(String domain, String
domPrefixData) throws ProvisionException;
    /**
    * This method is used to get the DirectToGW service prefix data of
the domain
    * @param String domain, the domain name
    * @returns String domPrefixData, the prefix data
```

```
    * @throws ProvisionException, if there was any problem retrieving
the
   *                          telephony Route information due to the data
   *                            store not being available or invalid data
    *                                 being passed in
    **/
   public String getDirectToGWPrefixData(String domain) throws
ProvisionException;
    /**
   * This method is used to remove the DirectToGW service prefix data
of the domain
    * @param String domain, the domain name
    * @throws ProvisionException, if there was any problem retrieving
the
   *                          telephony Route information due to the data
   *                            store not being available or invalid data
    *                                 being passed in
    **/
```

138.2.12.2 Outbound Translations

This section provides an overview of the basic provisioning required on the MCS to route an outbound MCD PC Client originated call to the wireless network. Essentially two routes will need to be defined:

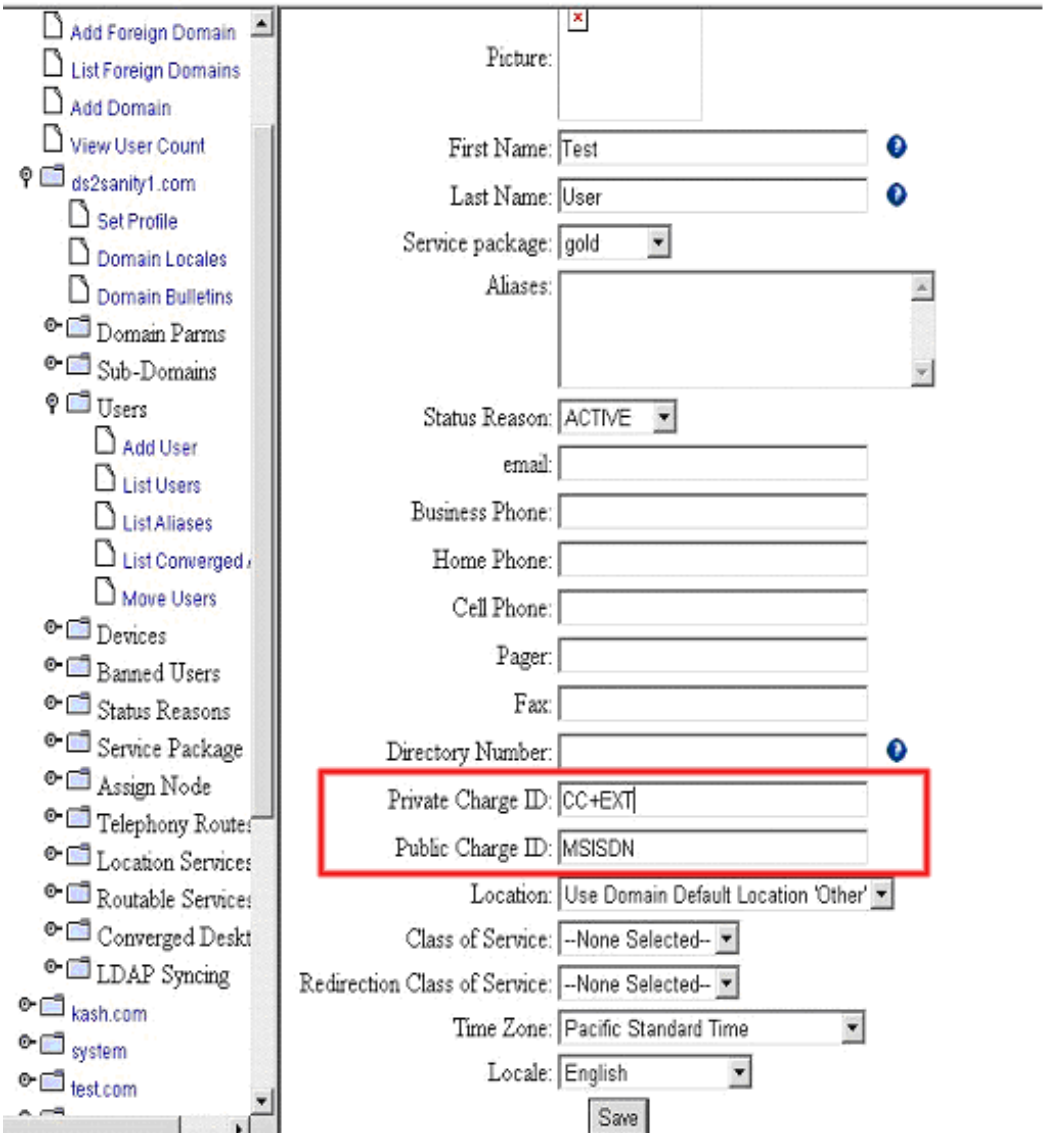
- Private route to the CS2000 – Used when signaling the destination mobile.
- Public route to the CS2000 – Used when signaling the CD Mobile (PAD).

The Mobile CD service will insert the prefixes automatically for the call. The routes are necessary for delivering the correct charge id (public/private) to the CS2000. The routes have to be based on the CRA/CRD values for each domain. A private route based on the CRD is required to send the private chargeid of the user i.e. CC+Ext as the calling party. A public route based on the CRA of the domain is required to send the public charge id of the user, i.e. MSISDN as the calling party.

The private and public charge ids for a user can be provisioned from the user details page in the provisioning client. From the above figure, the private charge id will be used when signaling the destination mobile and the public charge id will be used when signaling the CD mobile.

Provisioning screen shot of the user details page. The user's MSISDN should be provisioned as the public charge id and CC+Ext should be provisioned as the private charge id.

Figure 14 Provisioning subscriber charge IDs



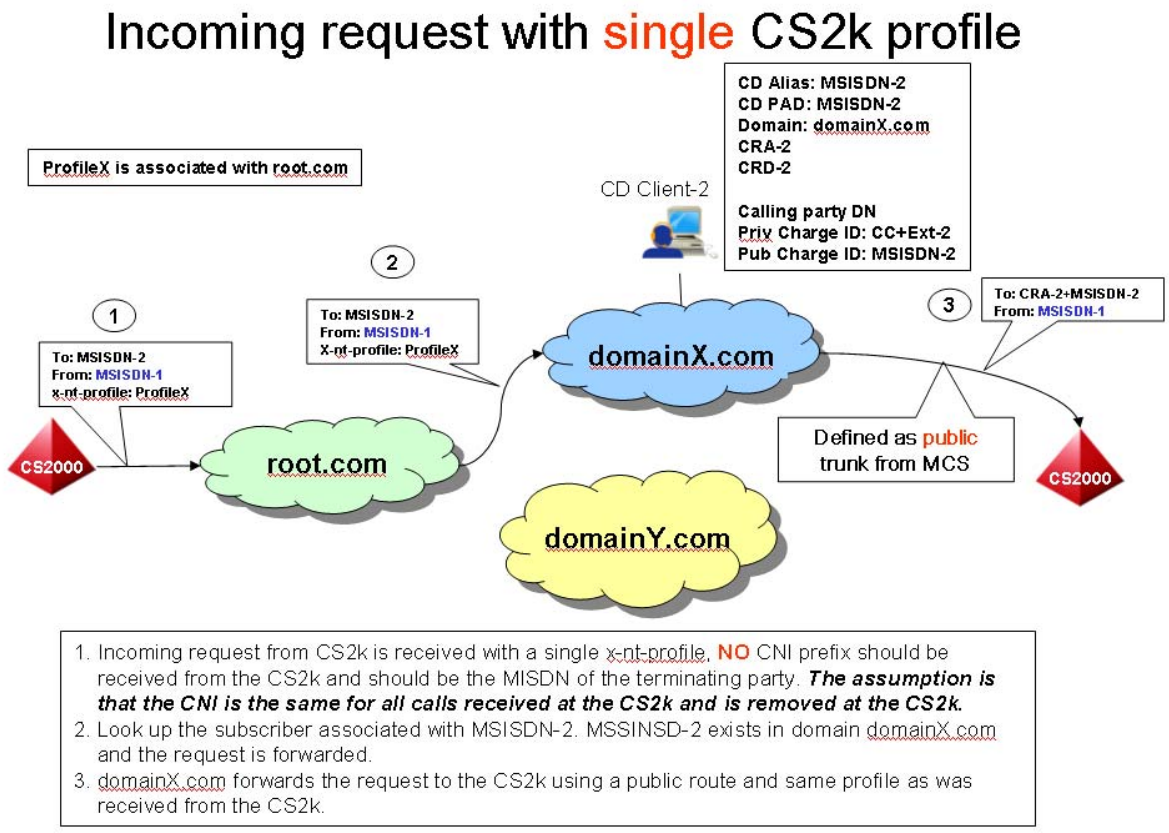
138.2.12.3 Inbound Translations

This section provides an overview of the basic provisioning required on the MCS to route an inbound call to a MCD subscriber.

138.2.12.3.1 Incoming Request with Single CS2K Profile

The following figure illustrates a call flow when there is only one CS2000 profile for all incoming requests. No translations are required in this case since the CNi is removed by the CS2K.

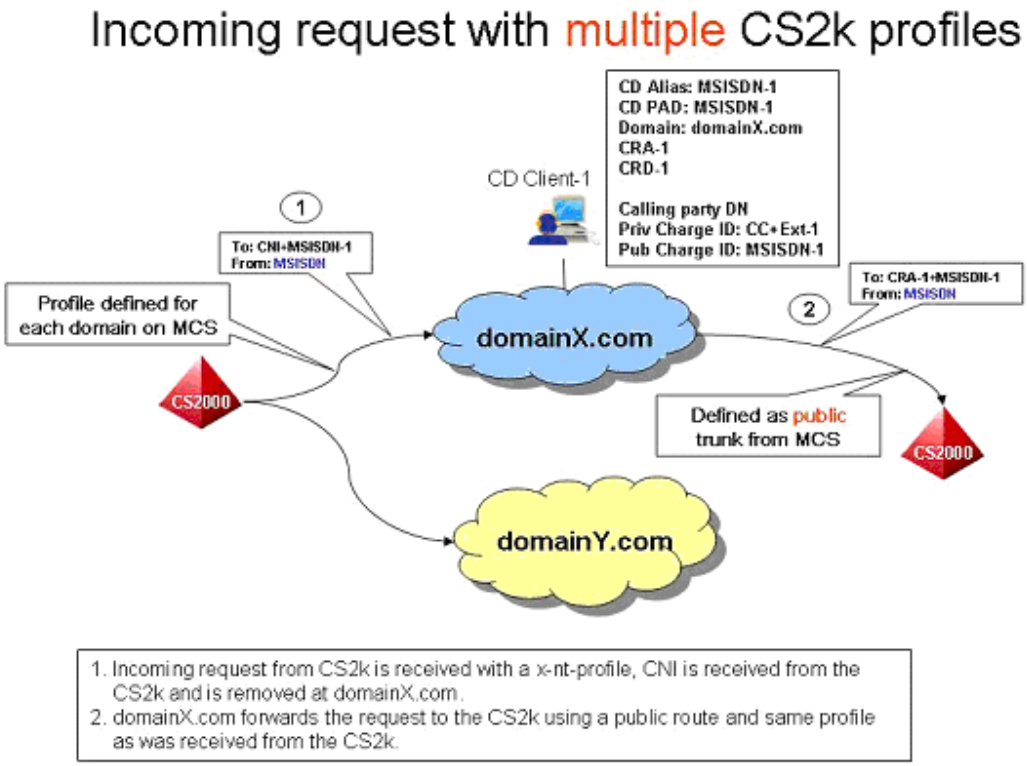
Figure 15 Incoming request with single CS2000 profile



138.2.12.3.2 Incoming Request with Multiple CS2K Profiles

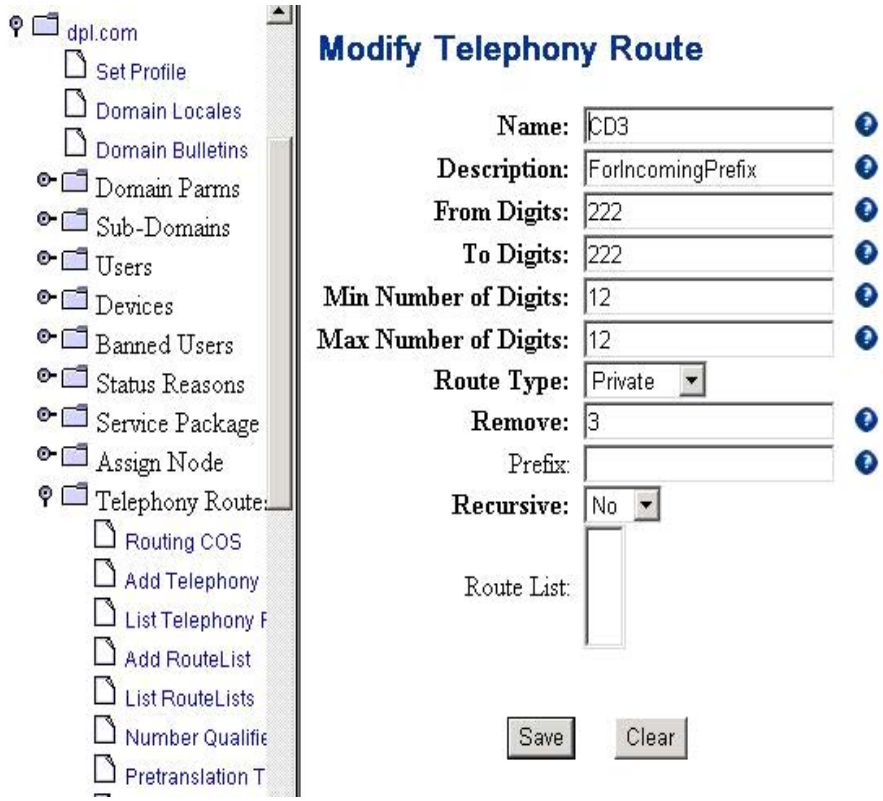
The following figure illustrates the call flow when the incoming requests have multiple CS2k profiles.

Figure 16 Incoming request with multiple CS2000 profiles



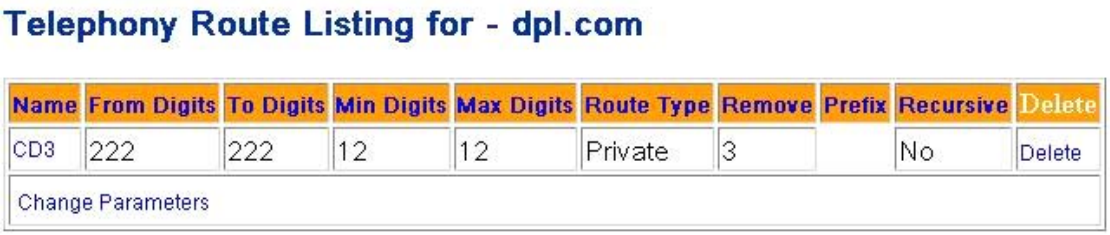
The administrator has to set up translations for each domain /sub-domain to strip the incoming prefix. For example, Figure 17 shows a route ‘CD3’ provisioned to remove the digits ‘222’.

Figure 17 Telephony route to strip CNi prefix



The following figure is the “List Telephony Routes” page from the provisioning client showing the route that was created to remove the incoming prefix (CNi).

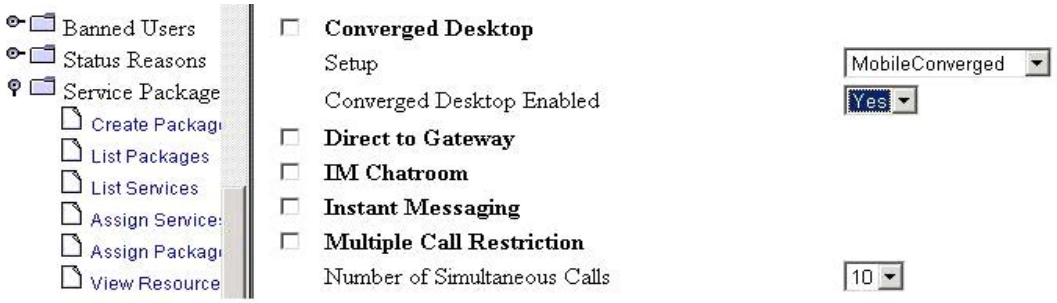
Figure 18 Listing of the telephony route



138.2.12.4 Service Package

A new option called “Mobile Converged” will be added to the Setup parameter of the Converged Desktop service. This option will be used to identify the users that will have this Mobile Converged service. In addition to that a new service called “Direct to Gateway” is introduced by this feature. This service defines if the calls have to be directed to a predefined gateway or not.

Figure 19 Provisioning the mobile converged desktop service



A new service called “Multiple Call Restriction” will be created. This service defines if the multiple call restriction should be enforced on the user or not. If enabled, the number of simultaneous calls that a user can have will be defined by the new parameter labeled “Maximum Number of Calls Allowed” that will be added to the “Multiple Calls Restriction” service. This will indicate the number of calls that the user can answer/hold. Min=1, Max=20, Default=10.

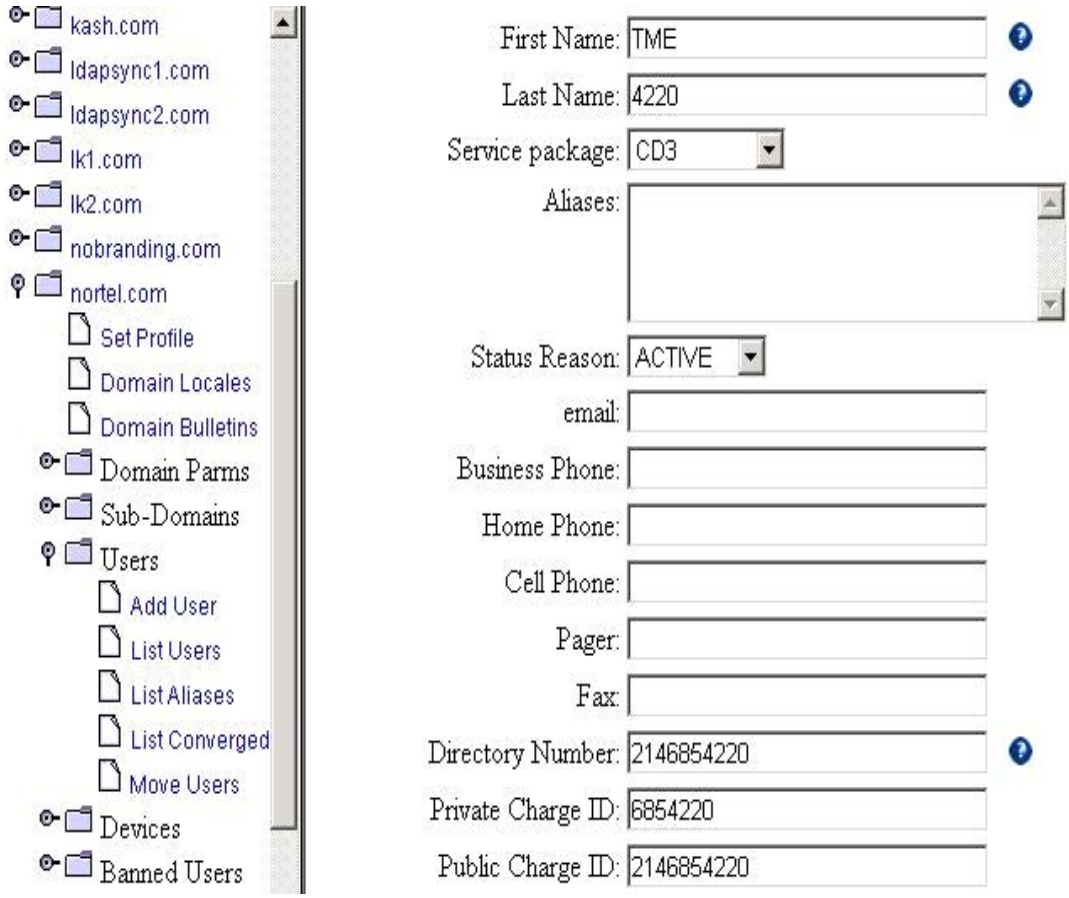
Figure 20 Provisioning Client screen shot for the new service parameter

Note: Refer to the Feature Interactions section for the list of supported and mutually exclusive services

138.2.12.5 Subscriber Provisioning

For users to be able to use this new service, the following information has to be provisioned. The user should be assigned to a service package that has the Converged Service which has the setup parameter of the service set to “Mobile Converged”.

The directory number (DN) field of the user is used to provision the user's MSISDN. The directory number of the user should be unique in the whole system. The directory number should be unique in the whole system. Provisioning rules will be in place which will make sure that the DN is unique in the whole system. Identifying a converged user without knowing the domain is necessary because converged calls that are routed from an existing switch to the MCP will always contain the same domain. This domain may or may not be the user's real domain. The following figure explains the page wherein the directory number can be provisioned for a user.



The audio device prefix (CRA) and the direct to gateway prefix (CRD) can optionally be provisioned at the user level to override the (sub) domain prefixes.

138.2.12.5.1 Audio Device Prefix

The audio device prefix can also be provisioned at the user level. This can be provisioned from the Converged Desktop Properties tab in the user details page. This will only be available to Mobile Converged users.

The following methods will be added to the existing ConvDesktopUserMgr OPI interface to be able provision this value from OPI.

```
/**
 * Adds the Prefix data for the mobile converged Service using the user as the key
 * @param String username, the user to which the service data belong.
 * @param String userPrefixData, the new service data
 * @throws ProvisionException: This exception is thrown when an input parameter is invalid,
 * a duplicate object exists in the data store, a dependency exists in the data store or the data
 * store is not available.
 */
public void assignUserMCPrefixData(String username, String userPrefixData) throws ProvisionException;

/**
 * Returns the user prefix data for the mobile converged Service using the username as the key
 * @param String username, the user to which the service data belong.
 * @param String userPrefixData, the user service data
 * @throws ProvisionException: This exception is thrown when an input parameter is invalid,
```

```
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
    * store is not available.
    */
```

public String getUserMCPrefixData(String username) throws ProvisionException;

```
     /**
    * This method is used for removing prefix data associated with a
user for the mobile converged service
    * @param String username, user from which the service data needs
to be removed.
   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
    * store is not available.
    */
```

public void removeUserMCPrefixData(String username) throws ProvisionException;

138.2.12.5.2 Direct to Gateway Prefix

The direct to gateway prefix can also be provisioned at the user level. This can be provisioned from the new “Prefix Data” tab in the user details page. This will only be available to Mobile Converged users who have the “Direct to Gateway” service.

A new interface called “UserPrefixDataMgr” will be created to have the methods required to provision this value from OPI.

```
/**
    * Adds the Prefix data for the user using the username as the key
    * @param String username, the user to which the data belongs.
    * @param String userPrefixData, the new prefix data
   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
    * store is not available.
    */
   public void assignUserDirectToGWPrefixData(String username, String
userPrefixData) throws ProvisionException;

   /**
    * Returns the prefix data for the user using the username as the key
   * @param String usernameD, the user to which the prefix data belongs
to.
    * @param String domPrefixData, the new service data
   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
    * store is not available.
    */
   public String getUserDirectToGWPrefixData(String username) throws
ProvisionException;
     /**
   * This method is used for removing prefix data associated with a user
    * @param String username, the user for which the data needs to be
removed.
   * @throws ProvisionException: This exception is thrown when an input
parameter is invalid,
    * a duplicate object exists in the data store, a dependency exists
in the data store or the data
```

```
    * store is not available.
    */
   public void removeUserDirectToGWPrefixData(String username) throws
ProvisionException;
```

138.2.12.6 Open Provisioning Interface (OPI)

The following summarizes the OPI methods that will be exposed as part of this feature.

These commands will also be available from the BPT command line tool.

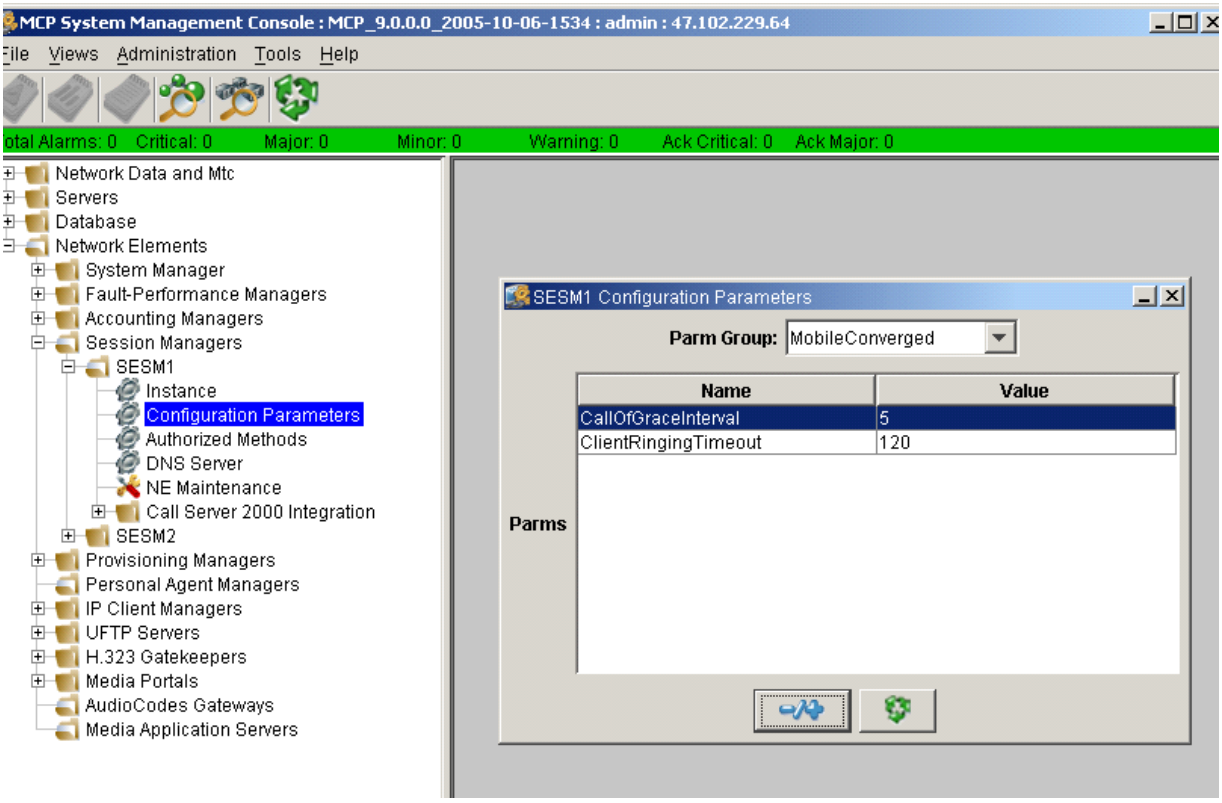
	Command	Parameter List
User Prefix	addMobileConvDesktopUserData	String username, MobileConvDesktopUserData userData
	getMobileConvDesktopUserData	String username
	removeMobileConvDesktopUserData	String username
Domain Prefix	addMobileConvDesktopDomainData	String domain, MobileConvDesktopDomainData domPrefixData
	getMobileConvDesktopDomainPrefixData	String domain
	removeMobileConvDesktopDomainPrefixData	String domain

138.2.12.7 System Configuration Parameters

Two new system parameters are available through the System Management Console GUI, the CallOfGraceInterval and ClientRingingTimeout. These parameters are both accessible through the System Management Console GUI and are provisioned for each Session Manager individually.

To access these parameters, click on the Configuration Parameters for a Session Manager and selecting the “Mobile Converged” Parm Group in the Configuration Parameters panel shown in the following figure.

Figure 21 Configuration Parameters Panel



138.2.12.7.1 CallOFGraceInterval

This parameter sets the call number interval the session manager will wait before attempting to present a subsequent call attempt to an MCD client after it has become “unavailable” as described in section “Client Unavailable / Calls of Grace” on page 1339.

138.2.12.7.2 RingingTimeout

This is a timer setting the number of seconds the session manager will allow an incoming call to a user currently registered on an MCD Client to remain ringing before bringing the call down. When this timer expires, a SIP BYE message is sent to the client to terminate the call leg to the MCD Client and a 480 Temporarily Unavailable sent to the originator to terminate the call and the call leg to the PAD is dropped.

138.3 Call Processing

This section details the call flow and supervision from the MCS network perspective.

138.3.1 Interfaces supported

The supported interface between the MCP and the existing switching system is Session Initiation Protocol (SIP).

138.3.2 Dial Plans

Two prefixes must be provisioned on the system for this feature. The CRD and CRA are defined again as follows:

- Destination Call Leg Return Code (CRD): This is an E.164 number that will prefix the (non CD) destination mobile number for outgoing calls from the MCD client to the mobile network.
- Associated Call Leg Return Code (CRA): This is an E.164 number that will prefix the CD mobile number (PAD). This prefix can be used to identify this call leg on the GSM network as a non-chargeable call.

The following sections discuss the usage of these prefixes for both terminating to a CD Mobile and originating from an MCD PC Client. Note that there is no section addressing conference calls since conference calls do not require establishing a new PSTN connection; thus, CDR and CDA prefixes are not required for joining the previously established calls into a conference.

138.3.2.1 Prefix usage for CD Mobile Terminations

The following table describes when the CRA is prefixed to a CD Mobile termination. The two scenarios considered are:

1. Call is received from another CD Mobile (row 1)
2. Call is received by non CD Mobile (row 2)

These rules also apply to ‘Advanced Routing’ (if provisioned) where the terminator has multiple destinations. For example, MSISDN-2 rings another CD mobile and then a non CD mobile. For both destinations the CRA needs to be added as described.

Figure 22 Prefix on CD Mobile Terminations

CD Mobile Terminations			
Originator	**Terminator**	**Called Number**	**Description**
CD Mobile (MSISDN-1) (CRA-1)	CD Mobile (MSISDN-2) (CRA-2)	CRA-2+MSISDN-2	CRA of the terminator is used in the called number here because the originator could be known, but not looked up at the MCS for CD Mobile to Mobile call.
Non - CD Mobile (MSISDN)	CD Mobile (MSISDN-2) (CRA-2)	CRA-2+MSISDN-2	CRA of the terminator is used here because the originator is unknown at the MCS.

138.3.2.2 Prefix usage for MCD PC Client Originations

The following table describes when the CRA and CRD are used when a client origination takes place to a

1. CD Mobile
2. Non CD Mobile
3. PSTN number

These rules also apply to ‘Advanced Routing’ (if provisioned) where the terminator has multiple destinations. For example, MSISDN-2 rings another CD mobile and then a non CD mobile. For both destinations the CRA/CRD needs to be added as described.

Figure 23 Prefix for Client Originations

MCD Client Origination / click-to-call				
Originator	**Terminator**	**CRA (Owner) First Leg (orig)**	**CRD (Owner) Second Leg (term)**	**Description**
CD Mobile (MSISDN-1) (CRA-1) (CRD-1)	CD Mobile (MSISDN-2) (CRA-2) (CRD-2)	CRA-1+MSISDN-1	CRD-1+MSISDN-2	CRA of the originator is used for the first and CRD of the originator is used in the terminating leg because it is a client origination.
CD Mobile (MSISDN-1) (CRA-1) (CRD-1)	CD Mobile (user ID) (MSISDN-2) (CRA-2) (CRD-2)	CRA-1+MSISDN-1	CRD-1+MSISDN-2	CRA of the originator is used for the first and CRD of the originator is used in the terminating leg because it is a client origination.
CD Mobile (MSISDN-1) (CRA-1) (CRD-1)	Non-CD Mobile (MSISDN)	CRA-1+MSISDN-1	CRD-1+MSISDN	CRA of the originator is used for the first and CRD of the originator is used in the terminating leg because it is a client origination.

138.3.2.3 Prefix Usage for Call Transfer

The following table describes when the CRA and CRD are used when a client transfers a call. The table below has a call setup between party A and B, then party B transfers the call to party C.

The rules need to also apply to ‘Advance Routing’ where the terminator has multiple destinations. For example, MSISDN-3 rings another CD mobile and

then a non CD mobile. For both destinations the CRD needs to be added as described. The same rules will apply if Party B forwards the request to Party C.

Figure 24 Prefix used for call transfer

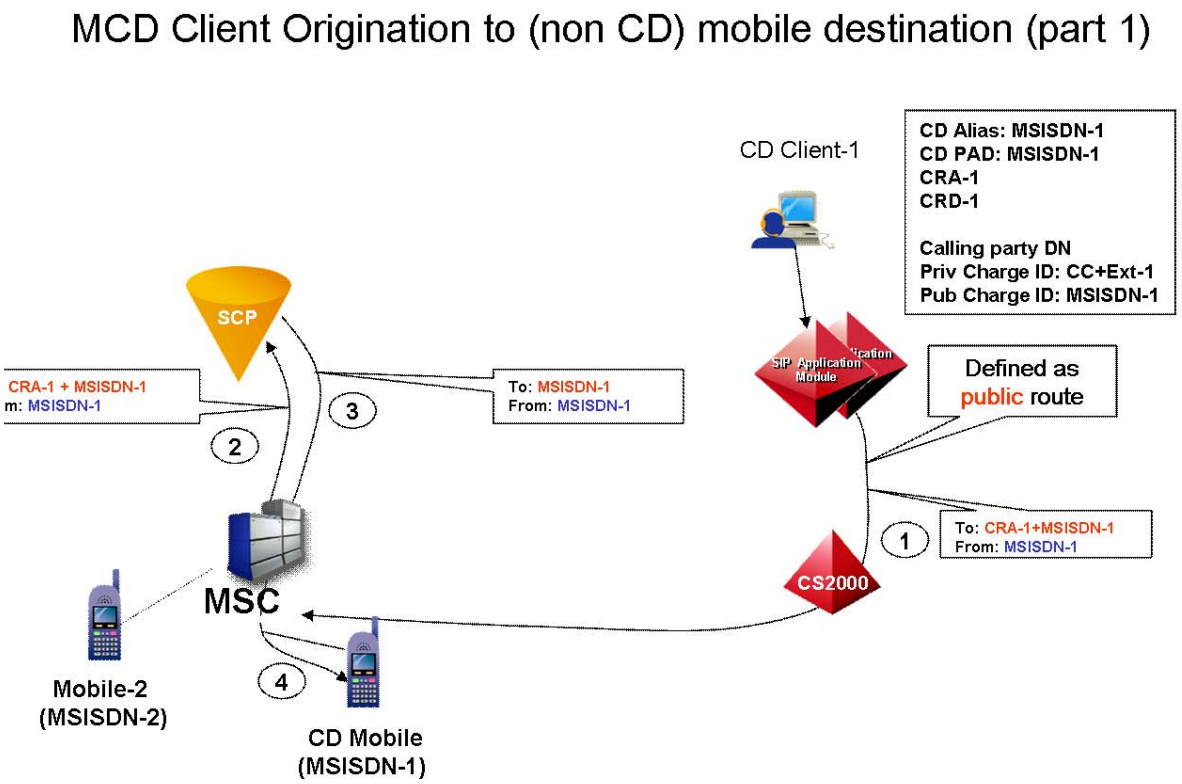
Call transfer					
Party A	**Party B (transferring party)**	**Party C (transfer party)**	**Calling Number sent to Party C**	**Called Number sent to Party C**	**Description**
CD Mobile (MSISDN-1) (CRA-1) (CRD-1)	CD Mobile (MSISDN-2) (CRA-2) (CRD-2)	CD Mobile (MSISDN-3) (CRA-3) (CRD-3)	(TBD)	CRD-2+MSISDN-3	CRD of the transferring party is used because party C is a known MCS user. This is similar to party B just originating a call to party C.
CD Mobile (MSISDN-1) (CRA-1) (CRD-1)	CD Mobile (user ID) (MSISDN-2) (CRA-2) (CRD-2)	Non-CD Mobile (MSISDN)	(TBD)	CRD-2+MSISDN	CRD of the transferring party is used because party C is a known MCS user. This is similar to party B just originating a call to party C.

138.3.3 MCD PC Client Originated Scenarios

The situation in which a converged user (MCD Client-1) makes a call to a mobile user (Mobile-2) from the MCD PC Client is discussed. Since the MCD PC Client does not provide the audio for the call, all originations from the PC client are click-to-call scenarios.

The Click-to-call scenario always involves two call legs. The first call is to the CD Mobile (MSISDN-1), and is illustrated in Figure 25.

Figure 25 Call origination from MCD PC Client (part 1)



Step 1: MCS Application Server attempts to establish the audio call with the MSISDN-1 by first prefixing with the originators CRA and routing to the CS2000. The CS2000 translates and sends ISUP IAM to the MSC of the mobile network.

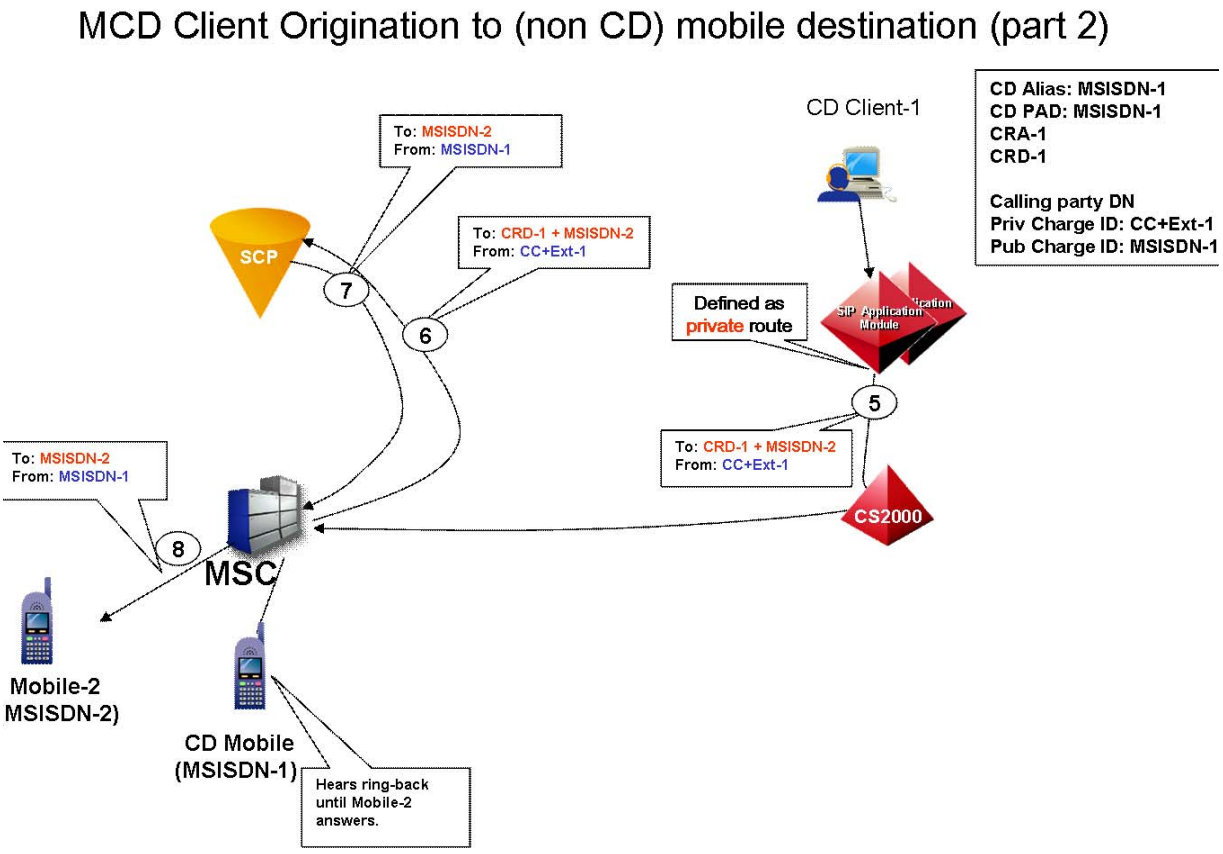
Step 2: The CRA+MSISDN-1 is presented to SCP for the originating leg.

Step 3: SCP removes CRA and sends the call to the CD Mobile (MSISDN-1). Note that the request is not sent back to MCS.

Step 4: The originator's mobile rings and originator answers the call.

The second half of the call attempts to establish the audio call with the non CD terminating Mobile-2. This scenario is illustrated below in Figure 26.

Figure 26 Call origination from MCD PC Client (part 2)



Step 5: The MCS application server sets up a call leg to the terminating mobile by prefixing the CRD of the originator to the terminators address (MSISDN-2). The ‘From’ is changed to the CC+Ext-1 of the originator.

Step 6: The MSC send the request to the SCP.

Step 7: SCP modifies the called and calling party to the actual MSISDN involved

Step 8: Request to MSC is sent to ring the terminating mobile.

The MCS Session Manager click-to-call call flow is slightly more complicated than described in the proceeding overview. The call flow from the perspective of the MCS Session Manager is shown in Figure 27. Most SIP signaling must go through the CS2000, thus the SESM executes internal REFER logic using Hold/Retrieve. Relevant aspects of the hold/retrieve are highlighted in the call flow.

Figure 27 MCD PC Client origination with ringback from far end

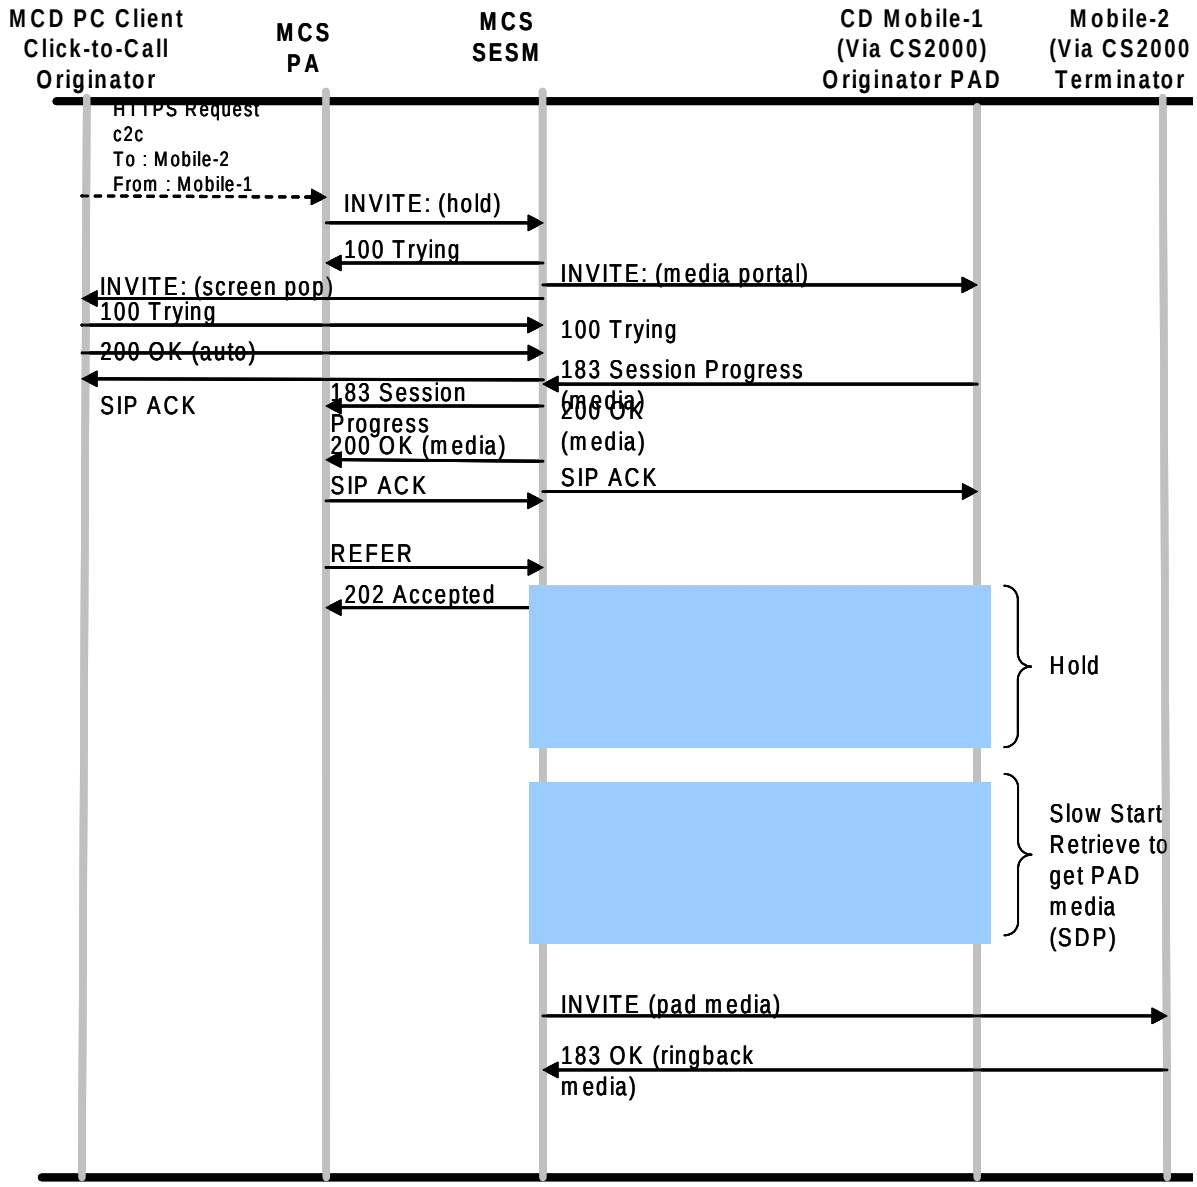


Figure 28 MCD PC Client origination with ringback from far end (cont.)

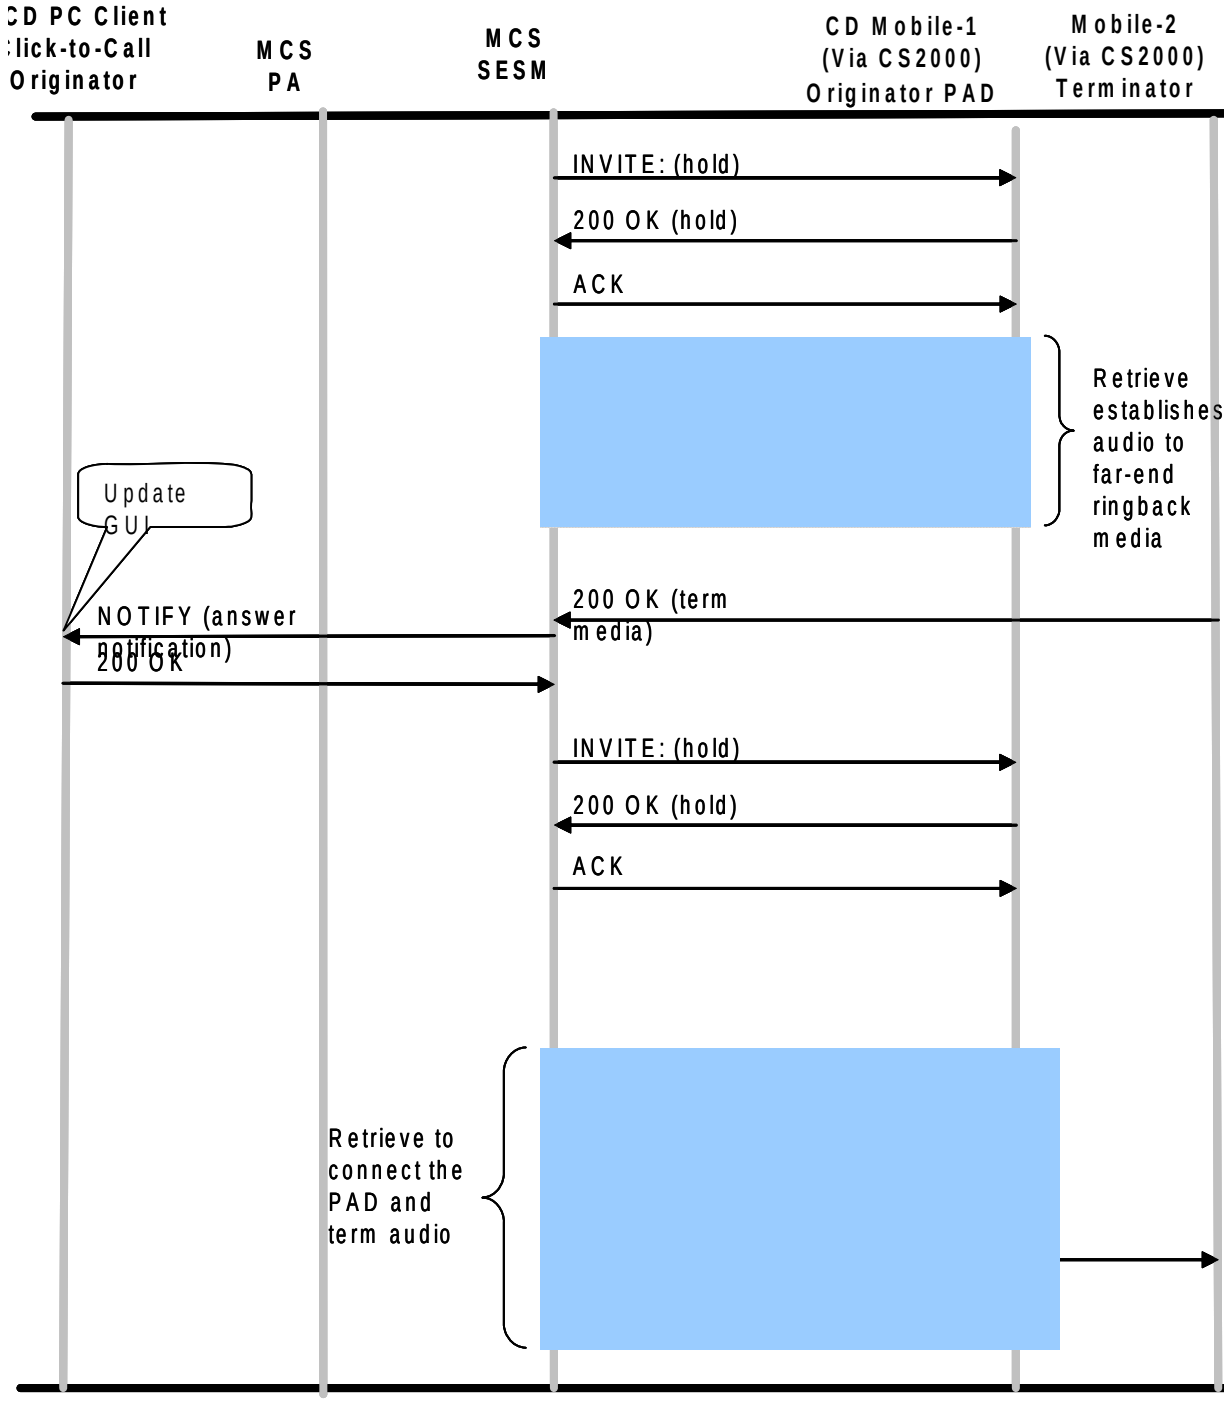


138.3.4 PAD Terminated Scenarios

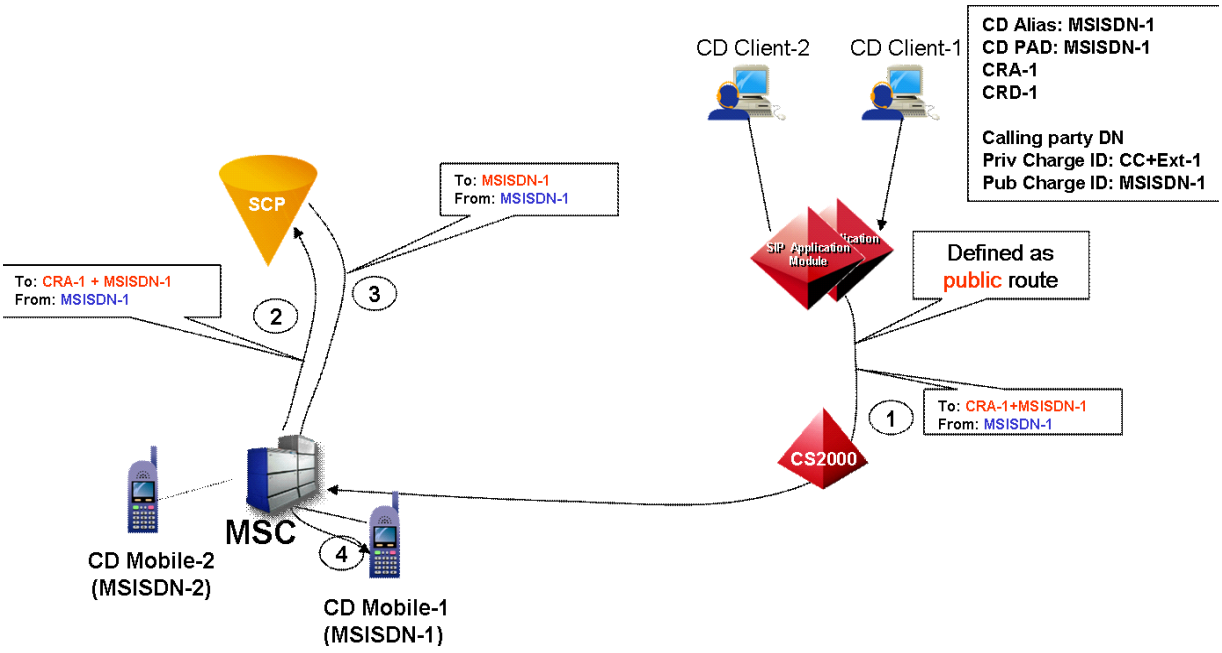
This section covers the termination scenario in which a converged subscriber (CD mobile-1) makes a call to a CD User (CD mobile-2). It also deals with

situations in which the inbound call is Ignored and Rejected from the MCD PC Client.

138.3.4.1 Call Answer on PAD

The basic termination to the converged users PAD is shown in Figure 28. In this scenario a converged wireless subscriber (CD Mobile-1) calls another converged wireless subscriber (CD Mobile-2).

Figure 29 CD call termination (part 1)



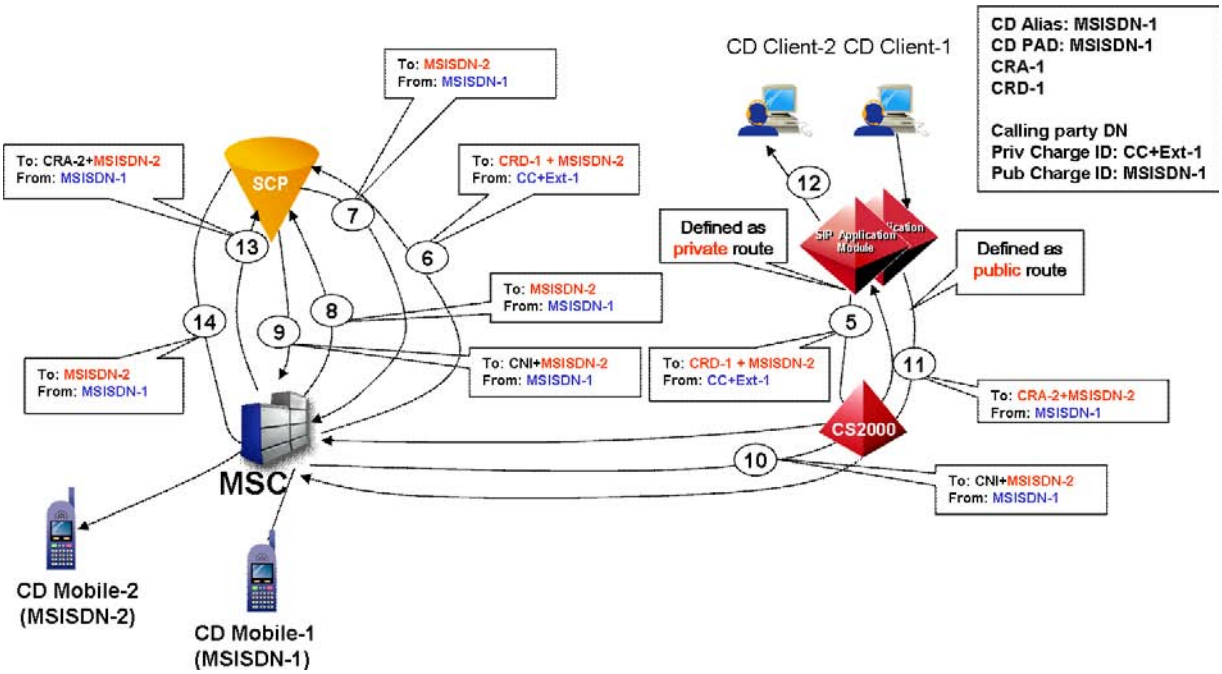
Step 1: First leg terminates to the CD mobile's own mobile device. Owner's CRA+MSISDN is the called and MSISIDN-1 is the calling party. CRA routing needs to use a public telephony route so public charge ID (MSISDN-1) is presented as the calling number.

Step 2: CRA+MSISDN-1 is presented to SCP for the originating leg

Step 3: SCP removes CRA and sends the call to the Mobile-1 which answers the call.

Step 4: The originator's mobile rings and the originator answers the call.

Figure 30 Call Termination (part 2)



Step 5: CRD of the originator is prefixed to the terminator's MSISDN and from party is changed to CC+Ext of the originator.

Step 6: The MSC sends the request to SCP.

Step 7: SCP modifies the called and calling party to the actual MSISDN involved.

Step 8: The MCS sends the request to the SCP again to add the CNI.

Step9: SCP prefixes the CNI to the terminating call

Step 10: Request received at the MCS with CNI (or without if CS2k removes it).

Step 11: MCS adds the CRA of the terminating party and routes the request to the MSC

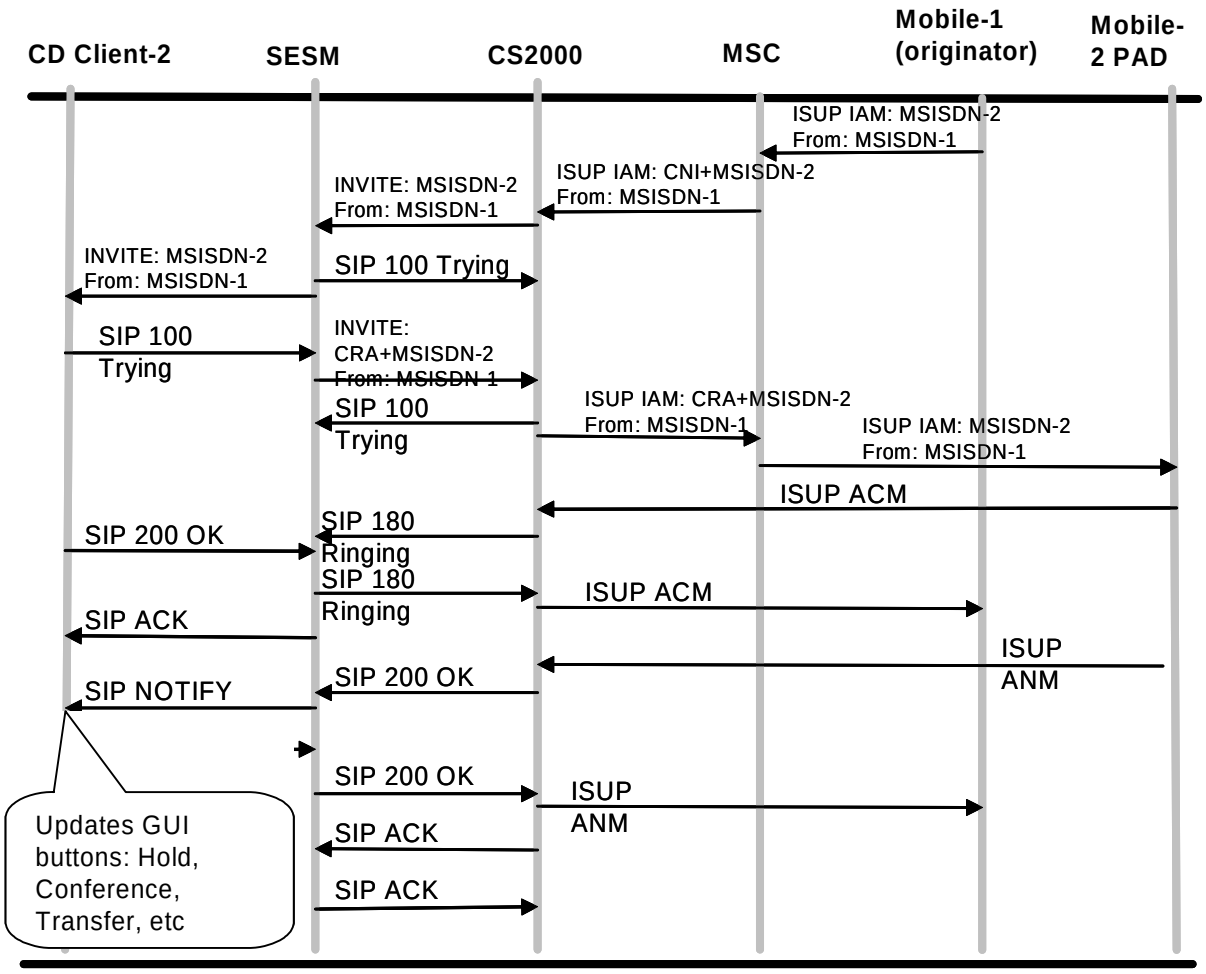
Step 12: CD Client-2 is presented with call.

Step 13: MSC sends the request to the SCP to remove the CRA.

Step 14: Request to MSC is sent to ring the terminating mobile.

The call flow from the perspective of the MCS Session Manager is shown below.

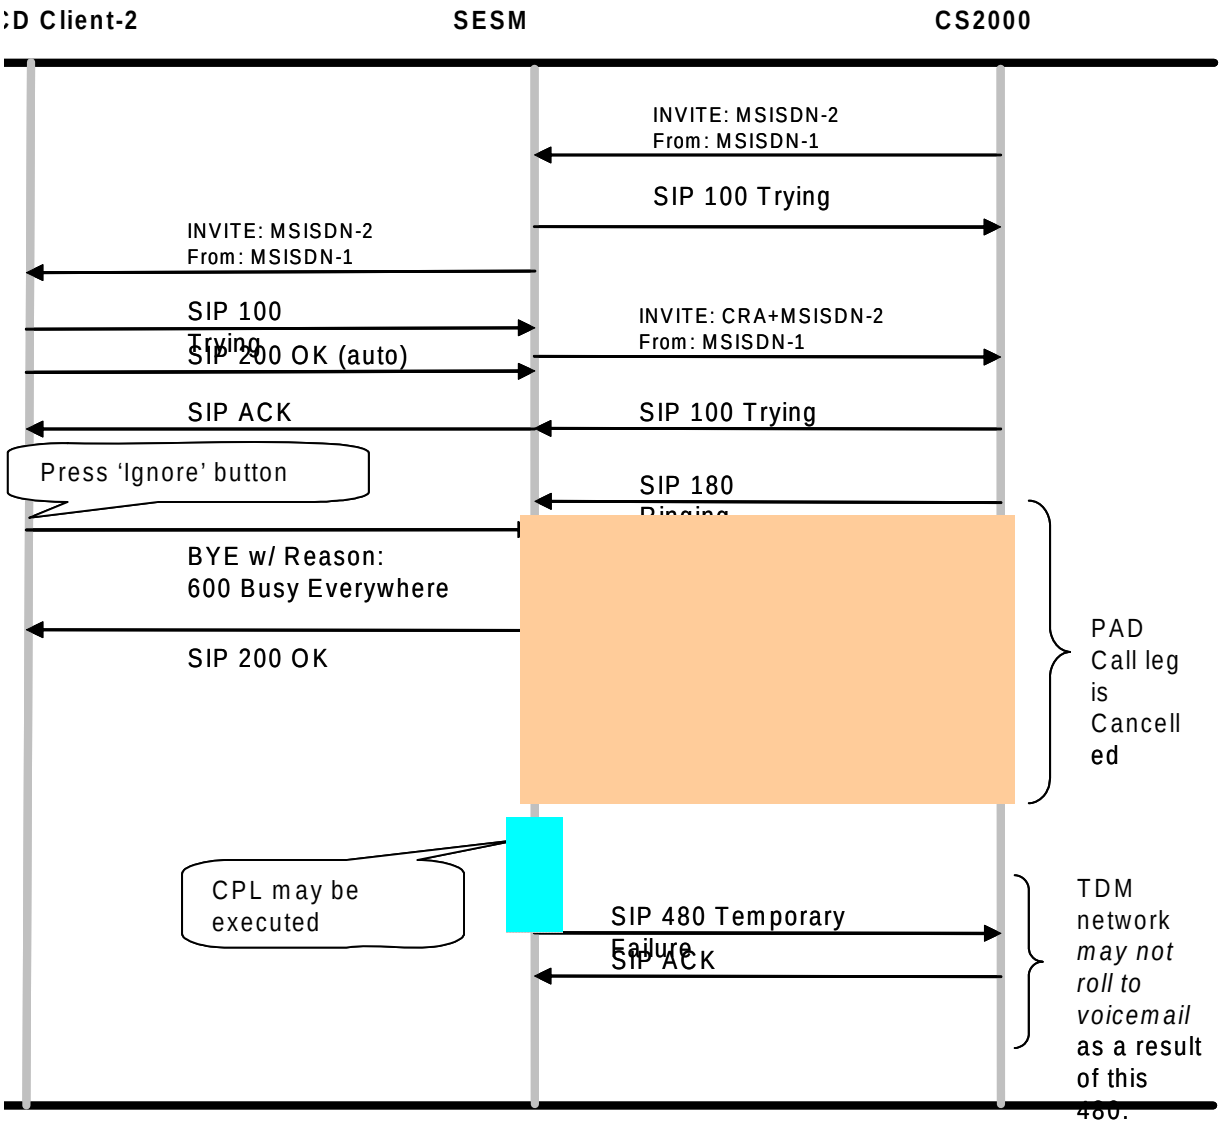
Figure 31 MCD PC Client termination



20.3.4.2 Call Ignore from MCD PC Client

Incoming calls to the MCD PC Client call be ignored. This will allow the SESM to execute any MCS CPL scripts (advanced routing) and/or roll to MCS voicemail. The call flow from the perspective of the MCS Session Manager is shown below.

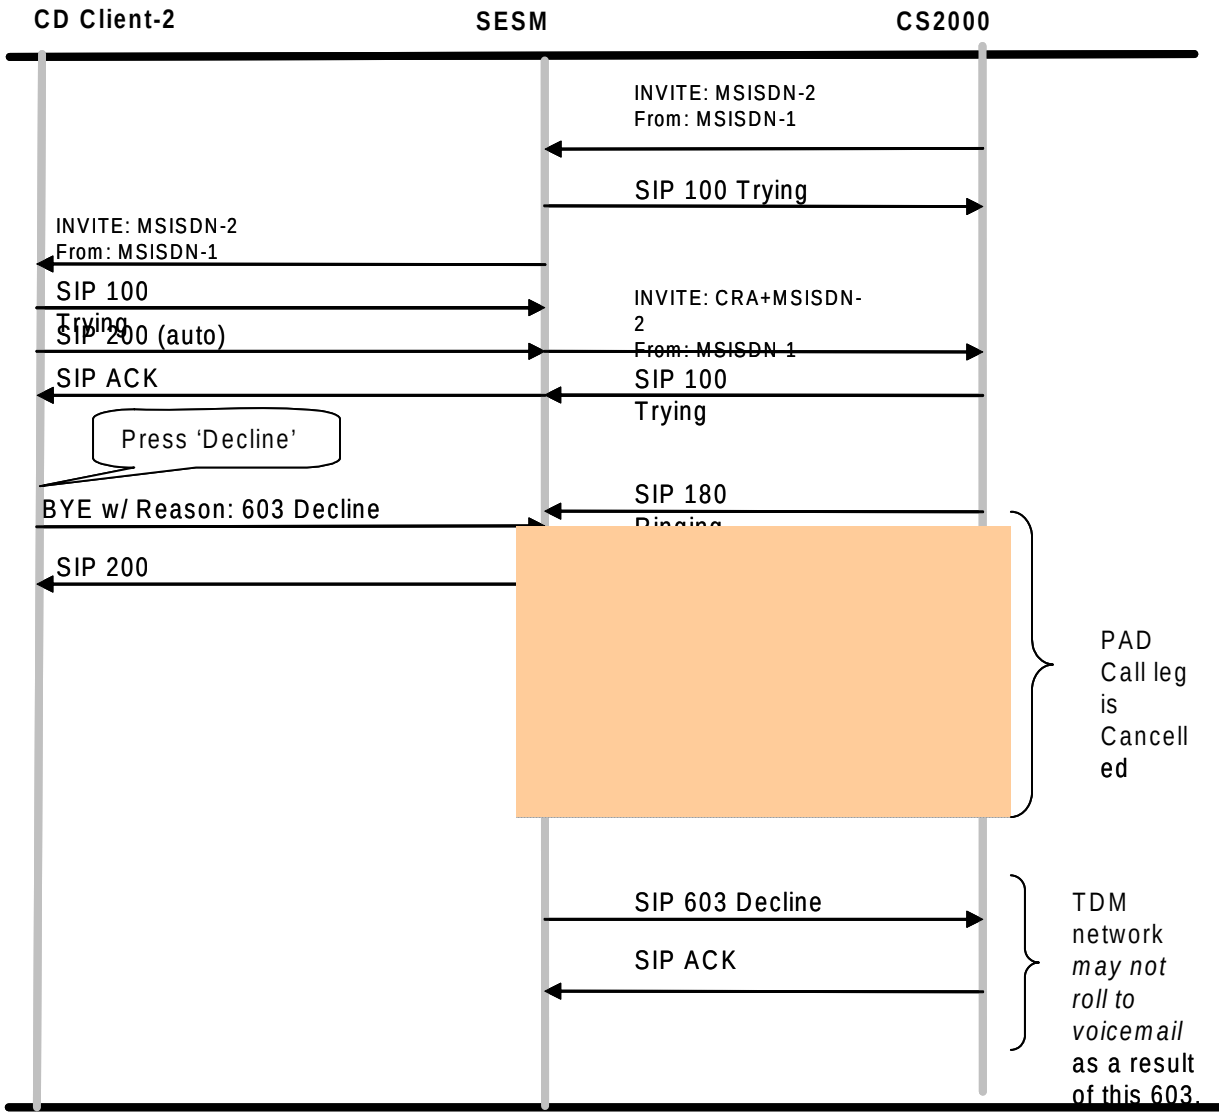
Figure 32 MCD PC Client Ignores inbound call (no CPL)



20.3.4.3 Call Decline (reject) from MCD PC Client

Incoming calls to the MCD PC Client call be rejected. The call flow from the perspective of the MCS Session Manager is shown below.

Figure 33 MCD PC Client Declines inbound call



20.3.5 Established Call Behavior

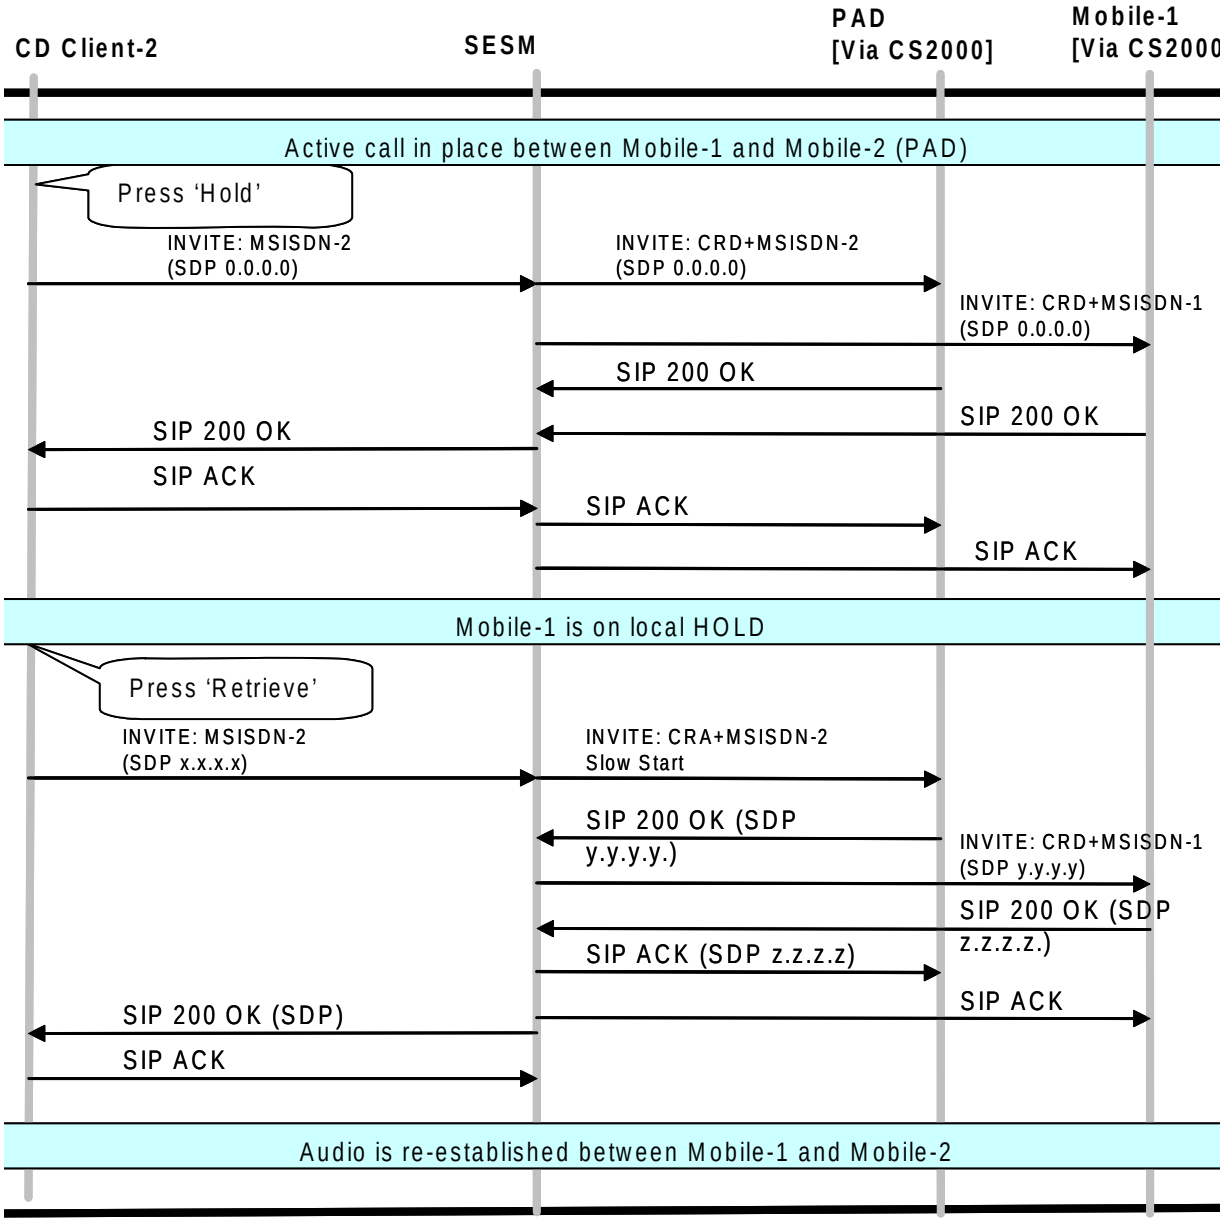
This section covers the situations in which a converged subscriber (mobile-1) already has an established call and additional mid-call features are being requested from the terminating MCD PC Client. Specifically, the scenarios presented are Hold / Retrieve, Conference, and Direct Transfer from the MCD PC Client.

20.3.5.1 Hold/Retrieve from MCD PC Client

The PC Client allows active calls to be placed on local hold by pressing the Hold button. This behavior is also invoked automatically if the client answers subsequent incoming calls. The call flow for the PC Client invoking local hold

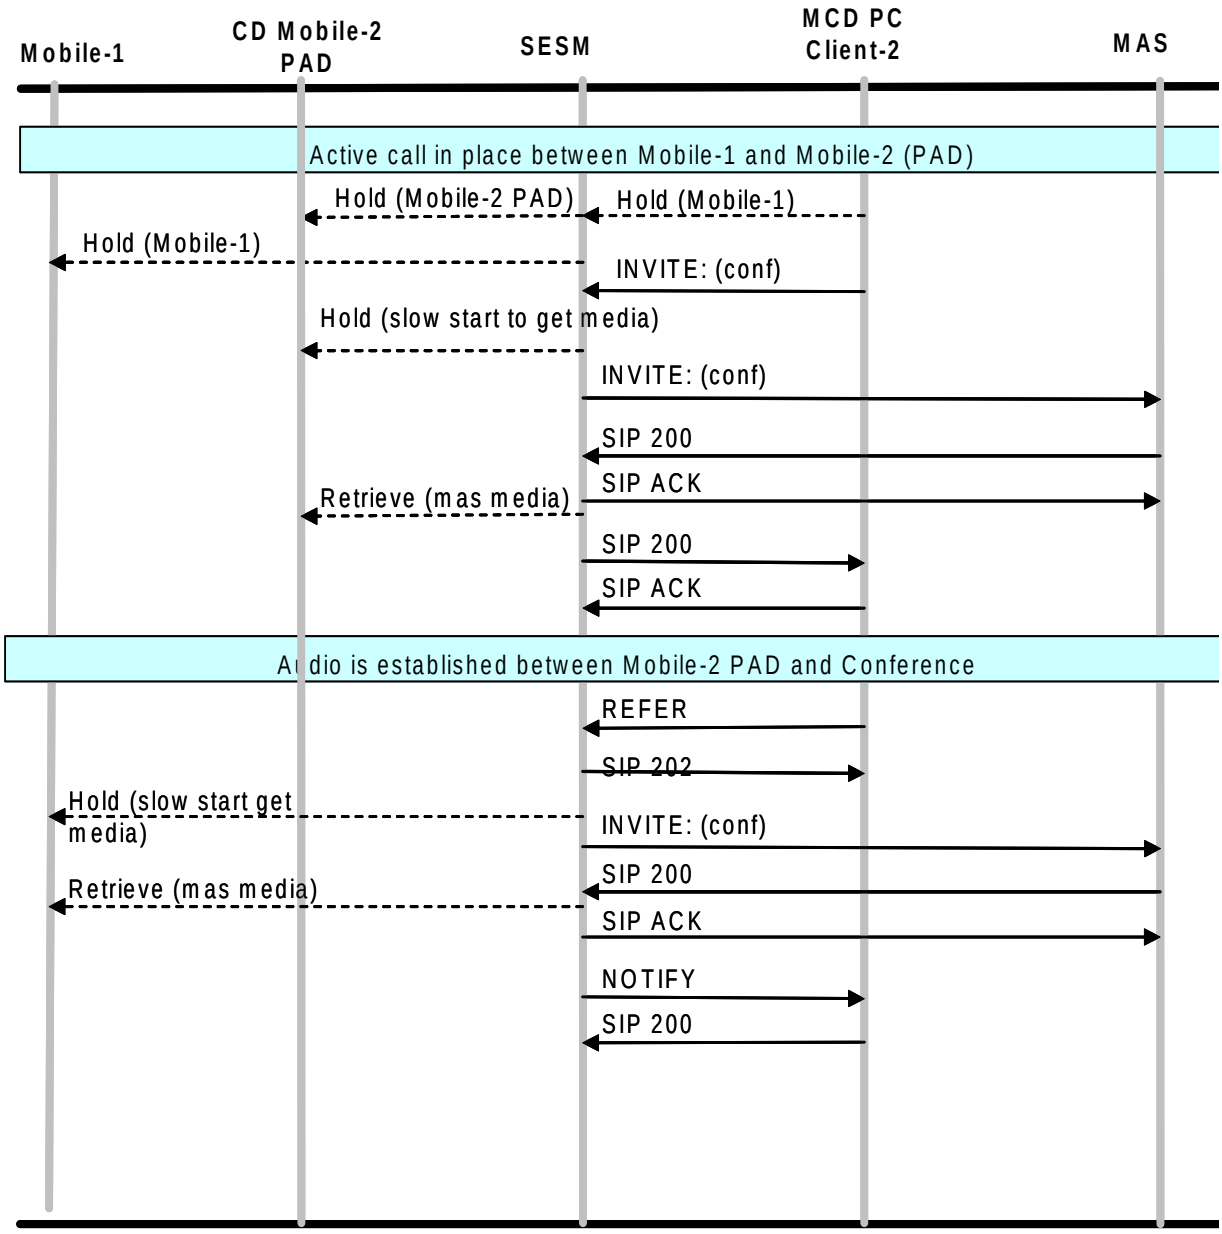
is as follows. (Note that call flows for hold and retrieve may be abbreviated in subsequent sections for simplicity.)

Figure 34 MCD PC Client Hold/Retrieve call



20.3.5.2 Conference from MCD PC Client

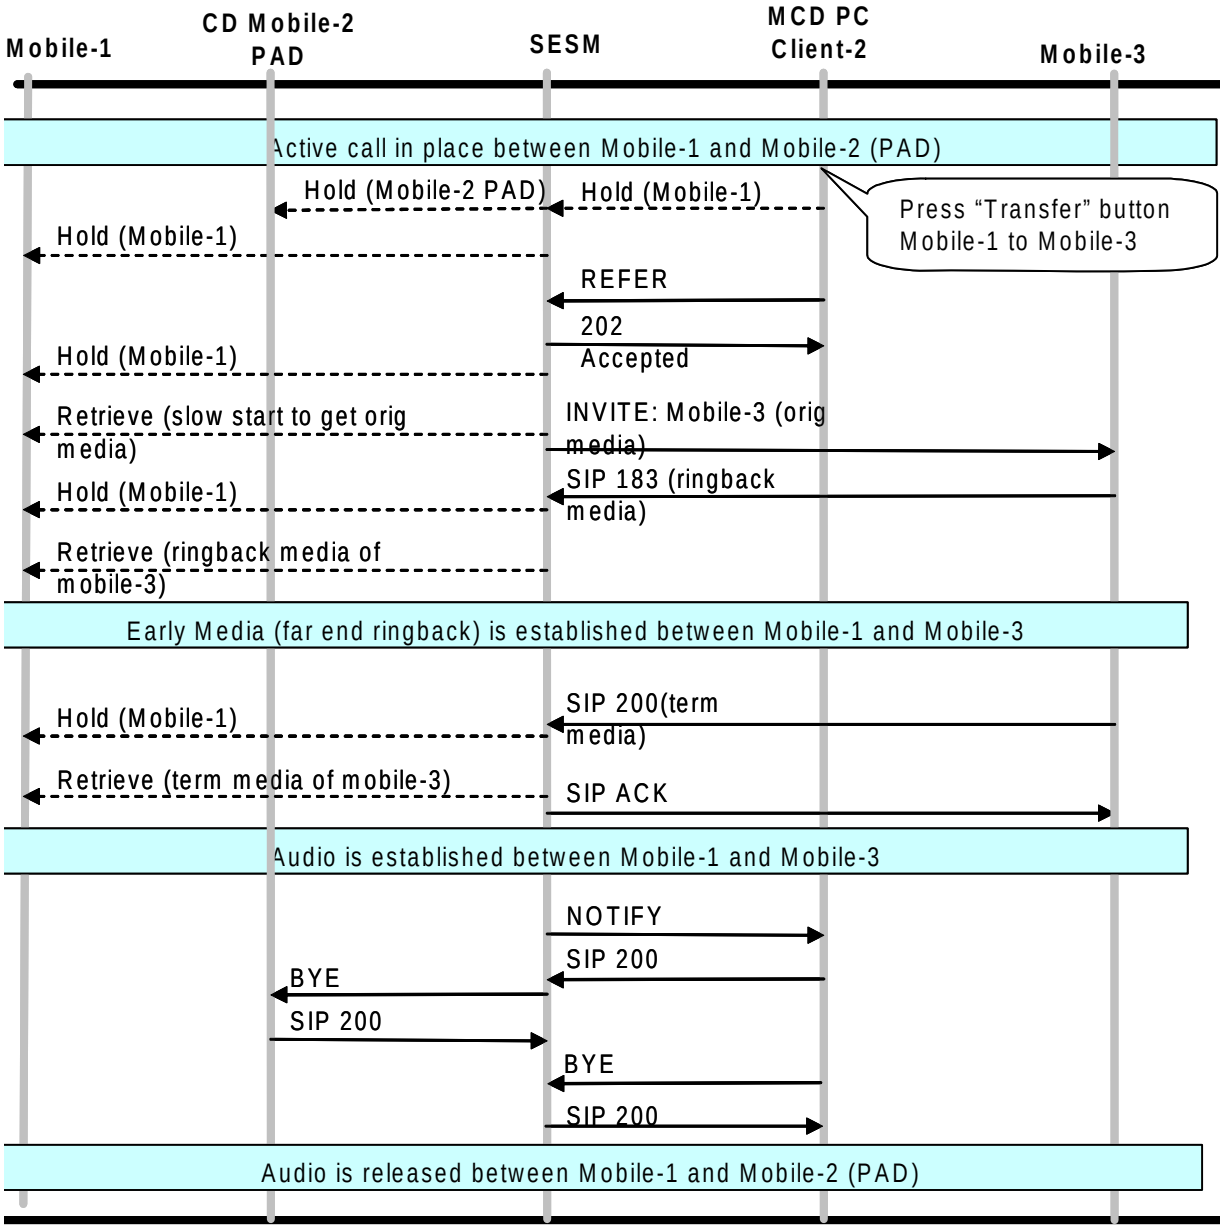
The call flow for the PC Client joining users into a conference is as follows.



20.3.5.3 Transfer from MCD PC Client

An established call exists between Mobile-1 and CD Mobile-2 (PAD). The MCD PC Client-2 invokes a direct transfer of this established call to Mobile-3. An abbreviated call flow for the direct transfer to is shown in Figure 35. Only Mobile-2 is a converged user. Most SIP signaling must go through the CS2000, thus the SESM executes internal REFER logic using Hold/Retrieve.

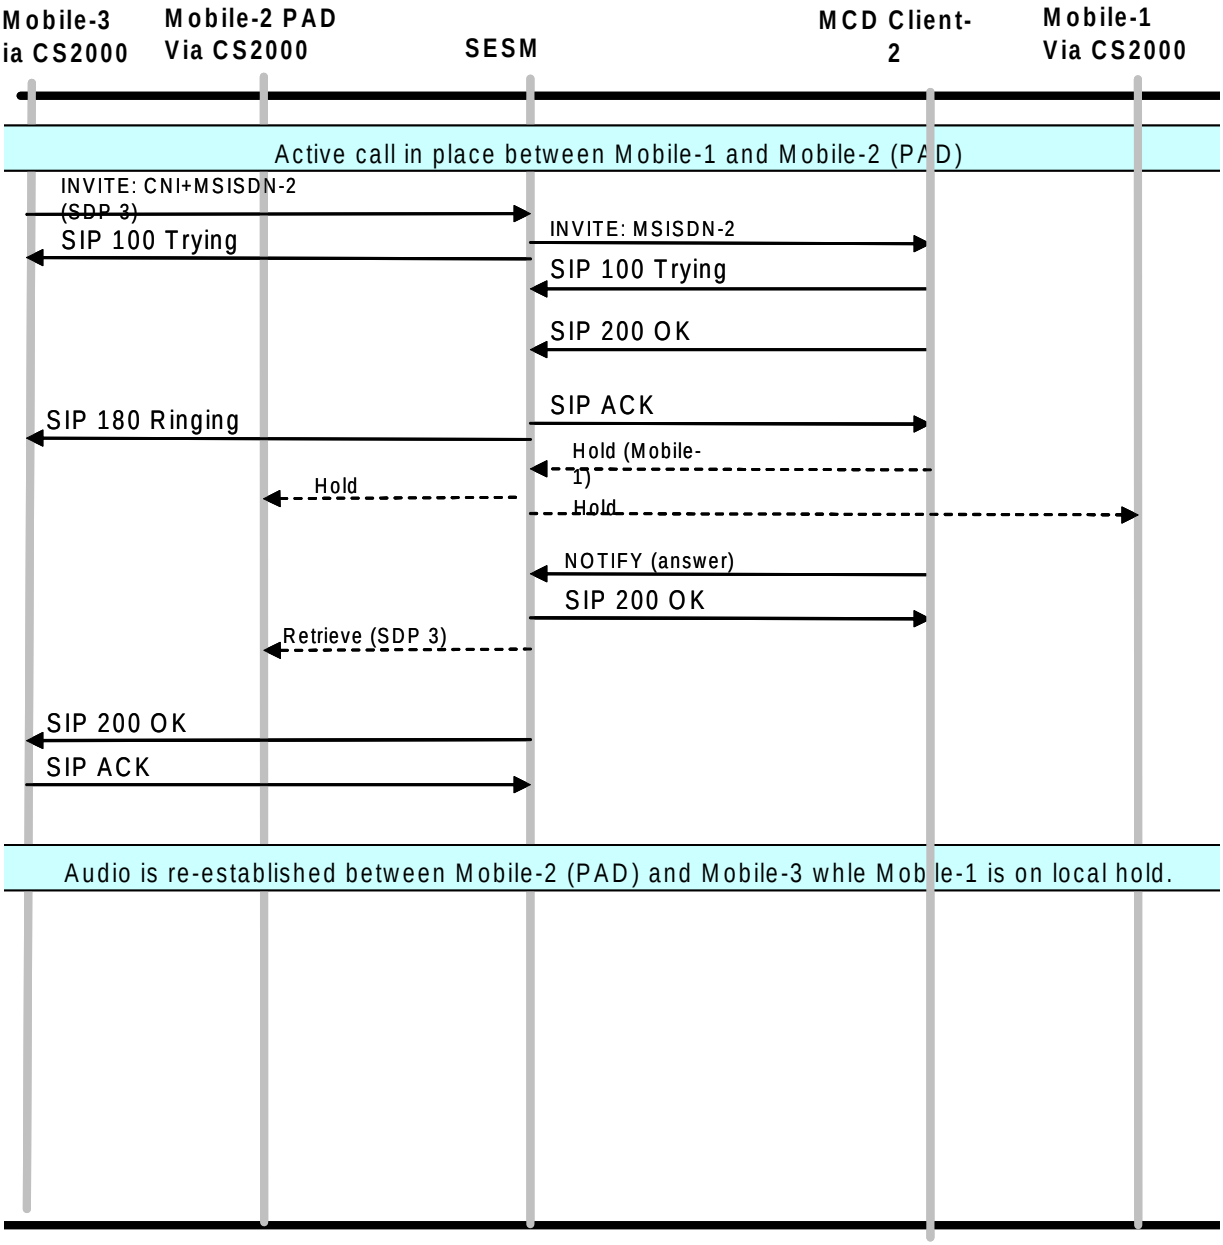
Figure 35 MCD PC Client Transfers call



20.3.5.4 New Inbound Call to PAD (multi-call)

The call flow for the PC Client new call is as follows.

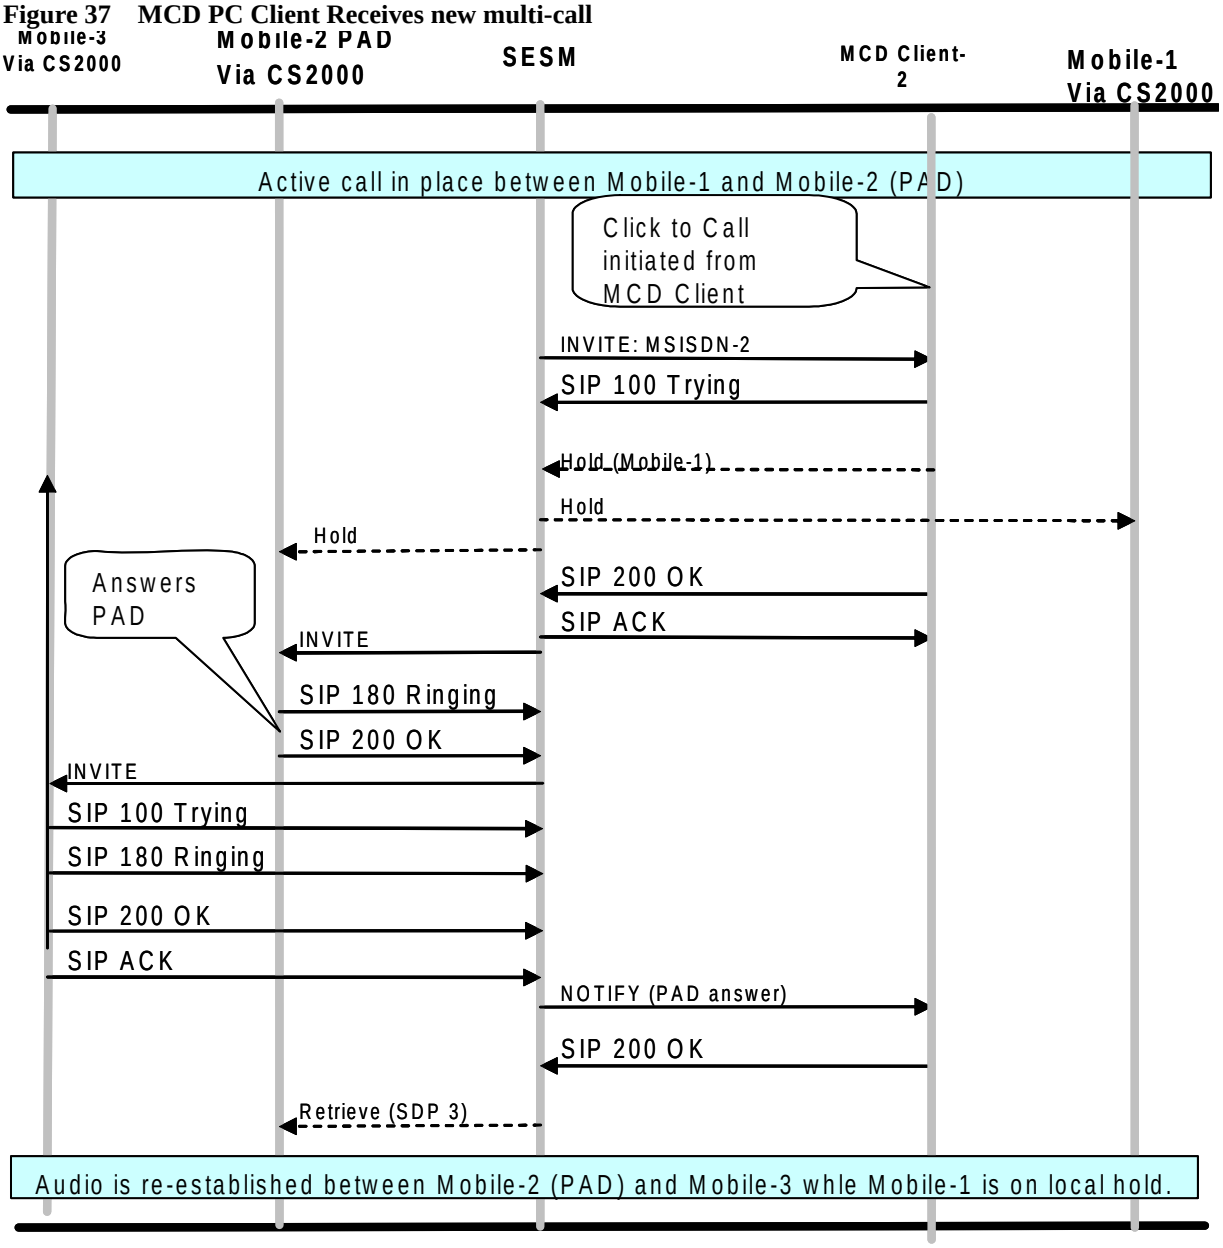
Figure 36 MCD PC Client Receives new multi-call



20.3.5.5 New Outbound Call to PAD (multi-call)

The call flow for the PC Client new call is as follows.

Figure 37 MCD PC Client Receives new multi-call



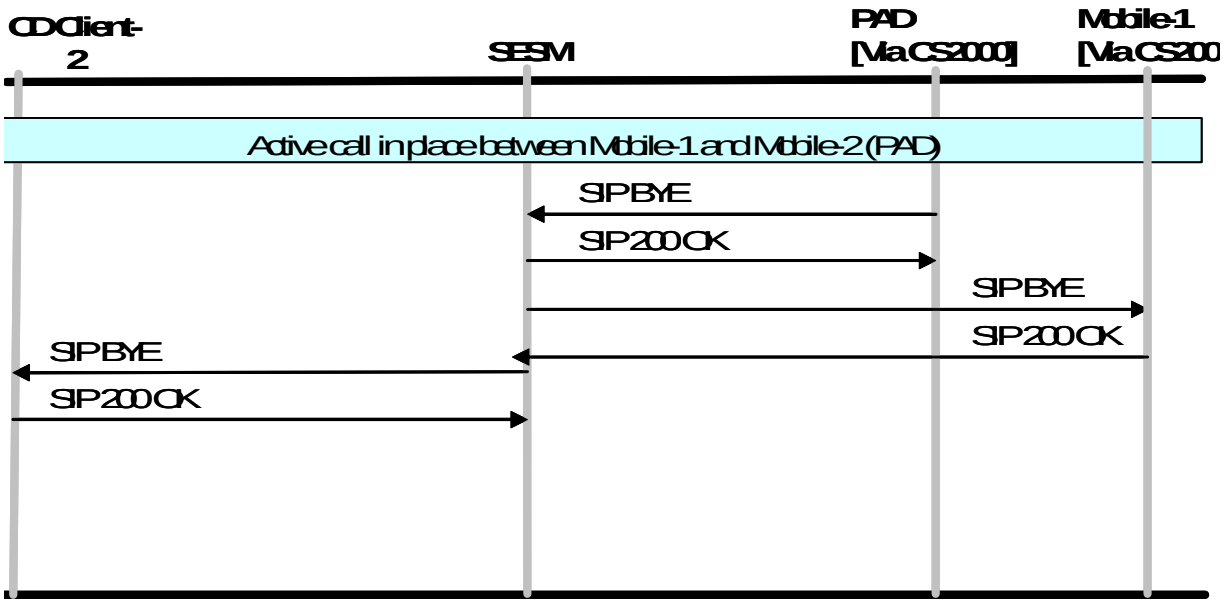
20.3.6 Release Scenarios

This section covers the situations in which a subscriber (mobile-1) disconnects established calls. Specifically, the scenarios presented are PAD Release, Network Release and Release from the MCD PC Client

20.3.6.1 PAD Release

The PAD release and the TDM network release appear identical from the MCS perspective. The call flow is shown below.

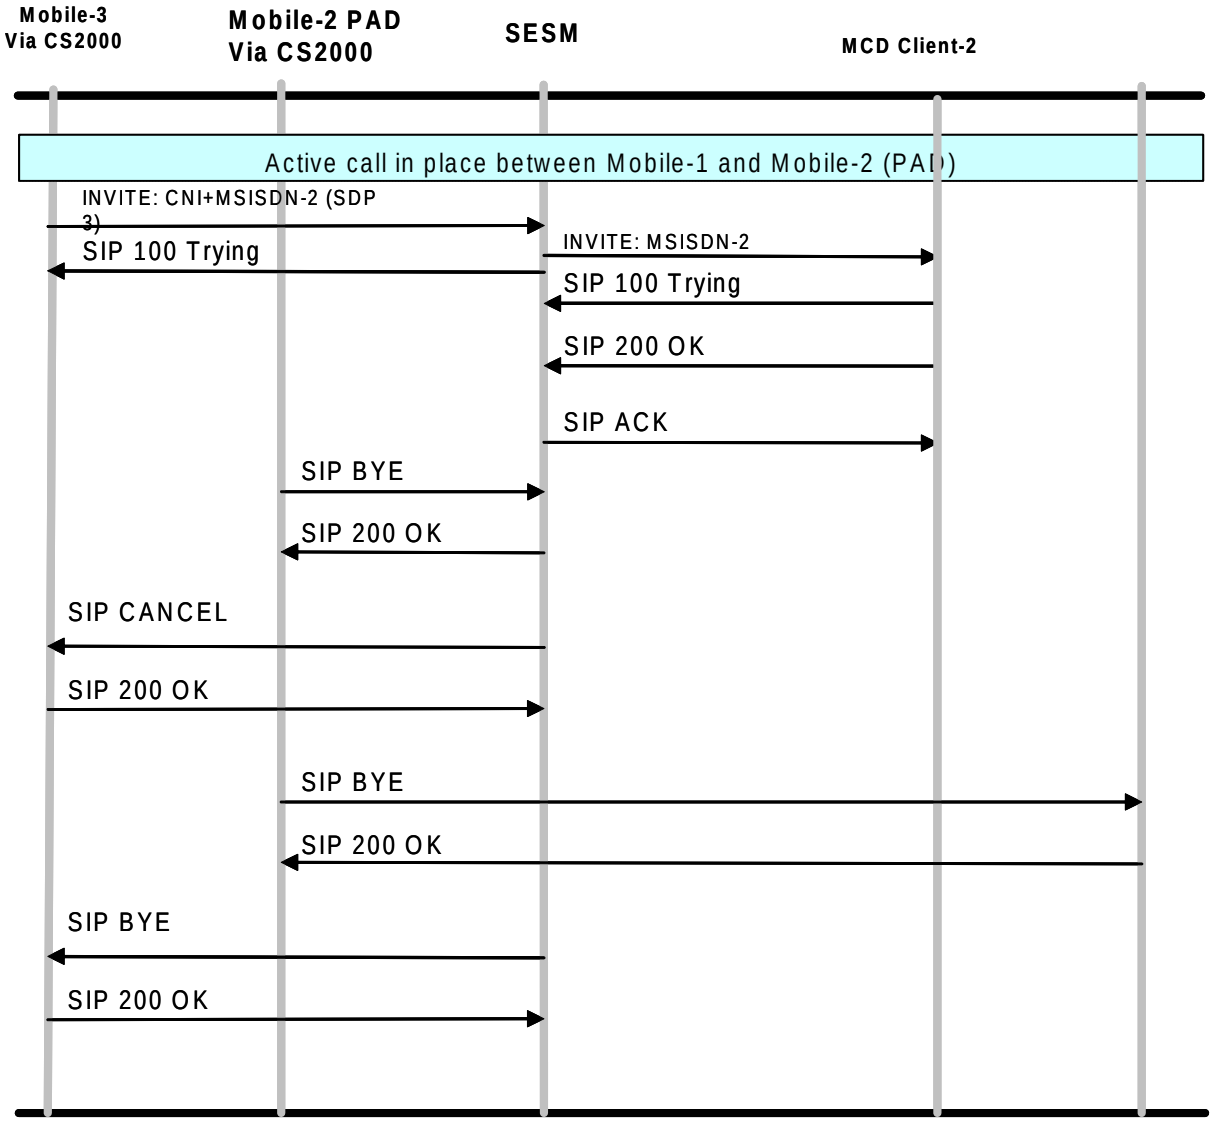
Figure 38 PAD Release



20.3.6.2 PAD Release for Inbound Call (multi-call)

The call flow for the PC Client new call is as follows.

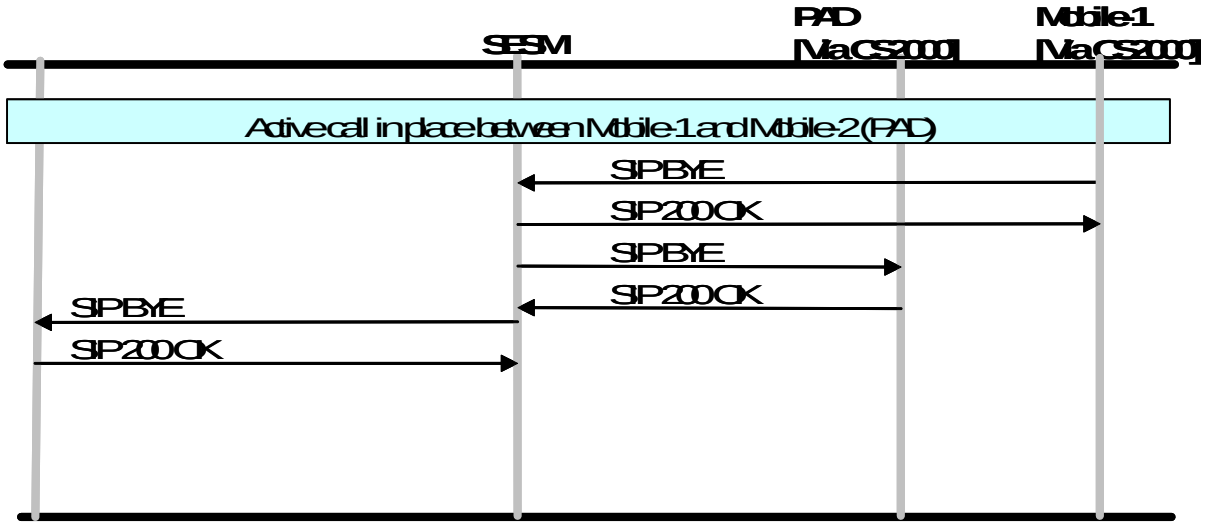
Figure 39 PAD Release for Inbound Call (multi-call)



20.3.6.3 Remote Party Release

The call flow for the PC Client new call is as follows.

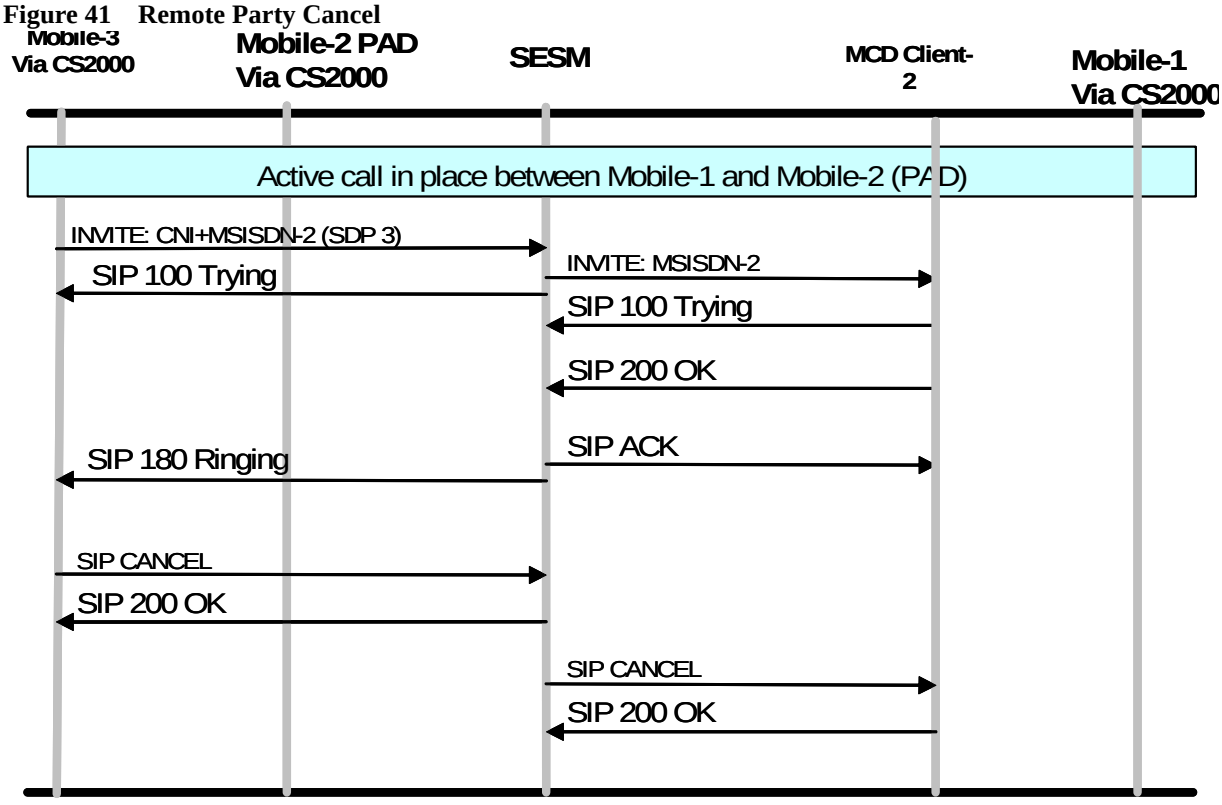
Figure 40 Remote Party Release



20.3.6.4 Remote Party Cancel

The call flow for the PC Client new call is as follows.

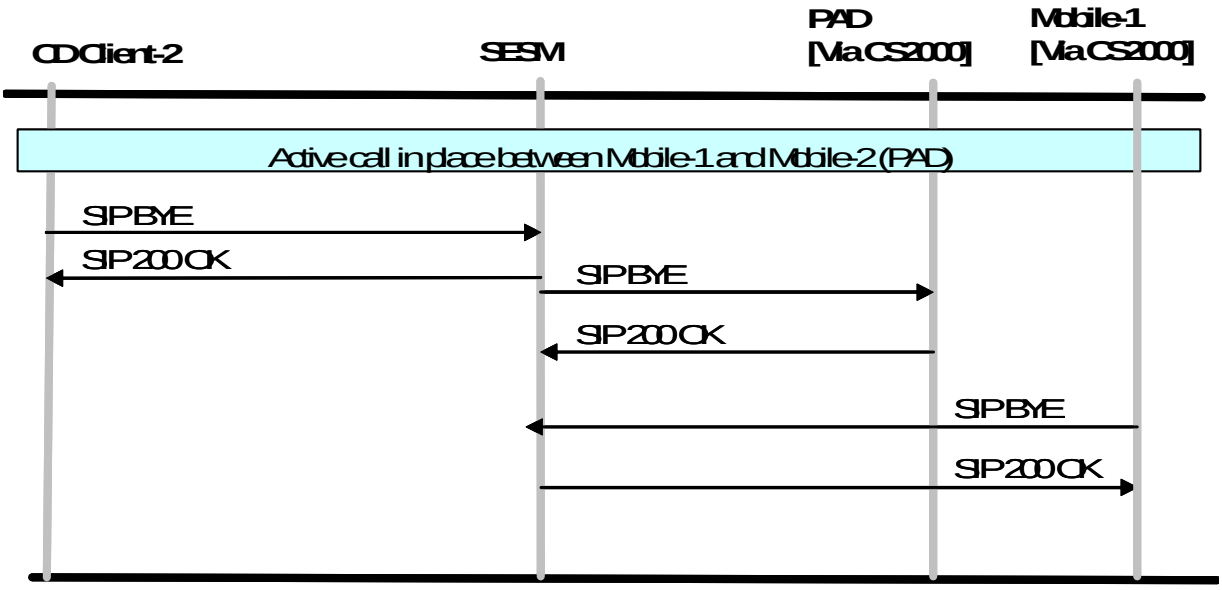
Figure 41 Remote Party Cancel



20.3.6.5 MCD PC Client Release

The PC Client release can occur for any active call leg. The call flow below illustrates the scenario where the establish call is released from the PC Client.

Figure 42 PAD Release



20.4 Hardware Requirements or Dependencies

The Nortel Communication Server 2000 (CS2000) is required to perform the features described.

20.5 Software Requirements or Dependencies

The following software is required to perform this feature.

MCS Component	MCS External Dependency	Description
Sip Application Module	Nortel CS2K or DMS Release ISN08 (or later)	The Wireless Converged Desktop service provides multimedia functionality to existing Mobile TDM switching systems. This entry lists the switch releases that the service supports.

20.6 Limitations and Restrictions

The following restrictions apply to this feature:

1. Video Calls are not supported in this release.

2. Functionality initiated by the PAD does not interact with the MCD feature, and call stated reflecting such services functionality will not be reflected by the MCD PC Client. For example, if a call is put on hold via the PAD, it will not appear to be put on hold as observed on the MCD PC Client, or a call originated by the PAD will have no call control window presented by the MCD PC Client.
3. Dual Hold is not supported on the MCD PC Client in this release. This scenario is when the client attempts to put a call on hold when the call has already been placed on hold by the far end. When the MCD Client has been put on hold (remote hold) and the hold button is blinking to indicate the call is on hold, clicking the hold button will have no effect and will not cause the client to attempt to hold the call again from the client's near end (local hold). Note that this restriction is only applicable when the far end is a SIP or MCD Client user; thus, if the far end is a mobile user and holds the call, as described in restriction 2, the MCD PC Client nor the MCD Service running on the Application Server will be unaware the call is on hold and will not prevent this dual hold scenario.
4. On-call-presence is not supported for PAD originations in this release.
5. The Converged Multimedia PC Client presence works only when the client is registered. If the user logs out of the MCD PC Client, or disconnects from the network, presence will not be correct until the PC Client re-registers.
6. Call Logs (including network call logs) will not be generated for PAD originations.
7. Call logs for MCD PC Client terminated calls contain the CLI provided by the CS2K. Prefixes may be required for call log originations to complete.
8. Call redirection (before answer) is not available in this release.
9. Consult transfer of established calls is not available in this release.
10. Call Park is not available on the Converged Multimedia Client.
11. CS2K overflow routing must be considered and engineered as part of the provisioning of this feature. This is because an MCS SESM outage can impact TDM call completion of converged users on the wireless (e.g. GSM) network. Overflow routing at the CS2K will allow an alternate route to ensure the GSM calls complete in the event the SIPT trunk connecting the MCS is detected as faulty.
12. The Converged Multimedia PC Client does not support Audio; must use the PAD.
13. A Converged User can only have one Multimedia PC Client active at any one time.
14. The MCS must interface a DMS based TDM switching system (CS2K).
15. A single Converged Phone Number can be assigned to a subscriber.

16. The Converged Multimedia PC Client is not aware of Service provided by the Switching System (e.g. Call Forward, Roll Over to Voice Mail).
17. Voicemail – A user should have one VM provisioned. For example, a user should not have VM provisioned on MCP and TDM switch. This can introduce unexpected behavior with the user's PA rules and VM pickup timing. For example, if a user has VM off of GSM network (for their mobile) and provisions a rule on their PA to ring their client (Mobile) 3 times, along with other destinations in their ring-list and their GSM VM is set for 3 rings, then their GSM VM could pick up and the remainder of the PA rules will not be run. The user may expect the PA rules to finish before their GSM VM picking up. Care must be taken on how ring-lists and VM are setup, so the desired behavior is seen.
18. Whenever Voicemail is hosted off TDM switch, MWI is not provided to converged users MCD PC Client.
19. When a MCD user appears in a Personal Agent ring-list the MCD user's redirect COS is not used when a call is extended to the user's converged phone. Instead, the MCD user's primary COS is used. This guarantees that a call to a MCD user will always be able to terminate to their converged phone. Because a MCD user's Preferred Audio Device (the number used to reach their converged phone) is provisioned by the administrator, fraud via redirect should not be a problem.
20. The mobile subscriber (PAD) cannot be part of a centrex group.
21. The mobile subscriber (PAD) can only have single line appearance. Either public or private but not both.
22. Client and network services provided on the wireless TDM network are not coordinated with those provided by the MCS 5200. Each network provides its services independently such that wireless features invoked on the CD Mobile (PAD) will not supervise the MCS Session Manager or its clients.
23. The only originating service supported in this release is click-to-call.
24. If Branding is provisioned, the mobile subscriber may hear branding multiple times during call setup on the PAD. Specifically, branding media files will be played for each call leg into the MCS application server.
25. Telephony translations that involve the prefixes CRD or CRA should be avoided. The CD service will prefix the destination accordingly.
26. Personal Agent routes can not be used to screen converged users PAD number or SIP user ID.
27. This feature does not support MCD PADs accessed from the MCS via a PRI gateway.
28. The Picture ID functionality will ONLY work if a call is made from an MCD PC Client SIP client using SIP addressing. If the call is routed through the GSM network then the picture ID information will be lost.

20.7 Feature Interaction

20.7.1 Service Compatibility

This feature is not compatible with various other MCS services. A summary of service compatibility is provided in the following Table. Service packages that contain the Converged Desktop feature can not be provisioned with any service indicated as ‘Not Compatible’ in the following table.

Table 21 Service Compatibility

MCS Service	Interaction with Converged Desktop Service
Ad Hoc Conference	Compatible - Subscribers can invoke MCS Conferencing by Joining established calls.
Advance Address book	Compatible - This is used by the “Converged” client to save other subscribers calling information. The address book can be used to originate calls.
Advance Screening	Compatible - This provides the advanced routing and screening capabilities from the MCS Personal Agent.
Allowed Clients – PCClient Set Control	Not Compatible
Assistant Console	Not Compatible - not used by MCD users
Assistant Support	Not Compatible - not used by MCD users
Call Park	Not Compatible - MCD users cannot park or retrieve calls while converged, but the call from a MCD user can be parked
CS2000 SIP Line	Not Compatible - not used by MCD users
Calling Line ID Restriction	Compatible - This service is applied when using the C2C in the “Converged Mode” or using another MCS client for origination of calls from the MCS system. If Calling line restriction is required from a TDM phone then this service would need to be provisioned on the TDM switch providing the service to the phone.
Call Waiting Disable	Not Compatible
Client Collaboration	Compatible – However, all forms of client collaboration are applicable to only MCS subscribers.
Colorful Ringback Tones	Not Compatible
Converged Desktop	Compatible - Set to the following for MCD service “Mobile converged”
Device Access Restrictions	Not Compatible
Hot Line	Not Compatible
Multiple Login Restriction	Not Compatible
Net6 Support on 2004	Not Compatible
IM Chatroom Meet Me conferencing	Compatible - can be assigned to a MCD user to access conferencing bridge and MCS chat room.

Table 21 Service Compatibility

MCS Service	Interaction with Converged Desktop Service
Music On Hold	Compatible – Can be used in most call scenarios where the call traverses the MCS system.
Network Call Logs	Compatible – However, call logs originated from the PAD will not be logged in the ‘outbox’. However calls originated from the MCD PC Client (via click-to-call) will be logged to the call log ‘outbox’.
Presence	Compatible – However, presence of a MCD user is based on the MCD Client registration. If the MCD Client is not registered, presence of the MCD user is not updated.
Qos	Not Compatible
Subscriber OPI	Compatible
Unified Communication	Compatible – MCS / MAS hosted voicemail
Video	Not Compatible
Voice Mail	Compatible - TDM based voice mail.
Wireless Client	Not Compatible
Wireless Gateway	Not Compatible

The following sections describe the interactions of Wireless Converged Desktop service with other supported features that may exist on a converged call. Services not listed are not supported in this release.

1.7.2 Advanced Routing

No special handling is required for sequential or simultaneous calls that include a Converged User.

1.7.3 Voice Mail

Calls that terminate to a MCD PC Client can forward to a Voice Mail system. There are two approaches that can be taken to accomplish this.

The first approach is to have the user continue to use their mobile based voicemail. In this configuration the MCS application server will release these call attempts and the CS2000 must map this release to an ISUP message REL w/ cause. The call can then be further processed on the mobile network to forward the call to a voicemail system.

The second approach is to transition users to an MCP based voice mail system. If an MCP based messaging system is used, then both call legs of the dual leg call to a MCD User are cancelled, and the call is rolled over to the voice messaging system.

1.7.3.1 Voice Mail Hosting

It is recommended that the MCP handle Voice Mail roll over instead of the mobile switching system. This will allow the Personal Agent to search the subscriber's other terminating devices before rolling over to Voice Mail. Doing this may take additional resources because the switching system will have to send all calls to the MCP so that voicemail can be handled.

1.7.3.2 Voice Mail Waiting Indicator (MWI)

If the voice messaging system is hosted off of the MCP the MCD Multimedia PC Client provides a voicemail indicator. The voicemail icon at the top will flash when a new unread message is in your inbox and will stay flashing until the message has been retrieved. VM MWI is not provided if VM is hosted on the TDM system.

1.7.3.3 Voice Mail Access

The MCD user can access their voicemail box by making a call to the voice mail number on the MCD Multimedia Client (which is through the click to call mechanism) or dialing the number on the Converged phone directly. After the call is established, the user can then navigate the voicemail system and retrieve their voicemails using their Converged Phone keypad. The MCD Multimedia Client cannot be used to do this (unlike the non-converged Multimedia PC Client which can). Double-clicking on the voice mail icon does not call the voice mail server on the mobile network.

1.7.4 Interaction with IM and Web push

Instant Messages or Web pushes received by a SIP user are directed to the MCD Multimedia PC Client only.

1.7.5 Multiple Call Restriction

The maximum number of simultaneous calls is enforced on the MCS Session Manager during call processing.

1.7.6 Presence

Presence is available only on the MCD Multimedia PC when registered. The enhancement called "On the Phone" presence (automatically changes state if the client is engaged in an active call) is not available in this release. For example, if a call originates from the CD Mobile the presence state will not change to "On the Phone" at the PC Client. However, presence states can be manually changed on the MCD PC Client. The standard list of presence states are supported along with any user defined states. Please refer to the "SIP Multimedia PC Client Fundamentals" user documentation for information on Presence for the Multimedia PC Client.

1.7.7 Call Redirect (before answer)

Redirect before answer is not available to a MCD PC Client, but the MCD PC Client and its Converged Phone (PAD) can be redirected by another MCP client before answer.

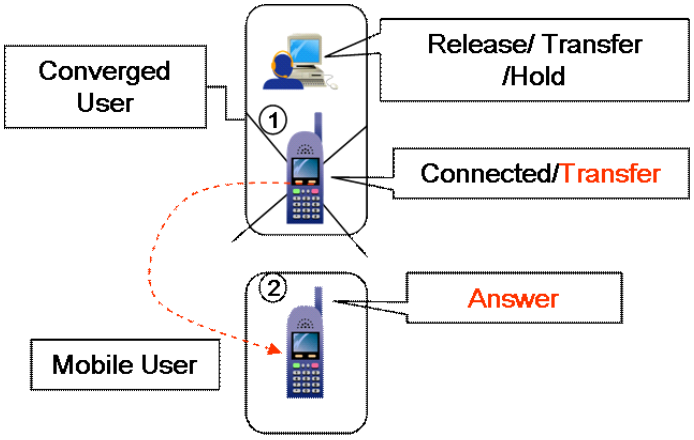
1.7.8 Call Transfer

Direct Transfer after answer is available to the MCD PC Client. When the 'transfer' button is clicked, the subscriber will be shown a window for entering the destination the call should be transferred to and only offers the option to perform a direct transfer. If a direct transfer is invoked, the client will send a SIP REFER message to direct the call to the transfer destination and the call on the PC client is released once the transfer is complete.

Consult Transfer is not available to the MCD PC Client. However the MCD PC Client and its Converged Phone (PAD) can be transferred by another MCP client.

The call-transfer features on the mobile phone may have undesirable side effects when used in conjunction with the MCD feature offered by MCS. Generally, the MCS will not have knowledge of the mobile invoked features. Consider the following scenario which may occur as these features intersect. Figure 43 shows Converged User already engaged in a conversation with a party B (not shown). However, when a transfer is invoked from Converged User's mobile phone to Mobile-2, the voice path will be modified on the mobile network without knowledge of this transition on the MCS network. Thus, resulting in a scenario where the MCD PC Client can control the audio stream of the transferred call even when the audio is changed over to Mobile-2.

Figure 43 Call Transfer from Mobile



1.7.9 Conference Calls

Conference calls are supported on the MCD PC Client.

1.7.10 Meet Me Conferencing

Meet me conference calls are supported on the MCD PC Client.

1.7.11 Caller Line ID (Privacy)

Caller Line ID Privacy is supported on the MCD PC Client and the MCS network. However, the feature must also be enabled on the TDM network at the same time to be effective.

1.7.12 Network Call Logs

1.7.12.1 Inbox

Inbound call attempts are recorded in the Inbox. The ability to successfully re-dial a caller from this call log depends on the calling line id provided by the adjacent switch (CS2K). The prefixing introduced in this feature will be automatically pre-pended by the application server during call routing.

1.7.12.2 Outbox

Only outbound call attempts made from the MCD PC Client are recorded in this Outbox. Outbound call originations from the PAD will not be recorded in this log.

1.7.13 Interaction with RTP Portal

RTP media portal will not be inserted even when the MCD PC Client is behind a firewall.

1.7.14 Interaction with Long Call Audit

Call audits that involve the PAD leg (CD mobile) will simply be forwarded to the CS2000. The MCS Session Manager will not release these call legs directly.

1.7.15 Interaction with Other Media Services

The following services depend on the MAS for providing media.

1.7.15.1 Branding

MAS hosted branding is supported on the MCD PC Client.

1.7.15.2 Colorful Ring-back Tones

CRBT is not supported the MCD PC Client.

1.7.15.3 Music On Hold

MAS hosted music-on-hold is played to all parties on hold (when provisioned).

1.7.15.4 Announcements and Treatments

MAS hosted announcements are not played to a gateway subscribers. Thus, mobile subscribers will not be able to hear these media files on the mobile.

1.7.16 Class of Service considerations for MCD Terminations

When a call terminates to a Converged User, a call leg is extended to the user’s converged phone over a gateway route using the Preferred Audio Device DN

that is provisioned for that user. The rules for determining the class of service and dial-plan for processing of the Preferred Audio Device DN are as follows.

When calling within the same domain or across different domains, translations uses the dial-plan of the domain that is being terminated to and the class of service of the Converged Desktop User that is being terminated to.

1.8 Accounting

1.8.1 Converged Desktop Supplementary Service

This feature introduces a new supplementary service to the IPDR. The serviceType field will be labeled “mobileConverged” if this service is running on the call leg that the record is generated on.

1.8.2 IPDR (Internet Protocol Detail Record)

There are some important aspects of the IPDR records generated by the Converged Desktop feature that need to be understood to ensure proper billing can be provided. The following sections describe how accounting for this service is different than normal MCP based calls.

1.8.2.1 Number of Billing records on a Converged Call

The general accounting rules for generating IPDRs apply to Mobile Converged Desktop. The only scenario where the MCD service deviates from the normal policy is when the MCP creates two separate legs for a ‘converged’ call (one for Mobile and one for PC Client). In that case, the two legs are treated as one and only one record set (i.e. CI/DI or CE/DE) is created to represent both legs of the call.

1.8.2.2 Mid-call (event based) SDP IPDR

On a converged call, when mid-call audio changes occur, each leg on a Dual Leg will generate an SDP IPDR for the stream type it handles. The audio leg will generate an SDP IPDR containing only audio SDP if the audio stream has changed. Additionally, when the PAD audio is modified through the CS2000 the MCS will generate SDP IPDR records.

1.8.2.3 MCP / TDM billing record correlation

All IPDR records generated by a converged call, including the extra IPDRs generated on a Dual Leg call, will have the “corrID” IPDR field set to the same value so that they can be records. This field can be used to correlate records from converged calls on the MCP and the TDM switch.

If a correlation ID is passed to the MCP via the “x-nt-corr-id” header in an SIP INVITE from a TDM switch, then all IPDRs generated on that call will have the “corrID” field set to the value of the received correlation ID. In addition, if the call is extended back to a TDM switch (same switch or another), the same correlation ID is passed in the SIP INVITE to that switch via the “x-nt-corr-id” header.

1.9 Fault Management

1.9.1 Logs

N/A

1.9.2 Operational Measurements

The following Operational Measurements are added:

1. Each time a CD call is originated by click-to-call

```
    Component: Session Manager
     OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDC2C
        Range: Integer
   Definition: Counts the number click-to-call
originations that were placed from a MCD PC Client.
```

2. Number of call attempts answered on the CD Mobile (PAD)

```
    Component: Session Manager
     OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDANSPAD
        Range: Integer
   Definition: Counts the number call attempts that
were answered on the CD Mobile (PAD). This scenario
occurs when the subscriber is registered on the MCD
PC Client and the CD Mobile answers the initial call.
Thus, can also be considered the number of 'initial
calls answered'. The counter is incremented on the
successful SIP Notify transaction sent to the PC
client. This register will not peg if the subscriber
is not registered on the MCD PC client.
```

3. Each time a call attempt is answered on the MCD PC Client

```
  Component: Session Manager
     OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDANSPCC
        Range: Integer
   Definition: Counts the number call attempts that
were answered on the MCD PC Client. This scenario
occurs when the MCD Client answers the initial call.
Thus, can also be considered the number of
'subsequent calls answered'.
```

4. Number of call attempts to MCD PC Client when client becomes network isolated

```
    Component: Session Manager
     OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDCOG
        Range: Integer
   Definition: Counts the number call-of-grace
terminations that were attempted on a MCD PC Client.
This scenario occurs when a MCD PC Client has a
registered contact on the MCS application server, yet
fails to auto-answer an incoming call attempt. The
behavior at the application server is to attempt this
call-of-grace 1 of N call attempts.
```

5. Number of call attempts redirected to PSTN when MCD PC Client is not registered

```
    Component: Session Manager
     OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDPXYCALL
        Range: Integer
   Definition: Counts the number call attempts that
were proxied back to the CS2000. This scenario occurs
when a MCD PC Client has not registered on the MCS
```

application server. All call attempts should be proxied back to the mobile network.

6. Each time a call attempt timer expires on the application server for a CD3 subscriber.

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDCATTEXP

Range: Integer

Definition: Counts the number of termination attempts presented to MCD PC Client, where the call attempt timer expired. The call was presented to the subscriber but no action was taken. The application server releases the call upon expiry.

7. Each time a call termination attempt is Rejected / Declined by a CD3 subscriber

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDDECLINE

Range: Integer

Definition: Counts the number of declined termination attempts that were presented to MCD PC Client. The subscriber must press ‘Decline’ for this register to increment.

8. Each time a call termination attempt is Ignored by a CD3 subscriber

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDIGNORE

Range: Integer

Definition: Counts the number of ignored termination attempts presented to MCD PC Client. The subscriber must press 'Ignore' for this to register to increment.

9. Each time a call hold / retrieve is attempted by a CD3 subscriber

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDHLDRT

Range: Integer

Definition: Counts the number of hold/retrieve attempts managed by the CD3 service.

10. Each time a call transfer is initiated by a CD3 subscriber

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDXFER

Range: Integer

Definition: Counts the number of call transfers managed by the CD3 service.

11. Each time a conference call is initiated by a CD3 subscriber

Component: Session Manager

OM group: CONVERGEDDESKTOP3_SERVICE

Tuple Name: ConvergedDesktop_Service

Register Name: CDCONF

Range: Integer

Definition: Counts the number of conference calls managed by the CD3 service.

12. Each time MCD PC Client Register message is received

Component: Session Manager

```
      OM group: CONVERGEDDESKTOP3_SERVICE
   Tuple Name: ConvergedDesktop_Service
Register Name: CDREG
        Range: Integer
  Definition: Counts the number of register messages
that are sent by the MCD PC Client during Login,
updates, and Presence state changes.
```

139: Functional Description (FN) A00012273

139.1 Feature name and Feature ID

A00012273 - SIP Lines: Call Forwarding Indication

139.2 Description

This activity provides the CS2K support for Call Forwarding Indicator and Call Forwarding Reminder for SIP agents that interface to the CS2K

Note that this functionality also requires SIP Client development in the SIP messaging arena, which is not covered by this activity.

Call Forwarding Indicator is provisioned using option CFIND. The SIP client provides a special dialtone (sometimes called “stuttered dialtone”) to a subscriber who goes offhook when the subscriber has had call forwarding activated.

Call Forwarding Reminder provides a brief one-time ringing (sometimes called “ring splash”) to a subscriber who is onhook when call forwarding is active and a call was attempted to the subscriber and forwarded.Enabling/ Disabling of Call Forwarding Reminder is not provisioned as a separate option, but is dependent upon the type of call forwarding and also possibly feature data for some call forwarding types. For example, Call Forward Busy (CFB) never has Call Forwarding Reminder, while Call Forward Universal (CFU) always does, and Selective Call Forwarding (SCF) has feature data indicating if it does.

139.3 Hardware Requirements or Dependencies

None

139.4 Software Requirements or Dependencies

None

139.5 SIP User Agent Interactions & Requirements

If the SIP User Agent (UA) is not registered, calls attempting to terminating to it are unaffected by this feature.

If the UA does not respond to an INVITE, calls attempting to terminating to it are unaffected by this feature.

If the UA rejects an INVITE, calls attempting to terminating to it are unaffected by this feature.

In order to support this feature, the UA must be compliant to draft-ietf-sipping-config-framework-07 (ua-profile event package). The ua-profile event package deals with the call forwarding indicator. Additionally, there is a new event package defined by this feature for the call forwarding reminder.

139.5.1 Call Forwarding Indicator

The syntax used for the call forwarding indicator:

SUBSCRIBE
Event: ua-profile
Accept: application/server-call-feature-status+xml

NOTIFY
Event: ua-profile
Content type: application/server-call-feature-status+xml
Content:
<ua-profile>
<feature>call-forward-indicator</feature>
<status>on | off</status>
</ua-profile>

When call forward is activated, every subsequent origination attempt should get a distinctive dial tone (stutter dialtone).

139.5.2 Call Forwarding Reminder

The new event package deals with the call forwarding reminder. The syntax:

SUBSCRIBE
Event: network-redirection-reminder
Accept: application/network-redirection

NOTIFY
Event: network-redirection-reminder
Content type: application/network-redirection
Content:
call-redirected | subscription-active | subscription-expired

When the call forwarding reminder is activated, if the UA has no calls, there should be a short alerting tone or message presented at the user interface.

139.6 Limitations and restrictions

Option CFIND (in SERVORD) for DPL lines must have feature data STN_TONE set to “CFT”. This is an existing limitation for all types of LGRP lines, which includes DPL lines.

139.7 Interactions

None.

139.9 Glossary

Term	Description

139.10 Sample Datafill & Usage

For both call forwarding indicator and call forwarding reminder, it is necessary to have call forwarding datafilled on the line. A sample SERVORD command for call forwarding on DN 5200001 (assuming a RES line):

```
ADO $ 5200001 CFW C NSCR 1 $
```

For call forwarding indicator, it is also necessary to have the CFIND option datafilled. CFIND is a RES option. A sample SERVORD command for CFIND on DN 5200001 is:

```
ADO $ 5200001 CFIND CFT 1000 $
```

With the above datafill, after the subscriber activates call forwarding:

- A stuttered dial tone is given to the subscriber when going off-hook
- When a call is placed to 5200001 and is forwarded, the SIP device will generate a ring splash.

140: Functional Description (FN) A00012308

140.1 Feature name and Feature ID

A00012308 - SIP Lines Services: PRK, DPRK, CPU

140.2 Description

The purpose of this feature is to interwork a specific set of Session Initiation Protocol (SIP) clients into IBN/RES network based Call Park and Call Pickup services. See “Limitations and restrictions” on page 1397. for the specific list of Call Park and Call Pickup line options.

To activate this feature functionality the service set 1 patches need to be applied and DPL line option compatibilities removed (included in patches). Once applied, the setup and functionality of these services with SIP agents are seamless as compared to the functionality of the service on other Nortel supported agents For additional information reference Nortel NTPs for Park and Pickup NT-297-8001-808.

140.3 Hardware Requirements or Dependencies

There are no hardware dependencies required to execute this feature.

140.4 Software Requirements or Dependencies

Software Dependencies:

— XACore Succession release SN10 and SN09 patches

Firmware Dependencies:

— none

140.5 Limitations and restrictions

- Supports the following Call Park and Call Pickup line options:
  - — Call Park: PRK, DCPK
  - — Call Pickup: CPU, DCPU, DCPX, TAFAS
- Supports the following set of SIP devices:
  - — Motorola Outside Network Terminations (ONTs)
  - — Cisco SIP phones
  - — Nortel PC Soft clients

- Supports the existing Engineered Recommended and Absolute group member maximums for Call Pickup (CPU) when all members are SIP agents.
- This feature supports Parking a call if there is at most one other answered session when the Call Park vertical service code is processed.
- In the context of Call Pickup (CPU), the number of sessions which could be simultaneously alerting will vary based on the client. The CS2K Pickup service will always pickup the session which has been ringing the longest.
- In the context of TAFAS Pickup (TAFAS), if the TAFAS agent is a SIP agent, then multiple terminations are possible with the proper datafill. If more than 1 termination to the TAFAS SIP device is occurring, then the longest ringing TAFAS SIP session will be pickup.
- Activations for CPU, additional session invocation of CPU are subject to current CPU flash invocation restrictions.
- Activations for DCPU, additional session invocations of DCPU are not allowed if currently involved in a stable (talking) call. This matches current DCPU behaviors...i.e you cannot flash and invoke DCPU.
- Activations for TAFAS, additional session invocation of TAFAS are subject to current TAFAS flash invocation restrictions.
- Interactions with CPU, DCPU, and TAFAS, and call wait (CWT). A call waiting call will not be picked up. This is done to match historical behavior.
- Directed Call Pickup w/Barge-In and Directed Call Pickup w/Barge-In Exempt will be delivered in a separate activity. Until this is delivered, invoking of Barge-in via a SIP agent or Barging into a SIP agent is not supported.

140.6 Interactions

The following are the feature interactions for this feature:

- Features which this feature is dependant on:
  - — none
- Features which are dependent on this feature:
  - — A00012597 Music On Hold
  - — A00012323 Park/Pickup w/Barge-in
- Features which have an interaction with this feature:
  - — none

140.8 Glossary

Term	Description
Features	in this context means design feature as opposed to central office features/services (ex. CFW, CWT, etc.)

141: Functional Description (FN) A00012310

141.1 Feature name and Feature ID

A00012310 - Hunt, SCMP, and CWT variant support for SIP Lines

141.2 Description

The purpose of this feature is to provide support for network based hunting, series completion and call waiting services for SIP user agents as part of the CS2K SIP Lines program.

In general,these services will behave in a manner consistent with their behavior in non-SIP configurations. Any exceptions are noted below.

141.2.1 Hunting

This feature provides support for the following hunt types on CS2K SIP Lines:

- DNH - Directory Number Hunt
- MLH - Multi-Line Hunt
- DLH - Distributed Line Hunt
- BNN - Bridged Night Number
- PRH - Preferential Hunt

In addition, the following hunt suboptions will be supported:

- CFGD/CFGDA - Call Forward Group Don’t Answer
- LOD- Line Overflow to DN
- LOR - Line Overflow to Route
- CIR - Circular Hunt
- SHU - Stop Hunt
- RMB - Remote Make Busy

SIP lines can be used in the same hunt group as non-SIP lines. There will be no restrictions on using SIP lines in hunt configurations beyond the normal customer group and line class code restrictions imposed by standard hunt provisioning.

The functionality for SIP lines being in hunt groups has been defined to be:

- Termination on a SIP line for hunt purposes will only be considered if that line is involved in no other calls at the time. That is, the SIP line will be

skipped in the hunt search algorithm if it is already involved in a call - even if it has the capability to engage in multiple call appearances.

Exceptions:

1.) CWT termination is allowed in DNH and PRH groups if the individual member has the CWT option. For SIP lines, if a DNH or PRH member has CWT, hunt calls will continue to be presented to the member until its maximum call appearances have been reached.

2.) In MLH configurations, if CWT is added to the pilot, extra call waiting calls are actually presented to the last member of the group. If that last member is a SIP line, calls will continue to be presented to that line until its maximum call appearances have been reached.

- If a hunt call terminates on a SIP line, and the SIP client declines the call (4XX or 6XX SIP response), the hunting search will continue to the next available hunt member. BNN groups are an exception to this rule. When a call terminates on a BNN and the SIP client declines the call, the call will receive busy treatment.
- If a hunt call terminates on a SIP line, and the SIP client redirects the call (3XX SIP response), the call will be forwarded to the redirection destination.
- Hunt suboptions CFGD/CFGDA, LOD, LOR, CIR, SHU, and RMB will function in the same manner as they do in non-SIP configurations.

141.2.2 Series Completion (SCMP)

This feature provides support for Series Completion on CS2K SIP Lines.

SIP lines can be in the same SCMP group as non-SIP lines. There will be no restrictions on using SIP lines in SCMP configurations beyond the normal restrictions imposed by standard SCMP provisioning.

In general, SCMP on a SIP line should function in exactly the same manner as it does for a non-SIP line. There are two items worth noting:

- SCMP takes precedence over CWT. Therefore, termination on a SIP line for SCMP purposes will only be considered if that line is involved in no other calls at the time, even if it has the capability to engage in multiple call appearances.
- SIP lines have the additional capability to decline calls after they have been presented to the line. If a SIP line with SCMP is idle but declines the call, the call will be directed to the SCMP DN rather than busy treatment.

141.2.3 Call Waiting Variants

This feature provides support for the following Call Waiting Variants on CS2K SIP Lines:

- CWI - Call Waiting Intragroup

- CWO - Call Waiting Originating
- CWD - Dial Call Waiting
- CWX - Call Waiting Exempt
- CWTACT - Call Waiting Activate
- SCWID - Spontaneous Call Waiting Identification

For SIP lines, a call waiting call is just a second call appearance being offered to the SIP client. The client is responsible for any tone application and the function of switching between the two calls via hold/restore. Therefore, for CS2K SIP lines, the presence of the above CWT options will be used to determine when it is appropriate to offer multiple call appearances to the terminating SIP line.

In that context, the function of the above CWT variants is the same for SIP lines as it is for non-SIP lines.

141.3 Hardware Requirements or Dependencies

CWD requires PMA (Packet Media Anchor) insertion when the CWD originator is a SIP line. The PMA is required to provide subsequent digit collection after the CWD feature access code. Without the PMA, CWD cannot be initiated by a SIP line.

141.4 Software Requirements or Dependencies

In order to provision hunt groups on CS2K SIP lines, there is a dependency on feature A00012223: “SESM Additional Provisioning for SIP Lines”. This feature adds support for hunt group provisioning commands such as EST, ADD, DEL, ABNN, DBNN, and CHDN via SESM.

141.5 Limitations and restrictions

- MPH (Multi-Position Hunt) is not supported by this feature.
- Hunt group provisioning commands EST and ADD, when applied via SESM, will be limited to only one len or gateway endpoint per command. See feature A00012223 “SESM Additional Provisioning for SIP Lines” for more information.
- CWR (Call Waiting Ringback) and CWTC (Call Waiting Conference) are not supported by this feature.
- If a SIP line has max_call_appearances set to 1, then no call waiting calls can be presented to that line by any call wait variant, regardless of CWT variant provisioning.
- If a SIP line is using all of it’s available call appearances (example: max_call_appearances = 4, and 4 calls are active), then no further calls can

be presented to that line by any call wait variant, regardless of CWT variant provisioning.

- Typically, core based features that impose call waiting on the terminating line (CWO, CWD) will override the use of Cancel Call Waiting (CCW) by the terminator. For SIP lines however, CCW is implemented in by the SIP client, so core based CWO and CWD cannot override it. This is a limitation of CWO and CWD for SIP lines.

142: Functional Description (FN) A00012315

142.1 Feature name and Feature ID

A00012315 - Telemetry for SIP Lines

142.2 Description

The SIP Lines Telemetry feature (A00012315) enables remote meter reading of SIP Lines. It allows utility companies to read utility meters remotely by establishing a media session with the Telemetry device at the subscriber's home.

This feature allows the functions of the UTS (Utility Telemetry Service) and SRA (Suppressed Ringing Access) CS2000 Core features to be extended to SIP Lines. UTS and SRA calls are established from automated systems owned by utility companies to TIU (Telemetry Interface Unit) devices that are attached to the subscriber's phone line. Both UTS and SRA suppress ringing of the subscriber's phone and allow the TIU to pick up the call.

To operate on SIP Lines, the customer has agreed that SIP INVITE messages will be sent to the ONT with appropriate headers added. The SIP User Agent, running inside the ONT, will route calls with the new telemetry headers to the TIU instead of the phone.

The media session of the Telemetry call is set up using the G.711 codec so that any specific in-band signalling between the utility company and the TIU can be transported.

The major requirement of this feature is flagging Telemetry calls so that appropriate headers can be added to the outgoing INVITE to the ONT.

The figure below illustrates the flow of a typical Telemetry call. The messages between the Utility Company Server and the CS200 are moving over either UT or ISUP trunks. Generic trunk messages are shown as UT and ISUP trunks use different messaging.

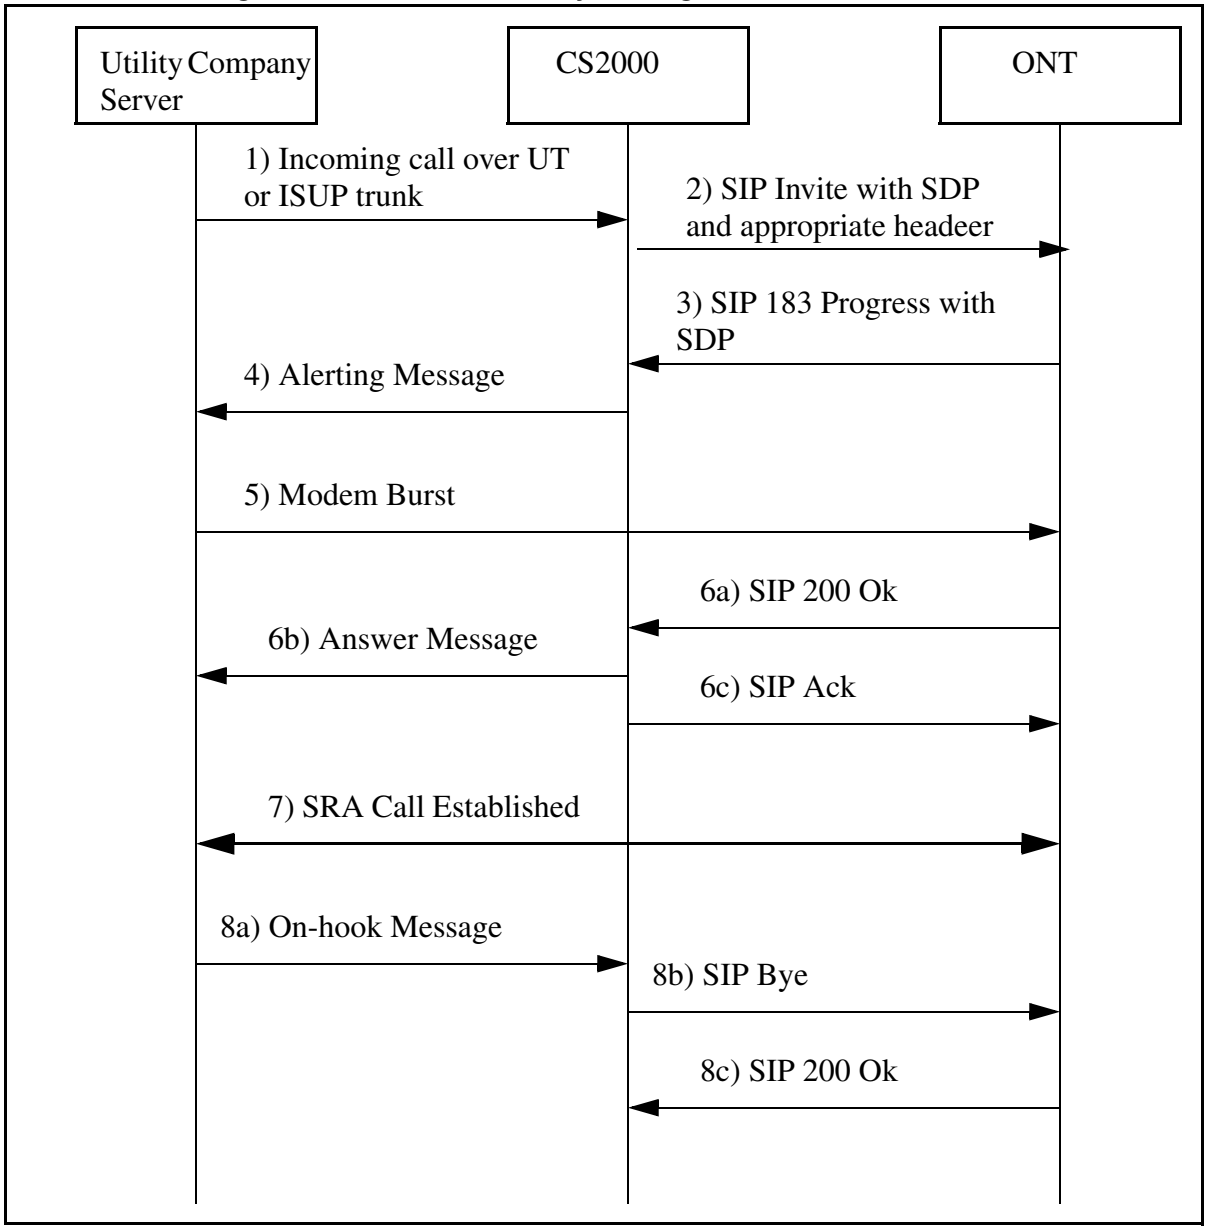
1. An incoming Telemetry call, which can either originate on a dedicated UTS-trunk or travel over an ISUP trunk, reaches the terminating CS2000. For ISUP trunks, this will be a IAM message; for UT trunks it will be an off-hook message followed by digits messages.
2. If the terminating line is a SIP line (has the DPL line option), a SIP Invite message is sent to the ONT. The INVITE contains the Require header "Require: x-suppressed-ringing". If the telemetry call is interruptible, resource-priority header will be added: "Resource-Priority: x-suppressed-

ringing.interruptible". If open-loop is configured, x-suppressed-ringing header will be added: "x-suppressed-ringing: open-loop=<value in seconds>"

The ONT, seeing the headers, knows this is a Telemetry call.

3. The media path must be established before the answer messages for Telemetry calls because the utility company servers send a modem burst which they expect to cause the ONT to go off-hook. For this reason, the initial SIP Invite will have SDP included. The ONT must send a 183 Progress message with SDP in response.
4. The CS2000 informs the originator that the media path is complete. For ISUP this will be a ACM message; for UT, a wink message is sent.
5. The originating server sends a modem burst to wake up the TIU off the ONT.
6. The ONT sends a 200 OK message which results in a answer message being sent to the originator. For ISUP, this is a ANM message; for UT, an off-hook. The CS2000 also sends an ACK back to the ONT.
7. At this point, the Telemetry call is up and the originating server interrogates the TIU.
8. In the usual case, the server initiates call shutdown by sending a on-hook message. This is communicated to the ONT via a SIP Bye message. The ONT acknowledges the Bye via a 200 Ok.

Figure 1 Common Telemetry Message Flow



142.2.1 CS2000 Core Provisioning

No new provisioning steps are introduced by this feature on the CS2000 Core. Some background on Telemetry may be useful however.

Telemetry calls are initiated from servers owned by utility companies. The calls can be completed in 2 ways: via the UTS or SRA methods.

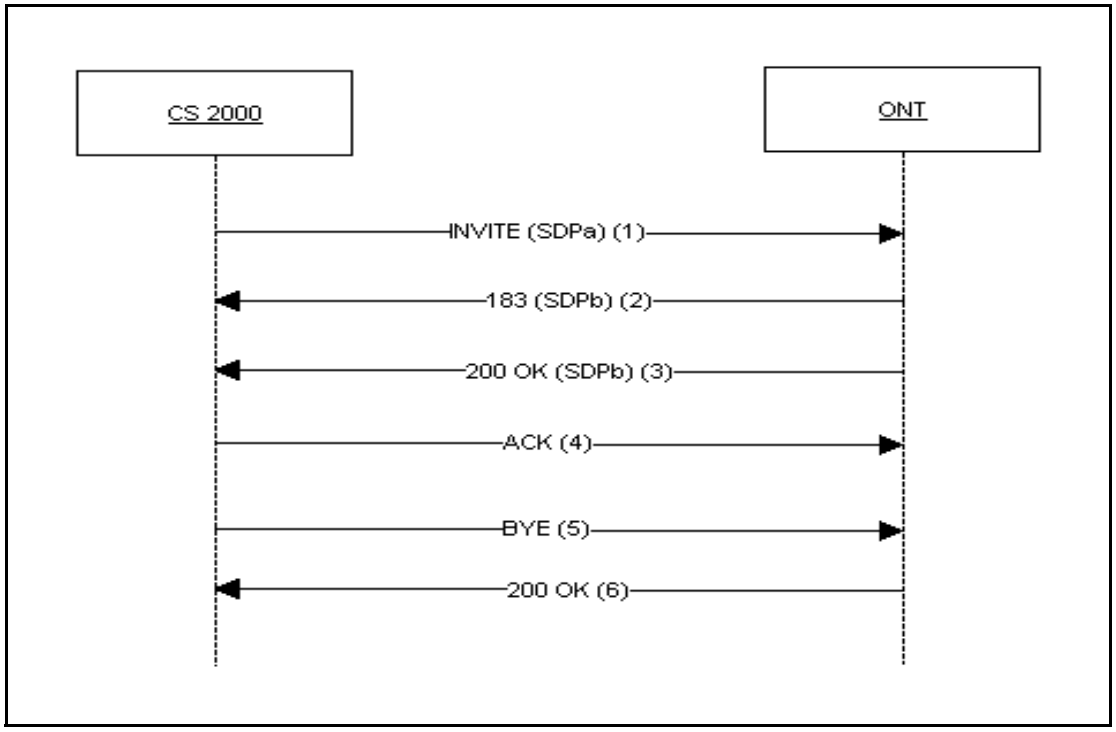
UTS Telemetry calls are made over dedicated UT trunks which directly connect the utility company servers to the terminating CS2000. When a call

arrives over a UT trunk, the UTS feature on the CS2000 suppresses ringing to the terminating line and connects the call.

SRA Telemetry calls have the same end result, suppressing ringing to the line, but can be initiated over ISUP trunks. In an SRA call, the originating server doesn't need to be directly connected to the terminating CS2000. SRA calls translate to a feature DN in table DNROUTE which starts the SRA feature. The SRA feature does some security screening, then extracts the subscriber's DN from the OCN parameter of the IAM message. It then ensures that the SRA line option is on the terminating line. Alternatively, Universal SRA can be enabled for the entire office.

142.2.2 Message Flow between CS2000 and the ONT

Figure 3: Telemetry Call Flows



The INVITE message will be changed as the part of this feature. The required changes are in bold text.

INVITE (from Session Manager to ONT), URI parameter and Require header added.

142.2.3 CPL Processing for telemetry call (Session Server)

CPL processing will be disabled for telemetry call since telemetry call is used do remote meter reading. It's not appropriate to forward Telemetry call to other devices such as cell phones or other telephone numbers.

142.3 Hardware Requirements or Dependencies

No new hardware dependencies are introduced beyond the existing requirements for Telemetry calls and SIP Lines.

142.4 Software Requirements or Dependencies

No new software dependencies are introduced beyond the existing requirements for Telemetry calls and SIP Lines.

142.5 Limitations and restrictions

- The CS2000 Session Server's branding/treatment will be disabled for Telemetry calls.
- The CS2000 Session Server's CPL processing will be disabled for Telemetry calls.

142.6 Interactions

Telemetry calls have documented interactions with other CS2000 voice features. Most of these interactions effectively disable other terminating features (such as Call Forwarding, SCRJ, etc). The UTS FN, found in PLS FMDOC under node NC0362FN, details these interactions.

The UTS and SRA Core features can be provisioned to be interruptible or non-interruptible. Traditionally, if a Telemetry call is interruptible, another incoming call to the terminating line will take precedence over the Telemetry call. This is accomplished by the CS2000 suspending the incoming call while it tears down the Telemetry call. However, SIP lines can support multiple call appearances. It has been decided, in agreement with the customer, that if a line is busy with a Telemetry call, subsequent incoming calls will always be offered to the line via a new SIP session.

The SRA Core feature has a *ACCESS* field in its DNROUTE tuple which can be set to NORING, OSI or RING. However, for DPL lines, the client (the ONT in this case) is responsible for ringing the line. As the values of the ACCESS tuple are not communicated to the client, the datafill in ACCESS will have no effect on DPL lines. It is expected that the clients will not ring the line for Telemetry calls.

A couple other interaction scenarios deserves mention. The first involves the Call Forward Don't Answer (CFD) feature. If a second call is established to a ONT line that is busy with a non-interruptible Telemetry call, the ONT will return a SIP 486 Busy message, not a 180 Ringing message. CFD will not be invoked and the call will not forward; the originator will not hear busy tone.

The second interaction involves a Telemetry call to a ONT line that is already busy with a call. Again, the ONT returns 486 Busy, not 180 Ringing. In this case the call will not complete; however, the originator will not get a busy tone.

Also note that call routing features (Personal Agent features) of the CS2K Session Server (MCS) are disabled on Telemetry calls.

142.7 Glossary

Term	Description
Telemetry	The science and technology of automatic measurement and transmission of data by wire, radio, or other means from remote sources, as from space vehicles, to receiving stations for recording and analysis.
UTS	Utility Telemetry Service
SRA	Suppressed Ringing Access
TIU	Telemetry Interface Unit

Term	Description
ONT	Optical Network Terminator

143: Functional Description (FN) A00012317

143.1 Feature name and Feature ID

A00012317 - Session Initiation Protocol (SIP) Services - Automatic Call Back (ACB) and Automatic Recall (AR)

143.2 Description

This activity provides support for Automatic Call Back (ACB) and Automatic Recall (AR), collectively called ACBAR, for Dynamic Packet Lines (DPL) using SIP.

The ACB service places a call to the last outgoing number dialed by the subscriber. The AR service places a call to the last incoming call to the subscriber. These numbers are stored in the outgoing and incoming call memories respectively.

If the number to be dialed (destination line) is busy, the CS2000 provides an announcement to the ACBAR subscriber, indicating that the line is busy, and that he will be notified with special ringing when the destination line is free. The CS2000 monitors the destination line until it goes idle. The CS2000 then rings the ACBAR subscriber, with a special ringing cadence indicating that it is an ACBAR recall notification. The number of the destination line may also be displayed on the ACBAR subscriber's phone, giving him an indication of which line is now free, as the ACBAR subscriber can have multiple ACBAR instances active.

When the ACBAR subscriber answers the notification, the CS2000 performs a final busy/idle check on the destination line, to make sure it has not gone busy within the interval of recalling the ACBAR subscriber. If the destination line is still idle, the CS2000 places the call to the destination line. If the destination line is busy again, the CS2000 provides an announcement indicating the condition, and that the ACBAR subscriber will be notified with special ringing when the destination line is free. This behavior continues until the call is placed successfully to the destination line, or the ACBAR subscriber cancels the ACBAR request, or the T6 or T10 timer expires indicating that the CS2000 has monitored the line for the maximum allowed time and automatically cancels the request.

Refer to BellCore/Telcordia TR-00215 and TR-00227 for information on the ACB and AR feature descriptions.

143.3 User Agent Requirements

In order to be integrated with the CS2000 ACB/AR service, the User Agent (UA) must be able to support the interface specified by this feature. A User Agent must be able to handle SIP Refer and Hold methods, and SIP Slow Start Termination procedures. To be able to provide the CS2000 ACB/AR service fully, they must also support caller id, distinctive ringing and name/number privacy. Supporting number privacy includes supporting a nested SIP p-asserted-identity header in the SIP REFER message.

The User Agent should not allow ACB/AR feature access codes to be used as the forward-to DN for User Agent based Redirection Services. The User Agent should not allow ACB/AR feature access codes to be used as the transfer-to DN as part of User Agent based Blind Call Transfer services.

143.4 Hardware Requirements or Dependencies

Not applicable.

143.5 Software Requirements or Dependencies

Not applicable.

143.6 Limitations and restrictions

143.6.1 AR To Busy Private Destinations

If the last number to call a SIP line was a private number, the SIP subscriber will be able to activate AR to that private destination DN if that DN is idle at the time of activation. If the destination DN is not idle at the time of AR activation by a SIP line, the AR request will not be honored, and the SIP subscriber will receive long term denial treatment. This is due to the fact that the REFER method is used to setup the call to a destination DN after that DN was busy, and subsequently went idle. The REFER method requires the destination DN be provided in the REFER method, as the REFER-TO number. This means that a private DN would be delivered to a User Agent, which is considered untrusted Customer Premise Equipment (CPE). Delivering Private DNs to CPE is an exposure to the privacy of the destination DN, and can lead to legal actions by the subscriber requiring privacy.

143.6.2 ACB To Busy Private Destinations

The same restriction described for AR in section 143.6.1, also applies to ACB. This is due to the fact that a SIP subscriber can successfully AR to a private destination DN. When this happens, the SIP subscribers outgoing call memory is updated with the destination's private DN. If the SIP subscriber subsequently activated ACB to the private destination DN, and that DN is idle, the ACB request will be honored and the call will go thru. However, if that private destination DN is busy at the time of ACB activation, the ACB request will not be honored, and the SIP subscriber will receive long term denial treatment for the same reasons described in section 143.6.1.

143.6.3 CNDB and ACB/AR For SIP Lines

If a SIP ACB subscriber has dialled the ACB access code to a busy destination, and either of the following conditions exists

1. prior to the last outgoing call, and the user dialed the CNDB access code, or,
2. prior to dialing the ACB access code, the user dialled the CNDB access code,

then ACB request will be honored, and the request will be queued. However, when the destination line goes idle, and the ACB user is recalled and answers the recall, the subsequent call that is setup to the destination line will have both the number and the name of the ACB user marked as private.

If a SIP AR subscriber has dialled the AR access code to a busy destination, and prior to dialling the AR access code the user dialled the CNDB access code, then AR request will be honored, and the request will be queued. However, when the destination line goes idle, and the AR user is recalled and answers the recall, the subsequent call that is setup to the destination line will have both the number and the name of the AR user marked as private.

143.6.4 ACBAR Provisioning Requirement

For ACBAR to be supported on a SIP User Agent, the User Agent must be provisioned with the SIP line option with at least at a value 2 for the MAX_NUM_CALLS field of the DPL Line option. This is a requirement due to the REFER mechanism used on Answer of the ACBAR recall ringing notification.

143.6.5 Redirect Attempts Using ACB/AR Vertical Service Codes

Use of ACB/AR feature access codes as the forward-to DN of a User Agent based Redirection Service is not supported by the CS2000.

143.6.6 User Agent Blind Transfer (REFER) Attempts Using ACB/AR Vertical Service Codes

Use of ACB/AR feature access codes as the transfer-to DN of a User Agent based Blind Transfer Service is not supported by the CS2000.

143.7 Interactions

143.7.1 ACBAR Interactions

Service Interactions involving SIP lines and ACBAR will be the same as those for non-SIP lines and ACBAR except where noted in this section.

143.7.2 Network Based Interactions

143.7.2.1 Destination Line - Network Determined Idle

If the CS2000 is monitoring a destination line for an ACBAR request, and that line is a SIP line, the line will be determined to be idle when there are no network based sessions for that line. User Agent based sessions and User Agent based services (e.g. Do Not Disturb) will not be taken into account by the CS2000.

143.7.2.2 ACB Subscriber - Network Determined Idle

If the CS2000 is about to recall notify a SIP ACBAR subscriber, that subscriber will be determined to be idle for recall when there are no network based sessions for that line. User Agent based sessions and User Agent based services (e.g. Do Not Disturb) will not be taken into account by the CS2000.

143.7.2.3 CLASS Call Memories

Incoming and Outgoing Call Memory (ICM, OCM) for a SIP subscriber will be updated in a consistent manner as normal CLASS and Centrex users. Only CS2000 handled originations and terminations will cause the Call Memories to be updated.

An exception is for User Agent based redirections. For User Agent based redirections (e.g. User Agent CFW), the OCM will not be updated by the extended leg to the remote DN. In other words, the OCM will not be updated to be the remote DN on a User Agent based redirection.

Click-to-Call feature operation will cause both the incoming and outgoing call memories to updated to the User Agent's own DN prior to answering the offered call at the User Agent's device. Once the offered call at the User Agent's device is answered, and call setup to the terminator occurs, the User Agent's OCM will be updated to the referred-to or dialed DN.

143.7.3 User Agent Interactions

143.7.3.1 ACBAR Distinctive Ringing

The ACBAR feature uses distinctive ringing for the recall notification to the ACBAR subscriber when the destination line is free. The distinctive ringing types used are specified in the following table:

Table 1 ACBAR Distinctive Ringing to SIP Alert Info mapping

SIP Alert Info Hdr	DMS Ring Code	NA Cadence (ms - 6 sec cycle)	UK & AUS Cadence (ms - 3 sec cycle)	DRING Datafill Ring Pattern
http://127.0.0.1/nortel/dst_ring_2	D	400 on, 200 off, 400 on, 200 off, 800 on, 4000 off	200 on, 200 off, 200 on, 400 off, 600 on, 1400 off	DRING 7

SIP Alert Info Hdr	DMS Ring Code	NA Cadence (ms - 6 sec cycle)	UK & AUS Cadence (ms - 3 sec cycle)	DRING Datafill Ring Pattern
http://127.0.0.1/nortel/dst_ring_6	4	1500 on, 500 off, 500 on, 3500 off	200 off, 800 on, 200 off, 200 on, 200 off, 400 on, 1000 off	DRING 3

The User Agent is responsible for generating distinctive ringing if it receives a SIP Alert Info Header with either of the above specifications.

143.7.3.2 Normal Call Termination Failure

If the CS2000 is attempting to terminate to a SIP line that the CS2000 has determined to be “network idle”, but the termination fails for any of the following reasons:

- User Agent not registered
- User Agent registered, but not responding
- User Agent registered, User Agent responds with busy indication (e.g. Do Not Disturb, or currently in dialing state),

the CS2000 will not offer the calling party the Special Delivery Service (SDS) busy service to activate ACB. The calling party will receive busy tone.

143.7.3.3 ACBAR Recall Notification Failure

If the CS2000 attempts to recall notify a SIP ACBAR subscriber, and that recall attempt fails due to any of the following:

- User Agent not registered
- User Agent registered, but not responding
- User Agent registered, User Agent responds with any response other than a “100 Trying” or “180 Ringing”, (e.g.busy indication due to Do Not Disturb, or currently in dialing state),

the CS2000 will check if the maximum number of recall notifications have been applied to the subscriber for the ACBAR request. If the maximum number of notifications have been applied for that request, the CS2000 will treat the request the same as any other request that has exhausted the recall applications, and terminate the ACBAR request. Otherwise the CS2000 will start the T2 timer, and upon timer expiration, will start the recall notification process again.

143.7.3.4 ACBAR Call Setup Failure

If the SIP ACBAR subscriber has answered the recall notification, and the CS2000 is attempting to setup the call to the destination line (using the REFER method), but the Call Setup request fails due to any of the following:

- User Agent not registered
- User Agent registered, but not responding
- User Agent registered, User Agent responds with anything other than a "202 Accepted" or "NOTIFY:Terminated" (e.g a busy/reject indication)

the CS2000 will check if the maximum number of recall notifications have been applied to the subscriber for the ACBAR request. If the maximum number of notifications have been applied for that request, the CS2000 will treat the request the same as any other request that has exhausted the recall applications and terminate the ACBAR request. Otherwise the CS2000 will start the T2 timer, and upon timer expiration, will start the recall notification process again.

143.7.3.5 ACB/AR Call Termination Failure

If the CS2000 is attempting to terminate to a SIP line because of an ACBAR request using Immediate processing, and the CS2000 has determined that SIP line to be "network idle", but the termination fails for any of the following reasons:

- User Agent not registered
- User Agent registered, but not responding
- User Agent registered, User Agent responds with busy indication (e.g. Do Not Disturb, or currently in dialing state),

the CS2000 will not offer the calling party the Special Delivery Service (SDS) busy service to activate ACB. The calling party will receive busy tone, and the request will be considered completed.

143.7.3.6 User Agent Consultative Transfer (REFER) Attempts Using ACB/AR Vertical Service Codes

If a SIP ACBAR User attempts to transfer a call using a User Agent Consult/ Transfer Capability, where the transfer-to DN dialed is an ACB/AR Vertical Service Code, the ACB/AR service will operate normally on the consult session of the SIP ACBAR User Agent.

For ACB, the number in the SIP User's outgoing call memory will be used as the transfer-to DN. If the transfer-to station is determined to be network idle by the ACB service, the consult session will be setup immediately. If the transfer-to station is determined to be network busy by the ACB service, the SIP ACBAR User Agent will receive the ACB confirmation treatment on the consult session. If the SIP ACBAR User attempted the transfer function (i.e. REFER) prior to or during the confirmation treatment, the transferred party will receive the ACB confirmation treatment. When both the SIP ACBAR User Agent and the transfer-to station are both idle, the SIP ACBAR User Agent will receive the recall notification.

For AR, the number in the SIP User's incoming call memory will be used as the transfer-to DN. If AR 2-level activation is in effect, the SIP ACBAR User Agent will receive the AR 2-level activation announcements on the consult session. If AR 1-level activation is in effect, or the SIP ACBAR User enters the acceptance digit for 2-level activation, and the transfer-to station is determined to be network idle by the AR service, the consult session will be setup immediately. If the transfer-to station is determined to be network busy by the AR service, the SIP ACBAR User Agent will receive the AR confirmation treatment. If the SIP ACBAR User attempted the transfer function (i.e. REFER) prior to or during two-level announcements, the transferred party will receive the AR two-level announcement and will be able to enter the acceptance digit. If the SIP ACBAR User attempted the transfer function (i.e. REFER) prior to or during the confirmation treatment, the transferred party will receive the confirmation treatment.When both the SIP ACBAR User Agent and the transfer-to station are both idle, the SIP ACBAR User Agent will receive the recall notification.

143.7.3.7 ACBAR Edge Condition Interaction Table

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Nodal and Internodal Activation using Immediate Processing Call Setup	IDLE	Not Registered or Registered but not responding	A is any line, B is SIP Line. A activates ACBAR to B. CS2000 attempts call setup with Immediate processing.	If the terminator becomes busy after the initial query but before call setup, the ACBAR user receives busy tone and the request is considered complete.	SIP ACBAR User receives busy tone and the request is considered complete.
Nodal and Internodal Delayed Processing Call Setup	IDLE	Not Registered or Registered but not responding	A is any line, B is SIP Line. A activates ACBAR to B. B is initially busy. B is queued on. B goes idle. A receives recall notification ringing, A answers recall. B loses network connectivity before CS2000 attempts call setup.	If the terminator becomes busy after the final busy/idle query but before call setup, the ACBAR user receives busy tone and the request is considered complete	SIP ACBAR User receives busy tone and the request is considered complete.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Nodal and Internodal Activation using Immediate Processing Call Setup	IDLE	BUSY Dialing	A is any line, B is SIP Line. A activates ACBAR to B. CS2000 attempts call setup with Immediate processing. B is offhook dialing, User Agent responds with 486 BUSY.	If the terminator becomes busy after the initial query but before call setup, the ACBAR user receives busy tone and the request is considered complete.	SIP ACBAR User receives busy tone and the request is considered complete.
Nodal and Internodal Delayed Processing Call Setup	IDLE	BUSY Dialing	A is any line, B is SIP Line. A activates ACBAR to B. B is initially busy. B is queued on. B goes idle. A receives recall notification ringing, A answers recall. B goes offhook and begins dialling before CS2000 attempts call setup.	If the terminator becomes busy after the final busy/idle query but before call setup, the ACBAR user receives busy tone and the request is considered complete	SIP ACBAR User receives busy tone and the request is considered complete.
Nodal and Internodal Activation using Immediate Processing Call Setup	IDLE	BUSY (User Agent Do Not Disturb)	A is any line, B is SIP Line. A activates ACBAR to B. CS2000 attempts call setup with Immediate processing. B has User Agent Do Not Disturb activated. User Agent responds with 486 BUSY.	1) If the terminator has DND activated, the CS2000 will mark the response to the initial query with denied termination, which results in long term denial to the ACBAR User 2) If the terminator activates DND after the initial query but before call setup, the ACBAR User receives busy tone (or DND treatment) and the request is considered complete.	SIP ACBAR User receives busy tone and the request is considered complete.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Nodal and Internodal Delayed Processing Call Setup	IDLE	BUSY (User Agent Do Not Disturb)	A is any line, B is SIP Line. A activates ACBAR to B. B is initially busy. B is queued on. B activates User Agent Do Not Disturb. B goes idle. A receives recall notification ringing, A answers recall. CS2000 attempts call setup. User Agent responds with 486 BUSY.	If the terminator activates DND during busy monitoring, the ACBAR User receives busy tone (or DND treatment) on the subsequent call setup and the request is considered complete.	SIP ACBAR User receives busy tone and the request is considered complete.
Nodal and Internodal Activation using Immediate Processing Call Setup	IDLE	Forwarded (User Agent Call Forwarding Active)	A is any line, B is SIP Line. A activates ACBAR to B. CS2000 attempts call setup with Immediate processing. B has User Agent Call Forwarding activated. User Agent responds with 302 Redirect.	1) If the terminator has CFV active or SCF active for the ACBAR User's number during the initial query process, the ACBAR User will receive short term denial annc. 2)If the terminator activates call forwarding after the initial query, but before the call setup, then on call setup, Call Forwarding procedures will take precedence, that is, the "ACBAR call setup" call will be forwarded to the remote station.	ACBAR Call Setup attempt from SIP ACBAR User to 'B' will be forwarded to the remote station.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Nodal and Internodal Delayed Processing Call Setup	IDLE	Forwarded (User Agent Call Forwarding Active)	A is any line, B is SIP Line. A activates ACBAR to B. B is initially busy. B is queued on. B has User Agent Call Forwarding activated. B goes idle. A receives recall notification ringing, A answers recall. CS2000 attempts call setup. User Agent responds with 302 Redirect.	If the terminator activates call forwarding during busy monitoring then on the subsequent call setup, Call Forwarding procedures will take precedence, that is, the "ACBAR call setup" call will be forwarded to the remote station.	ACBAR Call Setup attempt from SIP ACBAR User to B will be forwarded to the remote station.
Nodal and Internodal Activation using Immediate Processing Call Setup	IDLE	User Agent SCRJ active or SCA active (resulting in rejection treatment)	A is any line, B is SIP line. A activates ACBAR to B. CS2000 attempts call setup. User Agent responds with 3xx redirect response, or 4xx busy response or connects to rejection announcement, depending on rejection treatment configuration	If the terminator has SCRJ active for the ACBAR User's DN during the initial query process, a call to the terminator will be set up immediately, resulting in the ACBAR User receiving rejection treatment.	SIP ACBAR User receives rejection treatment. This may be busy tone for 4xx response, or forwarding for 3xx response, or rejection announcement depending on rejection treatment configuration

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Nodal and Internodal Delayed Processing Call Setup	IDLE	User Agent SCRJ active or SCA active (resulting in rejection treatment)	A is any line, B is SIP Line. A activates ACBAR to B. B is initially busy. B is queued on. B has User Agent SCRJ or SCA activated. B goes idle. A receives recall notification ringing, A answers recall. CS2000 attempts call setup. SIP User Agent responds with 3xx redirect response, or 4xx busy response or connects to rejection announcement, depending on rejection treatment configuration	If the terminator activates SCRJ or SCA during busy monitoring then on the subsequent call setup, the Ragor will receive rejection treatment.	SIP ACBAR User receives rejection treatment. This may be busy tone for 4xx response, or forwarding for 3xx response, or rejection announcement depending on rejection treatment configuration
Notification Recall Ringing	IDLE	Not Registered or Registered but not responding	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A loses connectivity during busy monitoring. B goes idle, and the CS2000 attempts recall ring notification to A.	If the ACBAR User goes offhook just prior to recall ringing notification, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again.	If no response is received from the SIP User Agent on recall notification attempt, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Notification Recall Ringing	IDLE	BUSY	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A goes offhook and starts dialing. B goes idle, and the CS2000 attempts recall ring notification to A. A's User Agent responds with 4xx BUSY.	If the ACBAR User goes offhook just prior to recall ringing notification, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again.	If 4xx BUSY response is received for the recall notification attempt, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again
Notification Recall Ringing	IDLE	BUSY DND (Session Server Advanced Services Do Not Disturb)	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A has Session Server Do Not Disturb active. B goes idle, and the CS2000 attempts recall ring notification to A.	If the ACBAR User has CS2000 DND active at the time of recall notification, the CS2000 will continue with the recall notification and ring the line with ACBAR special ringing.	If the SIP ACBAR User has Session Server DND active at the time of recall notification, then the CS2000 will continue with the recall notification and ring the line with ACBAR special ringing. The notification will not be rejected.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Notification Recall Ringing	IDLE	BUSY (User Agent DND)	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A has User Agent DND active. B goes idle, and the CS2000 attempts recall ring notification to A. A's User Agent responds with 4xx BUSY.	No equivalent scenario.	If 4xx BUSY response is received for the recall notification attempt, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again
Notification Recall Ringing	IDLE	Session Server Advanced Services CFW active	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A has Session Server CFW active. B goes idle, and the CS2000 attempts recall ring notification to A.	If the ACBAR User has CS2000 DND active at the time of recall notification, the CS2000 will continue with the recall notification and ring the line with ACBAR special ringing.	If the SIP ACBAR User has Session Server CFW active at the time of recall notification, then the CS2000 will continue with the recall notification and ring the line with ACBAR special ringing. The notification will not be forwarded.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Notification Recall Ringing	IDLE	User Agent CFW active	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. A has User Agent CFW active. B goes idle, and the CS2000 attempts recall ring notification to A. A's User Agent responds with 3xx REDIRECT	No equivalent scenario.	If 3xx REDIRECT response is received for the recall notification attempt, the redirect attempt will not be honored. If the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again
Notification Recall Ringing	IDLE	Session Server Advanced Services Call Screening (SCRJ) active	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. B is in A's Session Server SCRJ list. B goes idle, and the CS2000 attempts recall ring notification to A.	If the ACBAR User has CS2000 SCRJ active at the time of recall notification, and the terminator's DN is in the SCRJ list, the CS200 will continue with the recall notification and ring the line with ACBAR special ringing.	If the SIP ACBAR User has Session Server SCRJ active, with the terminator's DN on the SCRJ list, at the time of recall notification, then the CS2000 will continue with the recall notification and ring the line with ACBAR special ringing. The notification will not be rejected.

Table 2 ACBAR Edge Condition Interaction Scenario's

ACBAR Phase	ACBAR User Agent Network Line State	ACBAR User Agent Edge Condition	Description: A = ACBAR User B = Terminator	CS2000 non-SIP Line ACBAR User Equivalent	CS2000 SIP Line ACBAR User Result
Notification Recall Ringing	IDLE	User Agent Call Screening (SCRJ) active	A is SIP line, B is any line. A activates ACBAR to B. B is busy and is queued on. B is in A's SCRJ list on A's User Agent. B goes idle, and the CS2000 attempts recall ring notification to A. A's User Agent responds with 3xx redirect response, or 4xx busy response or connects to rejection announcement, depending on rejection treatment configuration	No equivalent scenario.	If 3xx REDIRECT response is received for the recall notification attempt, the redirect will not be honored.If a 3xx or 4xx BUSY response is received for the recall notification attempt, then if the maximum number of recall notification applications has been attempted, the request is considered complete. Otherwise, timer T2 is started, and on T2 expiry, recall notification is attempted again

144: Functional Description (FN) A00012321

144.1 Feature name and Feature ID

A00012321 - SIP Services: Long Distance Alerting (LDA)

144.2 Description

This feature integrates the LDA feature with SIP Lines. The LDA feature provides distinctive ringing patterns for calls determined to be long distance. Provisioning LDA has not been impacted, follow the existing LDA guidelines to configure LDA.

The following table shows the Nortel recommended cadences and SIP Alert Info Header for each of the configurable tones on the DMS.

Table 1 CM Ring Char to SIP Alert Info mapping

LDA RING_PATTERN (table OFCENG)	SIP Alert Info Hdr	DMS Ring Code	NA Cadence (ms - 6 sec cycle)	UK & AUS Cadence (ms - 3 sec cycle)
LONG	http://127.0.0.1/nortel/standard_ring	0	2000 on, 4000 off	400 on, 200 off, 400 on, 2000 off
LONG_LONG	http://127.0.0.1/nortel/dst_ring_5	3	1500 on, 500 off, 1500 on, 2500 off	600 on, 2400 off
LONG_SHORT	http://127.0.0.1/nortel/dst_ring_6	4	1500 on, 500 off, 500 on, 3500 off	200 off, 800 on, 200 off, 200 on, 200 off, 400 on, 1000 off
LONG_SHORT_SHORT	http://127.0.0.1/nortel/dst_ring_7	5	1500 on, 500 off, 500 on, 500 off, 500 on, 2500 off	400 on, 800 off, 200 on, 200 off, 400 on 200 off, 200 on, 200 off 400 on
LONG_SHORT_MEDIUM	http://127.0.0.1/nortel/dst_ring_8	6	1500 on, 500 off, 500 on, 500 off, 1000 on, 2000 off	unused
MEDIUM_MEDIUM	http://127.0.0.1/nortel/dst_ring_1	C	800 on, 400 off, 800 on, 4000 off	600 on, 400 off, 600 on, 1400 off

Table 1 CM Ring Char to SIP Alert Info mapping

LDA RING_PATTERN (table OFCENG)	SIP Alert Info Hdr	DMS Ring Code	NA Cadence (ms - 6 sec cycle)	UK & AUS Cadence (ms - 3 sec cycle)
SHORT_SHORT_MEDIUM	http://127.0.0.1/nortel/dst_ring_2	D	400 on, 200 off, 400 on, 200 off, 800 on, 4000 off	200 on, 200 off, 200 on, 400 off, 600 on, 1400 off
SHORT_MEDIUM_SHORT	http://127.0.0.1/nortel/dst_ring_3	E	300 on, 200 off, 1000 on, 200 off, 300 on, 4000 off	200 on, 200 off, 600 on, 200 off, 200 on, 1600 off

The SIP client is responsible for generating call wait tones if it receives a SIP Alert Info Header while a call is in progress. If SIP client receives an alert-info header not listed in this table then standard_ring should be assumed by the client device:

SIP Alert Info Hdr	NA Cadence (ms - 6 sec cycle)
http://127.0.0.1/nortel/standard_ring	300 on
http://127.0.0.1/nortel/dst_ring_1	100 on, 100 off, 100 on
http://127.0.0.1/nortel/dst_ring_2	100 on, 100 off, 100 on, 100 off, 100 on
http://127.0.0.1/nortel/dst_ring_3	100 on, 100 off, 300 on, 100 off, 100 on

144.3 Hardware Requirements or Dependencies

Any SIP client supported on CS2000.

144.4 Software Requirements or Dependencies

none

144.5 Limitations and restrictions

The tones are limited to the set of tones listed in the following table.

144.8 Glossary

Term	Description

145: Functional Description (FN) A00012322

145.1 Feature name and Feature ID

A00012322 - Session Initiation Protocol (SIP) Services - Busy Line Verification (BLV)

145.2 Description

This activity extends the CS2000 End Office (EO) switch's BLV and Barge In (BI) capability to support SIP Dynamic Packet Lines (DPL). BLV provides a Public Switch Telephone Network (PSTN) Operator with the ability to verify if a line is in an idle or busy state. Utilizing the BLV connection, the PSTN operator may proceed to perform an emergency barge-in of a busy line if required. To establish a BLV connection, an incoming call is initiated by the Operator from Traffic Operator Position System (TOPS) Access Tandem (AT) to the EO. The EO bridges the Operator to the line to be verified. A scrambler circuit is inserted at the TOPS AT to ensure privacy during BLV. The Operator can choose to move to a BI connection by stopping the voice scrambling, at which time the Operator can engage in a conversation with the BLV line. The EO has no knowledge a BI connection has been established as no additional signaling is sent to the EO. However, the line hears an intermittent Operator presence tone every 10 seconds while the BI connection exists. This tone is sent inband from the TOPS AT. The Operator makes a determination of whether the line is in an idle or busy state by listening for scrambled tones or speech. If no tone or speech is detected, the Operator may conclude the line is in an idle state and/or move to a BI connection. If scrambled tones or speech is detected, the Operator may conclude the line is in an idle or busy state based on the nature of the tones and/or move to a BI connection.

In the EO, a BLV call is originated on an Operator (OP) trunk group that can be dedicated to operator verification or can be a combined toll completing/ verification trunk group. With a dedicated verification trunk group, all incoming calls are assumed to be BLV/BI calls. A dedicated verification OP trunk group is configured by datafilling field MODE to "VF" in table TRKGRP. With a combined toll completing/verification trunk group, verification calls must include leading prefix digits to identify the call as BLV/ BI. A combined toll completing/verification OP trunk group is configured by datafilling field MODE to "CV" in table TRKGRP. This activity does not introduce new provisioning requirements for BLV/BI to SIP DPL.

For SIP DPL, H.248 OP trunk groups and OP trunk groups configured on CS2000 legacy peripherals (i.e. XPM, SPM) are supported.

If the Operator initiates a BLV/BI call to a line that is in a busy state, the Operator is bridged into the existing call. With TDM lines, the bridged connection can be established using a Metallic Test Access (MTA) unit or can be established using a conference 3-port circuit. With Voice Over Internet Protocol (VoIP) lines, the bridged connection is always established using a conference circuit. BLV/BI for SIP DPL will also use a conference circuit to bridge the Operator. Therefore, conference circuits must be configured for BLV/BI to SIP DPL. The type of conference circuit required depends on the switch configuration:

- In a hybrid CS2000, where TDM and packet agencies exist, there is an existing restriction that H.248 OP trunks can *not* be used for BLV/BI to a TDM line or to any line involved in a call with at least one TDM agent (line or trunk). This activity is not addressing this restriction. Therefore in a hybrid CS2000, OP trunks for BLV/BI must be configured on an XPM or SPM. In this case, TDM conference ports are always used for BLV/BI and must also be configured.

  In a hybrid CS2000, the OP trunks must be configured on an XPM or SPM.

- In a packet only CS2000, an H.248 OP trunk will be configured as all the agencies are packet based. In this case, packet conference ports are used for BLV/BI.

  Only Audio Media Server (AMS) conference ports will be supported for BLV/BI to SIP DPL. The Universal Audio Server (UAS) is not supported.

The behavior of SIP DPL differs slightly from TDM/VoIP lines. SIP DPL use the SIP application layer control (signaling) protocol to create, modify and terminate sessions. A SIP DPL may have multiple sessions active at any given time. BLV/BI support for SIP DPL needs to take these SIP DPL specific behaviors/capabilities into consideration. Therefore, the BLV/BI capability provided by this activity for SIP DPL differs from the existing BLV/BI capability for TDM/VoIP lines. The following sections describe the new BLV/BI capability provided by this activity for SIP DPL.

145.2.1 BLV/BI Capability for Idle SIP DPL

The existing BLV/BI capability for TDM/VoIP lines establishes a bridge-tap connection to the TDM/VoIP line when in an idle state (i.e. onhook). The Operator listens for tones and/or speech while bridged. If the TDM/VoIP line goes offhook, the subscriber is not permitted to dial a new call. The Operator may choose to advance from a BLV connection to a BI connection by stopping the voice scrambling and then initiate a conversation with the subscriber.

With SIP DPL, it is not possible to establish this type of bridge-tap connection and a different approach is required. Rather than a bridge-tap connection, if the SIP DPL is determined to be idle, the Operator will be provided silent tone. A

connection will not be established with the SIP DPL. When the Operator disconnects, the OP trunk will be released.

This approach provides a behavior that is very similar to the BLV behavior for idle TDM/VoIP lines. With idle TDM/VoIP lines, the Operator hears silence while bridged and concludes the line is idle based on the silence. By providing silent tone for SIP DPL, the Operator will also be able to determine the SIP DPL is idle by listening. Impacts to the Operator's practices and procedures for BLV should be minimal (if any).

Note that with BLV to idle TDM/VoIP lines, there is a low runner scenario where the subscriber could go offhook during a BLV connection. The Operator could choose to advance to a BI connection at this time. Due to the nature of SIP lines, this capability is not provided for SIP DPL.

145.2.2 BLV/BI Capability for Busy SIP DPL

The existing BLV/BI capability for TDM/VoIP lines bridges the Operator to the busy call using a conference circuit or MTA (for TDM lines only). The busy call must meet a set of criteria before the Operator is bridged. If the bridging criteria is not met, busy line treatment is provided to the Operator.

BLV/BI to a busy SIP DPL will behave similar to TDM/VoIP lines with one key difference. A SIP DPL can have one or more sessions established when BLV/BI occurs. If only one session exists, that session will be checked to see if it meets the bridging criteria. If multiple sessions exist, the list of sessions will be searched to find a session that meets the bridging criteria. The bridging criteria for BLV/BI is the same criteria used for TDM/VoIP lines, with two exceptions:

- SIP DPL sessions can be in either an active or held state. The bridging criteria checking for SIP DPL will include a new criteria for an *active* session. BLV/BI will not bridge the Operator to a session that is held. The Operator will be bridged to a session in the *active* state only.

  It is possible the Operator will be bridged to an active session which is subsequently held. In this case, the BLV/BI connection will be bridged to a held connection. If the session becomes active again, the BLV/BI connection will persist.

- The three-way calling service is provided by the SIP DPL and is no longer a CS2000 Core based service. For SIP DPL, the Operator can be bridged to a three-way call if this service is being provided by the SIP DPL.

In the event a session can not be found that passes the bridging criteria, the Operator will be provided busy line treatment. This is consistent with the BLV/BI capability for TDM/VoIP lines, which provides busy line treatment if the call is not suitable for bridging. Note that a maximum of 10 SIP DPL sessions will be searched to find a suitable session for bridging.

The existing TDM/VoIP bridging criteria checking that will also be used for SIP DPL consists of, but is not limited to:

- The busy call must be in an answered state.
- No Complex Call Service can be actively running on the busy call.
- The connected party in the busy call cannot be an OP trunk group or Emergency Services (ES) trunk group.
- The busy call does not include an Attendant console.

While the Operator is bridged to the call, any of the parties involved in the call can disconnect. The action taken upon the detection of a disconnect is dependent on which party initiates the disconnect:

- If the Operator disconnects from the bridged connection, the conference circuit is removed and the remaining two parties are bridged back into a 2-party call.
- If the connected party disconnects while the Operator is bridged, the conference circuit is removed and the Operator and SIP DPL are bridged into a 2-party call.
- If the SIP DPL disconnects while the Operator is bridged, the Operator is provided silent tone and the connected party is released.

  This behavior for BLV/BI to a SIP DPL is different than the behavior for BLV/BI to a TDM/VoIP line. With a TDM/VoIP line, the Operator is reconnected to the idle line after the disconnect. The Operator can listen to the connection and determine the line has disconnected. With SIP DPL, the same functional behavior is provided by applying silent tone to the Operator.

145.2.3 BLV/BI Interactions with SIP DPL Maintenance States

With the BLV/BI capability for TDM/VoIP lines, the Operator is provided treatment if the line is in a maintenance state. BLV/BI for SIP DPL is consistent with this approach. If the SIP DPL is in a maintenance state, the Operator is provided treatment. The standard treatment associated with the SIP DPL's state is provided. At this time, the line maintenance states that apply to a SIP DPL include:

System Busy (SB), Man Busy (MB), Offline (INB),

Call Processing Busy Deload (CPD), LCD Busy (LMB)

145.3 Hardware Requirements or Dependencies

TDM and/or AMS conference ports must be configured as described in section "144.2 Description" on page 1430.

145.4 Software Requirements or Dependencies

Not applicable.

145.5 Interactions

145.5.1 CS2000 Core based Service Interactions

This section describes the interaction between BLV/BI and Core based services. These interactions are handled in consistently with BLV/BI to TDM/ VoIP lines. The key service interactions are described below (other service interactions may exist).

- Advanced Intelligent Network (AIN) Terminating Call Model (TCM) and Originating Call Mode (OCM) triggers are bypassed for BLV/BI.
- The Denied Termination (DTM) line option has no impact on BLV/BI calls. The Operator is conferenced to verify a SIP DPL line when the DTM line option is assigned.
- BLV/BI will not bridge to a call that has an active Lawful Intercept connection. Busy Line treatment is provided to the Operator.
- A BLV/BI call is not supported to a SIP DPL that has service suspended via the Suspended Service (SUS) or Plug Up (PLP) line options. Trouble intercept treatment (TRBL) and terminator suspended service (TESS) treatment are provided to the Operator respectively.
- A BLV/BI call is not supported to a SIP DPL that is assigned the No Double Connect (NDC) line option. Busy Line treatment is provided to the Operator.
- BLV/BI calls will not series complete if the SIP DPL has the Series Completion (SCMP) line option assigned. If at least one session exists for the SCMP SIP DPL when the BLV/BI call is received, an attempt will be made to conference the Operator to an existing session as described in section 144.2.2. If the SIP DPL is idle, silent tone is provided to the Operator as described in section 144.2.1.
- For MLH and DLH hunt groups, the BLV/BI call is always attempted on the pilot DN for the hunt group. For DNH and BNN hunt groups, the BLV/ BI call is always attempted on the dialed DN. The BLV/BI request will not hunt.

  If at least one session exists for the SIP DPL when the BLV/BI call is received, an attempt will be made to conference the Operator to an existing session as described in section 144.2.2. If the SIP DPL is idle, silent tone is provided to the Operator as described in section 144.2.1.
- Call forwarding services that *unconditionally* forward the call are not supported for BLV/BI. If a BLV/BI call is requested to a SIP DPL configured with a call forwarding *always* service, the Operator is provided busy line treatment.
- If the SIP DPL is busy with a call forward *busy* feature activated, the BLV/ BI call is not forwarded. Rather, an attempt will be made to conference the Operator to an existing session as described in section 144.2.2.

- When a BLV/BI connection is established to a busy call involving a SIP DPL with the Call Park or Directed Call Park line option, the call park capability is disabled. The SIP DPL can not park the call while the Operator is bridged. Feature action nack (NACK) treatment is provided to the Operator.
- When a BLV/BI connection is established to a busy call involving a SIP DPL with the Call Park or Directed Call Park line option, the call park capability is disabled. The SIP DPL can not park the call while the Operator is bridged. Feature action nack (NACK) treatment is provided to the Operator.
- When a BLV/BI connection is established to a busy call involving a SIP DPL configured with the Account (Acct) Code feature, the Acct Code feature is disabled for Flash Entry. A Flash Entry occurs when the SIP DPL flashes during an active call, dials the Acct Code feature access code followed by the account code, then flashes to re-join the active call. If the active call has a BLV/BI connection established, the Flash Entry is ignored and an IBN110 log is output indicating a BLV connection was in progress. Refer to activity A00012326, Auth/Account Codes support for SIP Lines, for further information on the IBN110 log.
- When a BLV/BI connection is established to a busy call involving a SIP DPL configured with the Authorization (Auth) Code feature, the Auth Code feature is disabled for Flash Entry. A Flash Entry occurs when the SIP DPL flashes during an active call, dials the Auth Code feature access code followed by the auth code, then flashes to re-join the active call. If the active call has a BLV/BI connection established, the Flash Entry is ignored and an IBN110 log is output indicating a BLV connection was in progress. Refer to activity A00012326, Auth/Account Codes support for SIP Lines, for further information on the IBN110 log.
- When a BLV/BI connection is established to a busy call involving a SIP DPL, the Malicious Call Hold (MCH) feature is disabled. The SIP DPL can not activate the MCH feature. Feature action nack (NACK) treatment is provided to the Operator.
- BLV/BI requests to SIP DPL in a call pickup group will bridge the Operator to the SIP DPL's busy call, even if that call was established through the call pickup service. The following call pickup services are supported for SIP DPL:

  — Call Pickup (CPU)

  — Directed Call Pickup (DCPU)

  — Night Service Trunk Answer From Any Station (TAFAS)

  — Directed Call Pickup with Barge-In (DCBI)

  With DCBI, when a barge-in connection is established involving a SIP DPL, there are two active sessions. Both sessions are considered eligible

for BLV and will be included in the criteria checking search (as described in “144.2.2 BLV/BI Capability for Busy SIP DPL” on page 1432.

145.5.2 SIP DPL (SIP Client) Service Interactions

This section describes the interaction between BLV/BI and SIP DPL (i.e. SIP Client) based services.

- The SIP DPL Blind Transfer and Consult Transfer capability is denied if any call leg involved in the transfer is a BLV/BI call. This restriction applies if the Operator is verifying the SIP DPL or the connected party in either call leg. The only exception is if the Operator is verifying a connected TDM line using an MTA, in which case the transfer request is not denied. Examples include, but are not limited to:

  — SIP DPL is involved in a two-party call with a TDM line. A BLV/BI call to the SIP DPL results in the Operator being conferenced to the call using a conference port. The SIP DPL attempts to blind transfer the TDM line.

  — SIP DPL is involved in a two-party call with a TDM line. A BLV/BI call to the TDM results in the Operator being conferenced to the call using a conference port. The SIP DPL attempts to blind transfer the TDM line.

    If the BLV/BI connection to the TDM line is established using the MTA, the transfer request will not be denied.

  — SIP DPL is involved in two calls. The first call leg is a BLV/BI call. In the second call leg, the SIP DPL is connected to another party. The SIP DPL attempts to consult transfer the other party on the second leg to the Operator.

  — SIP DPL is involved in two calls. In the first call leg, the SIP DPL is connected to another party. The second call leg is a BLV/BI call. The SIP DPL attempts to consult transfer the Operator to the other party in the first call leg.

- With 3WC and 6WC[1] using the Media Application Server (MAS), there is no guarantee a BLV/BI request for a SIP DPL controller will result in a connection with the controller.

  — As each call leg of a 6WC is established by an ONT controller, each call leg becomes suitable for bridging after answer is received. The controller can then place these call legs on hold, leaving them in the conference, while the controller establishes another new call leg. In this case, there is no indication the controller has left the conference. All call legs remain suitable for BLV/BI bridging. If a BLV/BI call is received for the controller while in this state, the Operator will be

[1]The Optical Network Terminal (ONT) uses the MAS for 6WC only. The PC Client uses the MAS for all conference configurations (e.g. 3WC, 6WC).

bridged to one of the call legs that is on hold in the conference even though the controller is not actively connected.

– The same interaction applies to a 3WC or a 6WC established by a PC Client controller.

— When the controller of a 6WC is an ONT and the controller disconnects, the conference is taken down.

– If a BLV/BI connection was established to the controller, the Operator will receive silent tone when the controller disconnects.

– If a BLV/BI connection was established to one of the other parties in the conference (i.e. other than the controller), the BLV/BI connection will persist after the controller disconnects.

— When the controller of a 3WC or 6WC is a PC Client and the controller disconnects, the conference remains active until all parties involved in the conference disconnect. Although the controller has disconnected, the controller still has active call appearances for each call leg of the conference.

– If a BLV/BI connection was established to the controller before the controller disconnected, the Operator will remain connected to the conference even though the controller has disconnected.

– If a BLV/BI connection was established to the controller after the controller disconnected, the Operator will be connected to one of the call legs even though the controller had previously disconnected.

145.6 Limitations and restrictions

The following limitations and restrictions apply to BLV/BI for SIP DPL:

- Only H.248 OP trunks and OP trunks configured on CS2000 legacy peripherals (i.e. XPM, SPM) are supported for BLV/BI to SIP DPL.
- In a hybrid CS2000, with TDM and packet agencies, there is an existing restriction that H.248 OP trunks can *not* be used for BLV/BI to a TDM line or to any line involved in a call with at least one TDM agent (line or trunk). This activity is not addressing this restriction. Therefore in a hybrid CS2000 with SIP DPL, the OP trunks must be configured on a CS2000 legacy peripheral (i.e. XPM, SPM).
  — H.248 OP trunks for BLV/BI are not supported in a hybrid CS2000. The OP trunks must be configured on an XPM or SPM.
  — TDM conference ports must be configured in the hybrid switch for BLV/BI.
- In a packet based (non-hybrid) CS2000 switch, packet conference ports must be configured for BLV/BI.

Only AMS conference ports are supported for BLV/BI. The Universal Audio Server (UAS) is not supported.

- A BLV/BI call to a busy SIP DPL searches for a suitable session to bridge. A maximum of 10 sessions will be searched to find a suitable session.
- If a BLV/BI request conferences into a multi-media session for a SIP DPL, the session will drop to a voice only connection. If the Operator subsequently drops out of the call and the SIP DPL is reconnected into a 2-party call with the other party, the multi-media capability is re-negotiated.
- When a conference circuit is inserted, the session's remote held status is not conveyed through the conference resource. As a result, the session's remote held status is not conveyed while a BLV/BI connection is active.

  This scenario can occur during a race condition where a BLV connection is established at the same time a remote hold is applied. This scenario can also occur if the session is placed on hold after the BLV/BI connection is established.
- Calls on H.248 Per-Trunk Signaling (PTS) trunks receiving a tone (e.g. treatment tone) are taken down over a Core warm restart. This behavior also applies to BLV/BI calls when the H.248 OP trunk is provided silent tone (i.e. when the BLV line is idle).
- During a Core maintenance cold or reload swact, BLV/BI calls are among those calls cleared in the Core. This includes the BLV/BI call leg on the OP trunk and the original 2-party call that was established between the BLV line and the connected party. Additionally, during the swact, the Gateway Controller (GWC) marks all call processing busy (CPB) calls (including BLV/BI calls) to be taken down when the next internal or external event occurs. It is possible an internal event may occur during the swact resulting in an immediate tear down of the associated CPB call in the GWC. But an internal event may not occur, which can result in the BLV/BI call and original 2-party call being cleared in the Core but persist in the GWC. However, these calls will persist in the GWC no longer than five minutes following the swact. After five minutes, an audit in the GWC will clear the calls. Note that whether an internal event occurs during the swact is unpredictable.
- BLV/BI is not supported to a busy call that involves a Multiple Appearance Directory Number (MADN) SIP DPL. The Operator is provided busy line treatment if either the BLV line or the connected party is a MADN SIP DPL.

146: Functional Description (FN) A00012323

146.1 Feature name and Feature ID

Feature ID: A00012323

Session Initiation Protocol (SIP) Services:
- Directed Call Pickup with Barge-in (DCBI)
- Directed Call Pickup Barge-in Exempt (DCBX)

146.2 Description

This activity extends the CS2000 End Office (EO) switch's DCBI and DCBX capability to support Dynamic Packet Lines (DPL) using the SIP functional protocol.

Directed Call Pickup - Barge In (DCBI) permits an IBN station to pick up a ringing intragroup call without for a line within the same customer group. If the called station answers the call before the instigating party completes the call pickup sequence, the instigating party can barge in to the answered call, resulting in a conference state.

An optional warning tone can be applied to both parties of the existing call before the activating station is barged-in. Application of this tone is a customer group option in table CUSTSTN. The DCBI tone consists of 440 Hz at -13dbm.

A called station with directed call pickup barge-in exempt (DCBX) can block any attempts by another station with DCBI to barge in (the caller hears reorder tone).

A called station with directed call pickup exempt (DCPX) can block any attempts by another station to either barge in or pick up the call (the caller hears reorder tone).

Dynamic Packet Line (DPL) Support:

> ***Note:*** In this document, DPL lines are synonymous with Session Initiation Protocol User Agents (SIP UAs).

For the purposes of further discussion into the individual behaviors, the following terms are used:
- A - the calling party of the original call (originator)
- B - the barge-in target (BI target)
- C - the barge-in instigator (BI instigator)

146.2.1 Barge-in target is not DPL

If the BI target is not DPL, then the existing method of using CS2000 controlled 3 port conference circuits will be used. The type of conference circuit chosen, whether Audiocodes Media Server (AMS) or Maintenance Trunk Module (MTM) based, will depend on the agent type of the BI instigator. For SIP DPL lines, the preference will be AMS if available. The barge-in tone, if provisioned against the customer group in table CUSTSTN (DCBITONE) will be applied to the conference circuit.

All DCBI behavior will be consistent with TDM and packet agents, including the limitation that the BI target will not be considered the conference controller when the calls have reached a conferenced state. Flashes from the BI target will be ignored, and should any party disconnect, the call will collapse into a two party call between the remaining agents.

146.2.2 Bargein target is DPL

146.2.2.1 DCBI Behavior

If the barge-in target is a DPL line, the DCBI behavior is extended to make use of the Session Initiation Protocol's (SIP's) ability to request a new INVITE message to the BI target, with a JOIN header to remotely join this new call to the existing BI target call using the SIP A's conferencing abilities. Once the INVITE/JOIN request has been sent, the CS2000 will view the resulting topology as two independent active calls on two separate DPL instances.

When the BI target is DPL, it will be up to the SIP UA to either handle or reject the request. All subsequent messages following the INVITE/JOIN will be handled by standard call processing.

Once the barge-in request has been completed and a remote conference has been formed, the DPL BI target will become the conference controller. The SIP UA will then be in charge of the topology of the call, and can either:

- Drop one leg of the conference, either by refusing the request or by handling a flash request.
- Request that the originator be REFER'd to the instigator.

Barge-in Tone:

Barge-in tone must be provided by the SIP UA. The CS2000 will not.

> ***Note:*** Due to the nature of barge-in on SIP UAs that support remote conferencing, the application of the barge-in warning tone is not under the control of the CS2000. According to GR-590, the barge-in warning tone is only required to be played to the user being barged in on, which differs from the legacy DMS implementation of the DCBI service which played the tone to both users on the original call. The implementation of barge-in

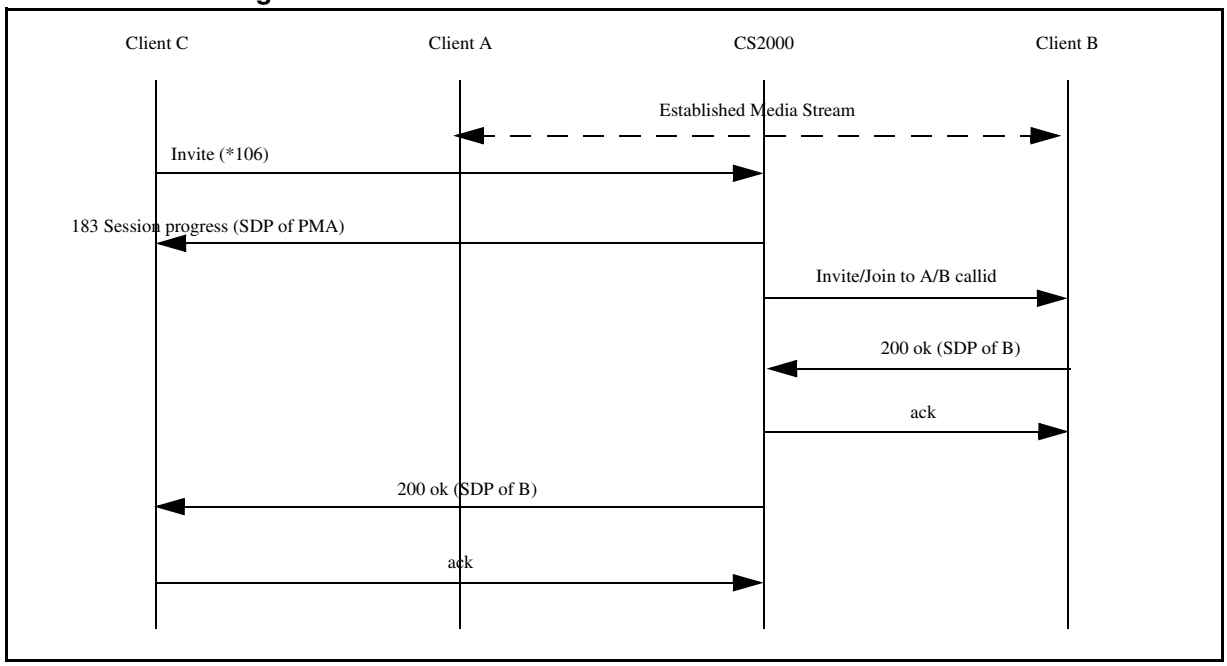
in the SIP UA is out of the control of the CS2000 and is likely to be more GR compliant than is the legacy DMS service.

Remote Conference Transcoding:

It will be a function of the SIP UA to handle SDP re-negotiation in the event that the transcoding (code and packetization rate) in use for existing call are incompatible with the SDP of the BI instigator. The customer should ensure that in all cases, there is a common transcoding algorithm that can apply to all parties.

146.2.2.2 DCBI Message Sequence Chart

Figure 1 Invite/Join MSC



146.2.3 DCPX/DCBX

If either Directed Call Pickup Exempt (DCPX) or Directed Call Pickup Barge-in Exempt (DCBX) is assigned to the BI target, the bargein attempt will not be allowed. The instigator will receive NACK treatment.

146.2.4 Provisioning

DCBI is provisioned in the core against the instigator's line. Once provisioned, DCBI can be used to either pick up or barge in on calls within the same customer group. To block DCBI, either DCPX or DCBX must be assigned to the target line.

146.3 Hardware Requirements or Dependencies

None.

146.4 Software Requirements or Dependencies

In order to use the DPL remote conferencing abilities, the SIP User Agent (UA) must support the following SIP messages:

- The INVITE message with a JOIN header as specified in the IETF Join RFC3911.

  - required in order to remotely join the instigating party to the existing call
- The REFER message as specified in the IETF Refer specification RFC3515.
- The ability to provision and apply a barge-in tone prior to joining the instigator to the existing call (if desired).

146.5 Limitations and restrictions

The following limitations and restrictions apply to DCBI/DCBX for SIP DPL:

- All limitations and restrictions for Directed Call Pickup (non barge-in) for SIP DPL lines as documented in a00012308 are inherited by this activity.
- All TDM DCBI/DCBX limitations and restrictions are inherited by this activity, unless otherwise noted.
- Limitations and restrictions for when the bargein target is SIP DPL:
  - The SIP UA will need to be configured to apply the bargein tone if required. The changing of the CS2000 provisioning of the DCBI warning tone will have no impact on the presence or absence of the tone when barging into a SIP UA agent.
  - Bargein will only be supported for SIP UAs that support the JOIN header in the INVITE message.
  - DCBI barge-in is only supported if there is at most one other active session on the BI target when the DCPU/DCBI VSC is processed. This is consistent with TDM in blocking the DCPU or DCBI of a CWT call, whether ringing or answered.
  - DCBI is not supported unless the SIP DPL BI target is assigned the DPL option with MAX_NUM_CALLS greater than one.
  - It will be up to the SIP UA to renegotiate SDP to address transcoding incompatibilities between the original call and the DCBI instigator when processing the INVITE/JOIN request if required.
  - In order for the bargein target to exit the call and collapse the remaining agents to a 2 party call, that SIP UA must support the REFER message.
  - A FRLS of the bargein target DN will tear down both call legs.
  - The CS2000 will make every attempt to not initiate a bargein session that is on hold, but that could occur in certain race conditions. This

can be avoided if the client rejects the INVITE w/JOIN if an attempt is made to JOIN a session that the client believes to be on hold.

— If the SIP UA does not properly support the JOIN header but does not reject the INVITE with the JOIN header the CS2000 will tear down the call and route the DCBI invoker to treatment upon receipt of an alerting indication in the CS2000. This is to prevent unexpected behavior of the service on non-compliant SIP UAs.

- Limitations and restrictions for when the instigator is SIP DPL:

  — DCBI instigation is allowed only if the instigator has no other calls, either active or held.

146.6 Interactions

146.6.1 Three way calling (3WC)

If the SIP DPL is involved in a 3WC, barge-in is not allowed.

146.6.2 Call Waiting

In TDM, DCBI cannot be used to barge in on a call where call waiting is being applied.

146.6.3 Session Server (SS) Service Interactions

Personal agent based services provided by the Session Server do not apply when a call is being terminated to a SIP DPL line for barge-in.

147: Functional Description (FN) A00012325

147.1 Feature name and Feature ID

A00012325 - SIP Lines: Teen Line

147.2 Description

This activity provides CS2K support for SIP lines for Teen Service. Teen Service refers to the SDN option, which allows multiple DNs to be associated with one line - each such DN has an associated ringing pattern. The SDN option has additional sub-options available on a per-DN basis.

147.3 UA Interactions & Requirements

If the UA is not registered, calls attempting to terminating to it are unaffected by this feature.

If the UA does not respond to an INVITE, calls attempting to terminating to it are unaffected by this feature.

If the UA rejects an INVITE, calls attempting to terminating to it are unaffected by this feature.

The UA used for this feature must support all requirements placed on DPL UA. Additionally, since the UA provides the actual ringing and the call waiting tones, and Teen Line makes use of distinctive ringing patterns and distinctive call waiting tones, there must be a way of informing the UA agent of which ringing pattern/call waiting tone should be used.

The way is the SIP Alert Info header in the SIP INVITE method. The Session Server is responsible for mapping the GCP tone into the proper SIP tone based on the client device (vendor specific tones). The following tables describe the tone definitions and the default mapping, as well as two internal mappings.

The UA is responsible for generating the alerting tone if it receives a SIP Alert Info header in a SIP INVITE method if no call is already in progress.

The UA is responsible for generating call wait tones if it receives a SIP Alert Info header in a SIP INVITE method while a call is already in progress.

Table 1 SDN to SIP Alert Info mapping - ringing

148: Functional Description (FN) A00012326

148.1 Feature name and Feature ID

A00012326 - SIP Lines: Authentication and Authorization

148.2 Description

This activity provides support for Authentication and Authorization account codes for Dynamic Packet Lines (DPL) using SIP. The Account code functionality allows a subscriber to enter a billing number into a Station Message Detail Recording (SMDR) record for charge-back purposes.

An authorization code is a specified set of digits assigned to and used by station end users. These codes can range in length from 2 to 14 digits. When set, the length does not change for the customer group. Authorization codes provide cost control. These codes control access to specified networks. Authorization codes raise or lower the network class of service (NCOS) of a call.

This feature supports Account/ Auth Codes Flash Entry for SIP Lines.

148.3 Hardware Requirements or Dependencies

Not applicable

148.4 Software Requirements or Dependencies

Not applicable

148.5 Limitations and restrictions

The following limitations and restrictions:

- When a call is in progress, and we try to dial Acct/Auth code in a new session, if the client starts a conference call, then the tones provided will be heard in the conference.
- Multiple call appearances are not supported.
- In case the Originator is SIP ONT, the special dialtone received when the originator dials Account/Auth FAC/VSC, is provided by the PMA and not the ONT.
- Account codes can range from 2 to 14 digits in length. The length of the account code is the validation method in the North American and the Canadian market.
- The reset dialing does network if the STARACPT suboption is set toY and the account code is entered voluntarily.

- The STARACPT subfield is set to N for the Asia Pacific CALA markets.
- The account code validation is by content when subfield STARACPT is set to N.
- The log AMAB150 displays a blank space for the asterisk as the valid digit for the voluntary account code.
- The functionality for POTS digit collection applies to the voluntary account code activation only.

148.6 Interactions

A description of the interactions between Acct/Auth codes flash entry and other functionalities appear in the following paragraphs.

- If the invoker of ACCT/AUTH or the connected party is being verified by the Operator, verified by the Operator, the request is denied. ACCT/AUTH is not permitted if an Operator Busy Line Verification (BLV) connection exists.
- In case of analog clients like the ONT where one call is already established and a new session is initiated to enter the FAC followed by the prompt for account/auth code, if the user invokes a client based conference, then the first session would hear the DN prompt and RODR treatment before the second leg is collapsed.

149: Functional Description (FN) A00012385

149.1 Feature name and Feature ID

A00012385 - SIP Lines MADN Support

149.2 Description

The purpose of this feature is to interwork a specific set of Session Initiation Protocol (SIP) clients into IBN/RES network-based Multiple Appearance Directory Number (MADN) Single Call Arrangement (SCA) features.

SIP Line support is providing the following MDN line options, suboptions, and subfeatures:

— SCA - single call arrangement

— SCA Bridging

— PRL - MADN Privacy Release, PRLA and PRLC activation code

— SCA MREL - MADN Release of Bridging

149.3 Hardware Requirements or Dependencies

There are no hardware dependencies required to execute this feature.

149.4 Software Requirements or Dependencies

149.4.1 Feature Activity Dependencies

- A00012223 “SESM: Additional Provisioning for SIP Lines
- A00009528 “Call Pickup on Multimedia Communications Platform MCP 9.0”
- A00012273 “SIP Lines: Call Forward Indication”

149.4.2 Software Dependencies

- Succession release SN09 with drop 2 service set patches.
- GWC load GC091
- Session Server / Manager software load MCP_9.1.0.0

149.4.3 Firmware Dependencies

None

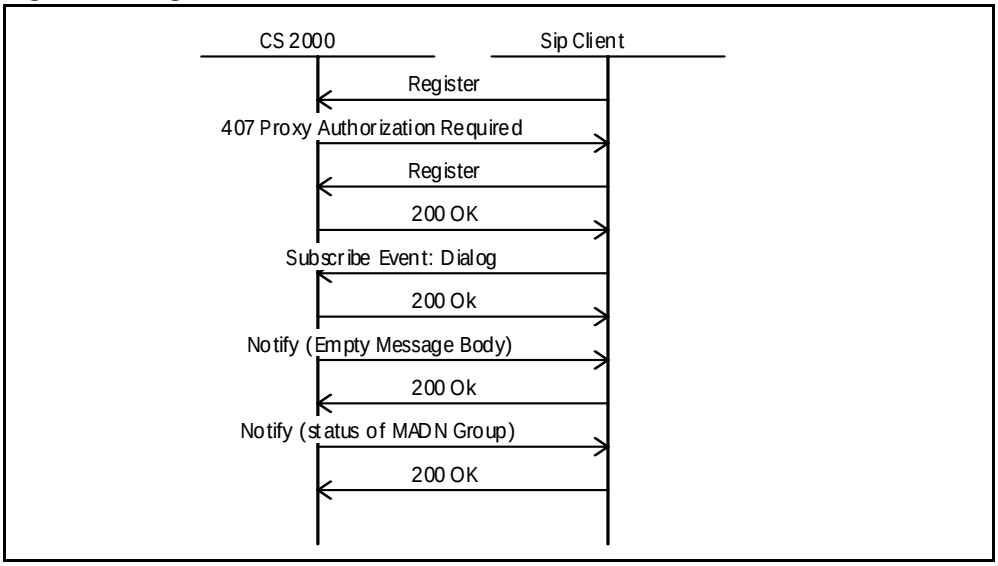
149.4.4 SIP Client Requirements

SIP Clients wishing to supply CS 2000 Network-Based MADN SCA Bridging functionality are expected to be compliant to RFC 3261, RFC 3265 and draft-ietf-sipping-dialog-package-06. The following information is provided so Client vendors will understand the message sequences of special importance.

149.4.4.1 Client Registration/Subscription and the Dialog Event Package

The ONT SIP clients must be provisioned with the MADN Dialog Event Package such that the client will properly register for the events. When a client supporting MADN registers, in addition to sending a SIP Registration to register the contact, it also needs to Subscribe to the Dialog event package. The message sequence is shown below. All of the Register and Subscribe messages should be authenticated by the SS. In the flow below the expectation is that the client is reusing the Proxy Authentication header.

Figure 1 Registration Call Flow



The Subscription to the dialog event should be subscribing to the user's own dialog status. The first Notify sent back will just contain the time out information for the subscription. The ONT should not treat an empty message body as anything other than a Notification of the status of the subscription. It should not cause a state change for the MADN group status. In order to change the group status the client must receive a message body in the Notify. Only two of the states are expected to be reported for the MADN group. If the group is busy the state of Confirmed will be sent. If the group is idle the state will be terminated.

The content type of the message body is that defined in the draft which is: application/dialog-info+xml. The message body for the active state will look like the following:

```
<?xml version="1.0"?>
  <dialog-info xmlns="urn:ietf:params:xml:ns:dialog-info"
               version="0" state="full"
               entity="sip:MADNDN@example.com">
    <dialog id="as7d900as8">
      <state>confirmed</state>
    </dialog>
  </dialog-info>
```

The MADNDN in the above message body example will be replaced with the actual MADN.

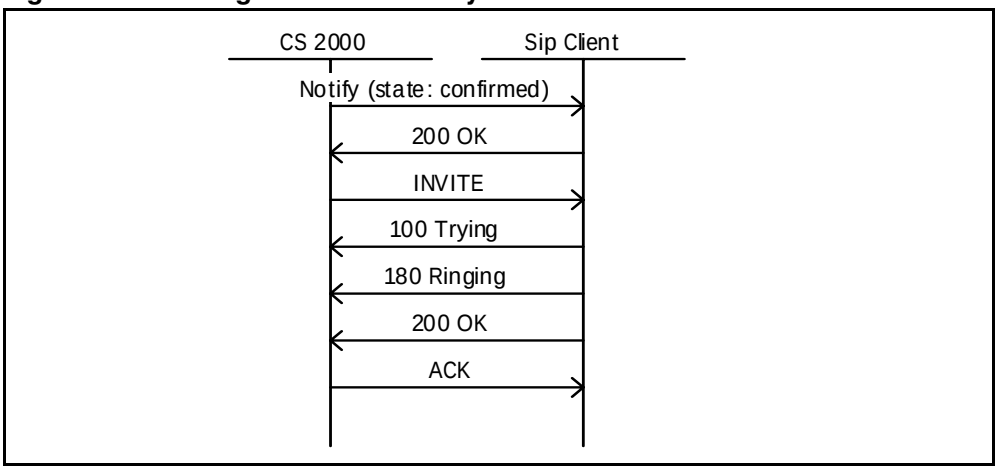
For the idle state the confirmed will be replaced with terminated. If the client has not received any indication of a state change it should assume that the state of the group is idle.

The reason that the state of the group is important is that any member of a MADN SCA group needs to treat an off-hook while the group is active as a bridging request unless a client is currently processing an inbound invite. The bridging request is discussed in section “148.4.4.3 Bridging Requests”

149.4.4.2 Incoming Call Processing

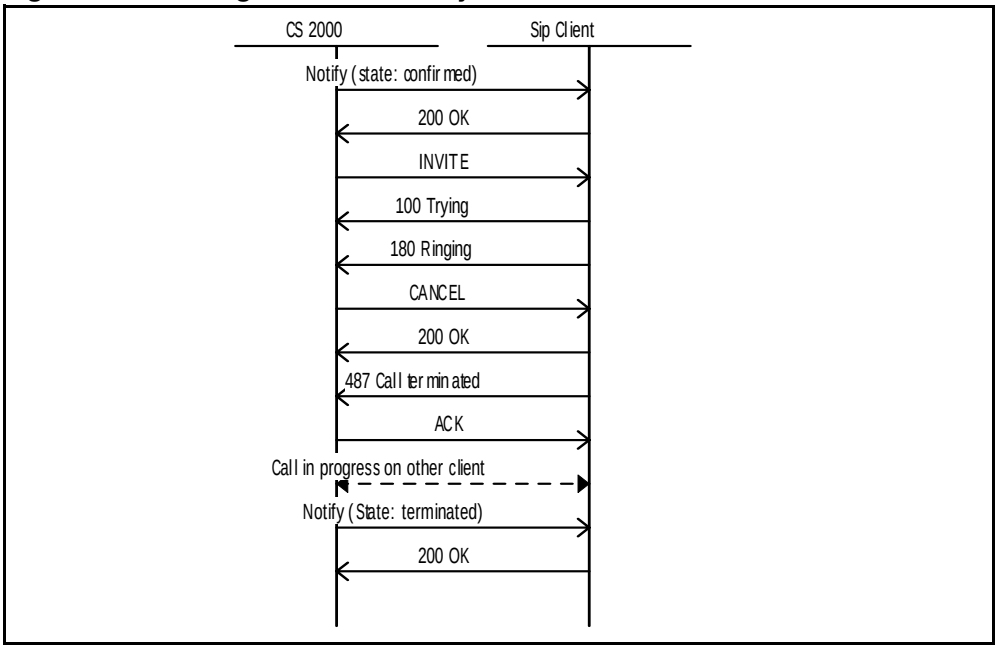
An inbound call to a client should be processed as any normal SIP invite inbound to the client. The state of the MADN group should not cause an inbound INVITE to be treated any differently. The Group will transition to the confirmed state either shortly before the Invite is received or shortly afterwards.

Figure 2 Incoming Call Answered by Client



If the call is answer by another member of the MADN group the call flow will look like any other abandoned call. The group will stay active until the call is released by all members of the MADN group.

Figure 3 Incoming call answered by another client



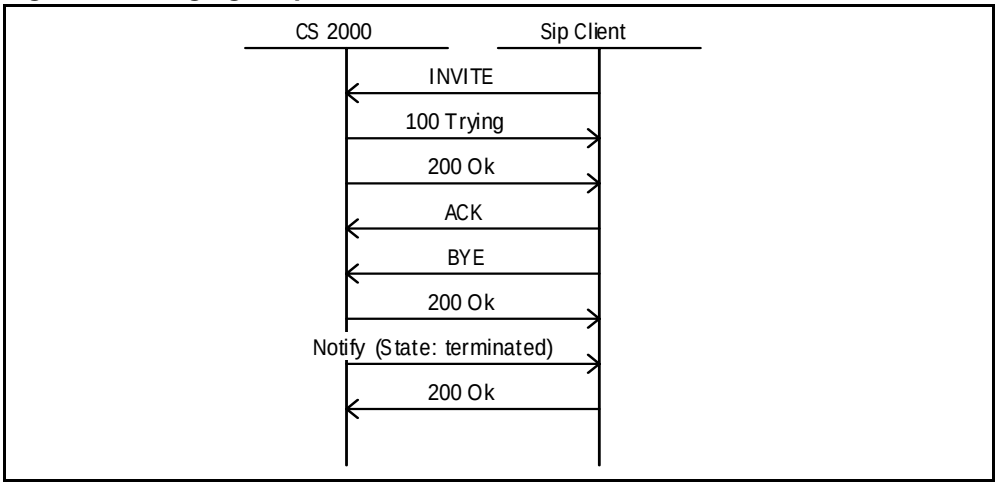
149.4.4.3 Bridging Requests

When a client is Idle but the group is busy and the user takes the handset off-hook the client should initiate an invite immediately without providing dial tone or letting the user input dtmf digits. This invite will be treated as a request to bridge the call into the active call. For this invite request it is recommended that the Invite look like the user is calling themselves. For example if the MADN dn is 555-1212 and the domain for the user is example.com the status line, to and from headers for the call would look like the following:

INVITE sip:5551212@example.com SIP/2.0
To: sip:5551212@example.com
From: sip:5551212@example.com;tag=3149adf0987

The rest of the INVITE would be formatted as any other initial INVITE request from the client. The call will be fast answered, meaning the client will receive a 200 Ok to the INVITE without any other provisional responses with the exception of the 100 trying.

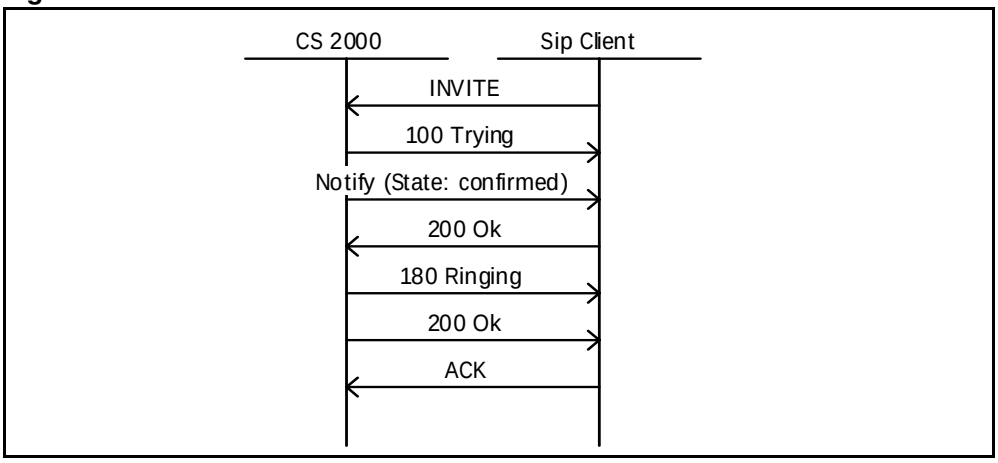
Figure 4 Bridging Request



149.4.4.4 Outbound Call

The normal outbound call case is when an idle client in an idle group sends an INVITE out. In this case the client will collect digits from the user and then send the INVITE. Shortly after sending the Invite a NOTIFY will be received marking the group as active.

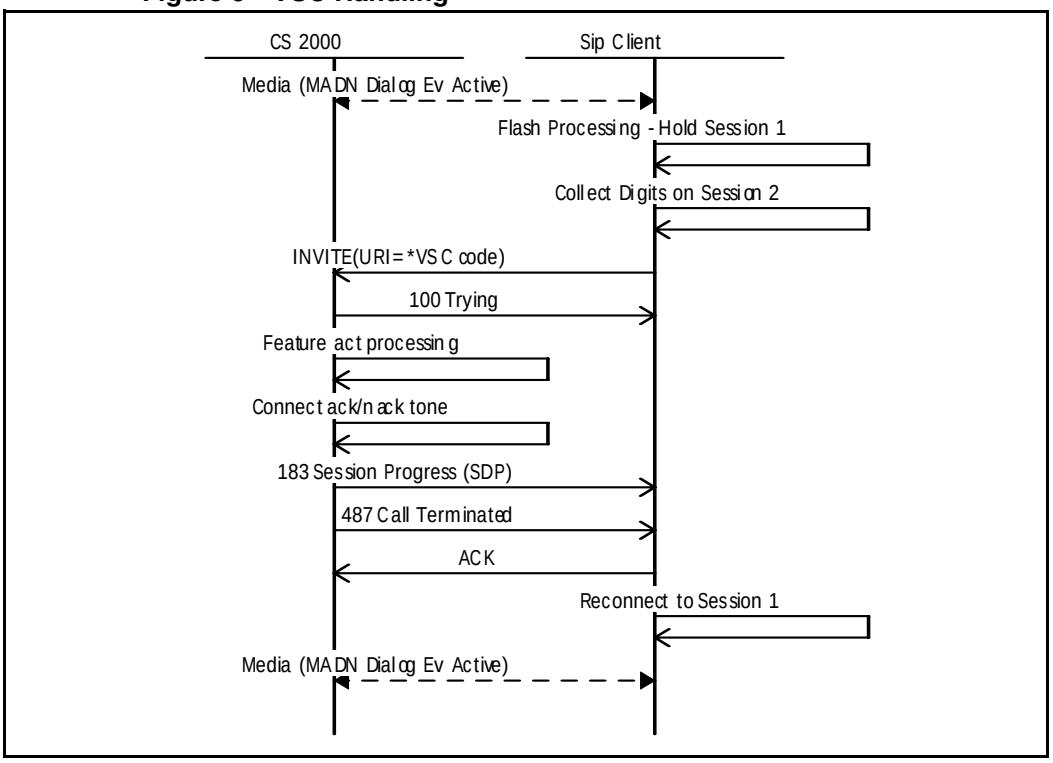
Figure 5 Outbound Call



149.4.5 VSC Call

MADN has imbedded features MHOLD and PRL which must be handled via Vertical Service Codes (VSCs) during active calls in the MADN group. For a MADN member participating in the MADN call (active media stream), the client is expected to handle Flash + digits processing, and send those digits to the CS 2000 for processing. The CS 2000 will evaluate the digits and process accordingly, connecting the VSC session to Ack or Nack tone, and then providing instruction to collapse the VSC call. The client is then expected to reconnect the media path to the original session.

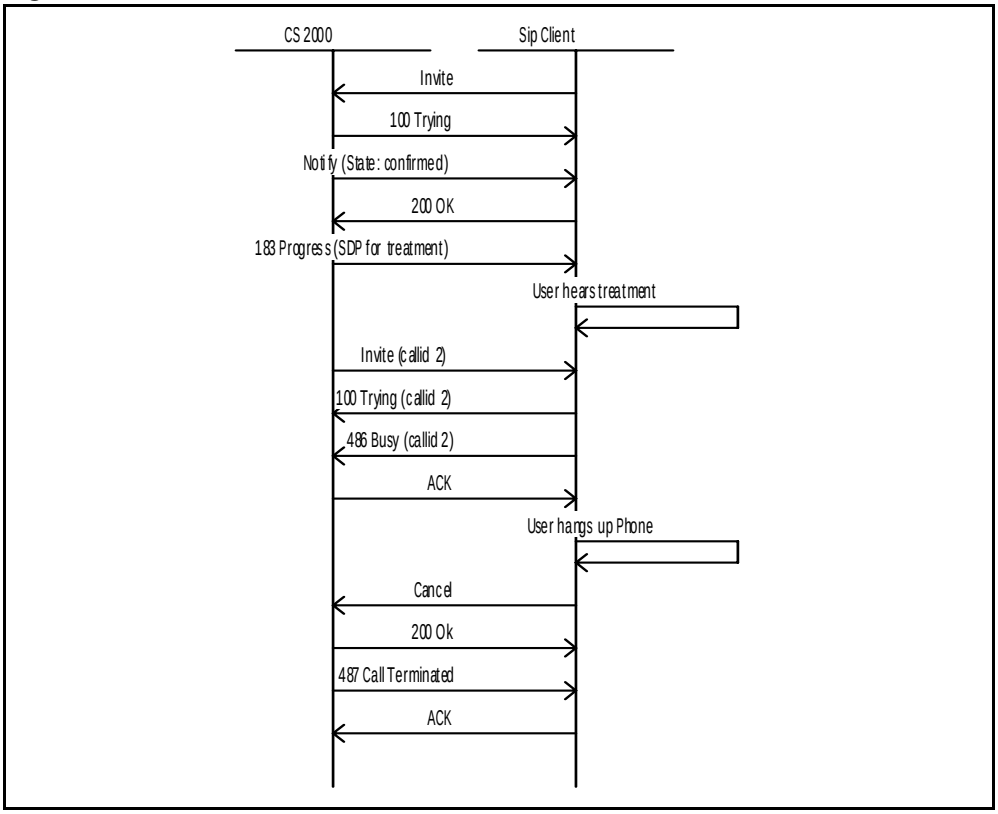
Figure 6 VSC Handling



149.4.5.1 Race Conditions

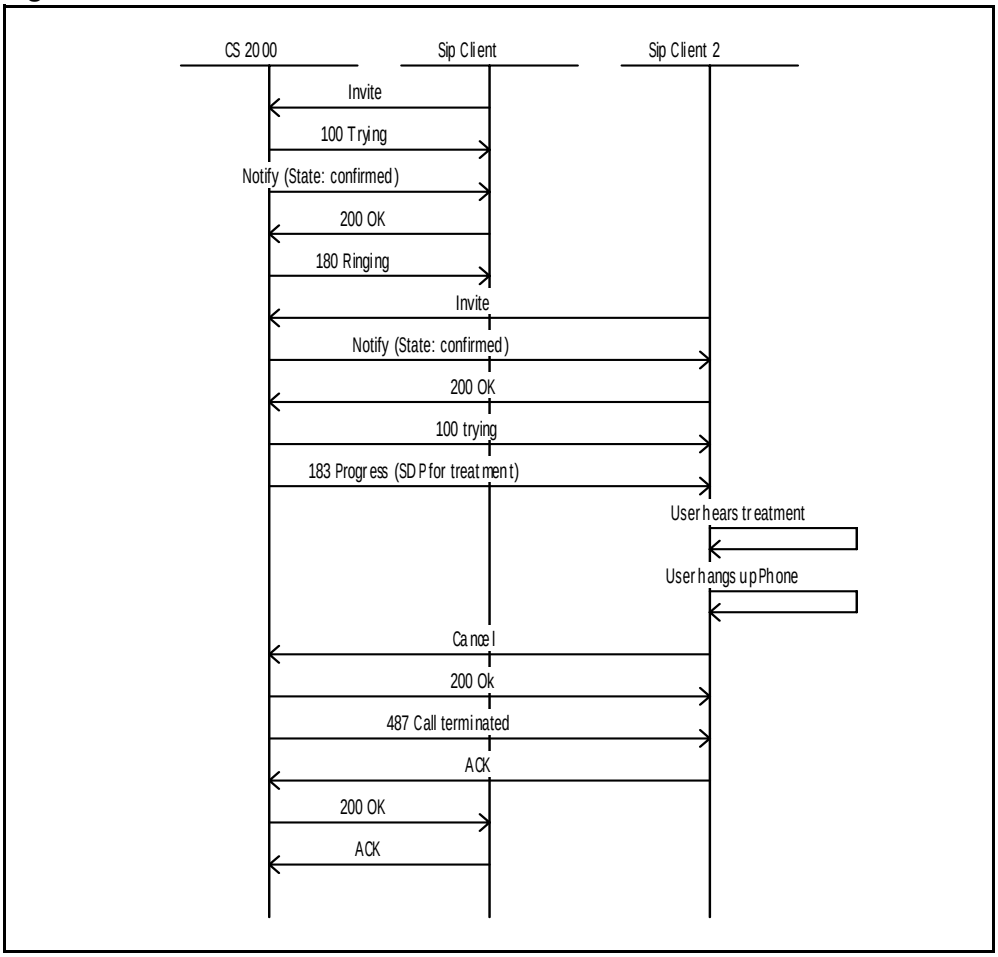
There are really two race conditions that will commonly occur. The first occurs when placing an Inbound call and an outbound call pass on the wire. The Outbound call will be given treatment. The inbound call will then be delivered to the client. How the client behaves depends on the client. The assumption is that the client will send 486 busy to the Inbound call and the user will hang up the call getting treatment. After hanging up the call if the user takes the phone off hook this should be treated as a bridging request and the user will end up answering the call. The call flow is shown below up to the point of the bridging request:

Figure 7 Inbound/Outbound Race



The other major race condition is two clients attempting to perform outbound calls simultaneously. In this case the clients call who arrives second will be given treatment and denied the origination. This case looks like the above but the call flow is a little different.

Figure 8 Dual Outbound call race



149.5 Limitations and restrictions

- This feature supports a limited set of SIP devices. Only SIP client devices which adhere to the SIP Client Requirements laid out in this document will be supported.
- MADN Engineering Rules as they apply to SIP Lines with the DPL option are as follows:
  - — MADN groups can have 32 members in either SCA arrangements
  - — no more than 16 members of the same MADN group can appear on a single GWC
  - — all members of a MADN group must belong to the same customer group

- No support for multiple SIP sessions with the exception of a second session invoking a Vertical Service Code (VSC) feature during an active / stable call
- The following MADN options, suboptions and subfeatures are not supported on SIP clients:
  - MCA - Multiple Call Arrangement
  - CACH - Call Appearance Call Handling
  - EXB - Extension Bridging
  - MRFM - MADN Ring Forward Manual
  - MRF - MADN Ring Forward
  - CFMDN - Call Forward MDN Secondary Members - MCA
  - MLAMP - MADN Lamp
  - PRV - MADN Privacy
  - MHOLD - MADN HOLD

Note: MHOLD is not supported in 09FF; however Hold will be supported through client based hold.

Note: MRF is not supported in 09FF; however RF will be supported through client based RF.

Note: MDNNAME and MEMDISP will be supported only for non-DPL lines.

149.6 Interactions

- If a SIP client is provisioned with MADN group and the client comes into service while the MADN group is ringing, that member will be notified the MADN dialog is active, but it will not be instructed to apply ringing.
- If a MADN group is comprised solely of SIP clients, there is the possibility that all members of the group could reject a call termination attempt. If this occurs, the originator of the call will be sent to reorder treatment. With non-functional originators (i.e. 2500 sets) there are scenarios where the originator may hear audible ringing and then be sent to treatment when the SIP line terminator rejects the call.

149.7 Query Commands

The query commands allow you to perform various existing queries.

Command format:

- qdn <DN>
- qlen <LEN>

- qsip <DN,LEN>

Command usage:

To Query a DN

>>qdn 6213101

New term	Definition

150: Functional Description (FN) A00012386

150.1 Feature name and Feature ID

A00012386 - Media Gateway 9000 Public Key Infrastructure

150.2 Description

This feature tracks the development and implementation of various Public Key Infrastructure features on the MG9K for IP security (IPsec).

IP security is employed to protect traffic flow between endpoints on a network. This standard protocol accomplishes this task by first authenticating the endpoint involved (verify endpoint identity) and also by encrypting the transmitted data. Public Key Infrastructure (PKI) is a standard that allows entities to establish trust relationships between endpoints and thereby aids authentication. For this feature, the MG9K IPsec interfaces will use a digital certificate to authenticate the peers with which it establishes IPsec sessions.

MG9K will use PKI to authenticate its IPsec sessions to the Element Manager (EM) and to the Gateway Controller (GWC). These channels are also known as the OAMP and signaling channels respectively.

150.3 Hardware Requirements or Dependencies

This feature is restricted to IP capable ITP controller cards.

150.4 Software Requirements or Dependencies

The Element Manager and the Gateway controller loads must be PKI capable.

150.5 Limitations and restrictions

None.

150.6 Interactions

As with previous releases, the user will use the Local Craft Interface (LCI) to configure IPsec on the DCC cards. The LCI screens were modified to allow the user to select the authentication method, the options being Pre-shared key and Digital certificate. A similar change was made to the MG9K EM VMG security view.

151: Functional Description (FN) A00012390

151.1 Feature name and Feature ID

A00012390 - Call Transfer Screening for SIP Lines

151.2 Description

This feature provides the call transfer screening support for the SIP Lines. The Call Transfer feature is developed in the DMS-CORE for SIP Lines under the DPL feature and this feature enhances the functionality by providing the screening functionality.

The screening service is provided for both the Blind and the Consultation Call Transfers.The screening will be specific to the DPL Lines agents or ONT. The Call Transfer and the screening function for TDM Line agents will remain unaffected.

The screening function will be triggered when the REFER(RFC 3515) message from the SIP Lines agent is conveyed to the CS2000 core as a feature message. The REFER message can be initiated when the user is in a single established call to make a Blind Transfer call or it can be initiated when the user is involved in two legs of call (the second one may be in a Ringing state).

The Call Transfer screening check components are discussed below.

151.2.1 Provisioning CXR for SIP Lines

Provisioning of the customer group or/and the SIP Line agent with specific screening suboptions. The subscription on the SIP Line agent will override the flavor of Call Transfer for the Customer Group to which the SIP Line agent belongs.

- The SIP Line provisioning is supported in the same way as it is for TDM Lines.
- The Call Transfer flavors will be processed only after checking if the call transfer type provisioned for the Line initiating the REFER. If the SIP Line is not provisioned with CXR option then the customer group provisioning is checked. A default value of CTINTRA for option CXFER is stored internally. Unless datafill is specified for this option, the default option is not displayed in the table CUSTSTN.
- The CXRRCL suboption is allowed while provisioning but ignored for CXR processing.

- The CXR method is allowed for provisioning, but only the STD method is supported for SIP Lines.The Figure 1 “CXR Provisioning for SIP Lines” on page 1468 shows an example for servord provisioning of the SIP Line.

Figure 1 CXR Provisioning for SIP Lines

```
> SERVORD
SO:
> ADO
SONUMBER: NOW 89 90 12 AM
>
DN_OR_LEN:
> 6216052
OPTION:
> CXR
CXFERTYP:
> CTALL
CXRRCL:[1]
> N
METHOD:
> STD
OPTION:
> $
COMMAND AS ENTERED:
ADO NOW 89 90 12 AM 6216052 (CXR CTALL N STD) $
ENTER Y TO CONFIRM, N TO REJECT OR E TO EDIT
> Y
```

1 - The CXRRCL option will be prompted for during provisioning of the SIP Lines, but the sub-option will be ignored in the CXR processing of the call.

151.2.2 Call Transfer Screening Process

- Checking first leg call type (Intragroup, Extragroup) whose party is being transferred to the second leg and its type.
- Compare them with the provisioned data for the flavour of call transfer.
- The Call transfer screening in case of Blind CXR will reject or allow the second leg origination after screening is done on receiving the REFER from the SIP Line agent.
- In case of consultation call transfer (when two call legs exist from the REFER initiating agent) the call transfer is just rejected and SIP Line

initiating the REFER will be appropriately notified. The call legs remains same as they were before the Call Transfer screening was initiated.

151.3 Hardware Requirements or Dependencies

N/A

151.4 Software Requirements or Dependencies

The call transfer screening development will be targeted to DPL Line agents. The Consultation Transfer call is NOT supported in Rel SN08 and its implementation in SN09 is out of scope for this feature. The CXR screening functionality will support the consultation transfer when it is available for SIP Lines.

151.5 Limitations and restrictions

- The Call Transfer service on the CORE for SIP Lines is a client or User agent initiated REFER handler service which will have all the interactions with the basic call as applicable to SIP Lines.
- The Call Transfer Recall functionality will not be supported for SIP Lines. The provisioning of CXRRCL sub option with the CXR option will be allowed, but the CXR Screening process will ignore the value of CXRRCL
- Consultation Call Transfer support for SIP Lines is not in the scope for the Call transfer Screening feature.

151.6 Interactions

The SIP Line call transfer screening will interact with all the services which SIP Lines supports.The Call Transfer service as implemented for the SIP Lines on the Core will have interactions as for a SIP Line basic call.

152: Functional Description (FN) A00012402

152.1 Feature name and Feature ID

A00012402 - 911 Hold/Ringback Support on SIP Lines

152.2 Description

152.2.1 Overview

This activity will implement the support for the following two E911 features on SIP Lines in SN09:

- E911 Network Hold
- Ringback

The scope of this feature is provide implementation of the above mentioned features on SIP Lines for two types of SIP User Agents. First being a 911 Enabled SIP UA, such as an ONT (Optical Network Terminal) and the second being a generic SIP Client with no support for 911 specific behavior.

152.2.2 Brief description of 911 Hold and Ringback features

- **E911 Network Hold**

The Network Hold feature provides the ability to hold the Network of the 911 call in the event that the Network goes on-hook prior to disconnect from PSAP operator. If the Network Hold is present in the network the PSAP operator will hear a tone to indicate that a caller has gone on-hook and the hold has been activated.

The session and the call resources will be held in the network until ether:

- The PSAP operator releases the call.
- SIP Client reconnects to the original 911 session.
  - — For 911 Enabled SIP Users, since the session is also put on hold in the client, the client will be reconnected to the 911 session as soon as the off-hook is detected.
  - — In case of other generic SIP UAs, where all the media resources have been released, the user will be reconnected to the prior 911 session only when he attempts to make a new call.

In the CS2000 Network the Network Hold is a controlled by the ORIGHOLD subfield provisionable on the E911 incoming trunks to the E911 Tandem. Both

MF and ISUP IT with the E911 Option trunks provide the support for Network Hold.

Example of ORIGHOLD option datafilled on the ISUP IT incoming trunk to the E911 Tandem is as follows:

```
TABLE: TRKGRP
>pos e911ics7
E911ICS7 IT 0 ELO NCRT IC NIL MIDL 613 AT1 NSCR 613 613 000 N N
(E911 0747 113 E911_STD N Y 0 0 Y) $
                                   ORIGHOLD bool
```

- **Ringback**

Gives the E911 PSAP operator the ability to ring the 911 caller back who has gone on-hook and who is being held by the Network Hold Feature. It also provides the ability to, at any point, send the receive off hook (ROH) to the caller's phone set which is off hook.

Ringback is controlled by the RBACK feature option assignment in the E911 Tandem found in table IBNXLA.

152.2.3 E911 Call Setup.

152.2.3.1 E911 Call Setup with 911 Enabled as the SIP UA.

911 Enabled SIP UA Dial plan specifically identifies the digit string '911' as an Emergency call. For such calls a combination of "Resource-Priority" and "Priority:Emergency" headers will be included in all sip INVITE messages sent to and received from the CS2000.

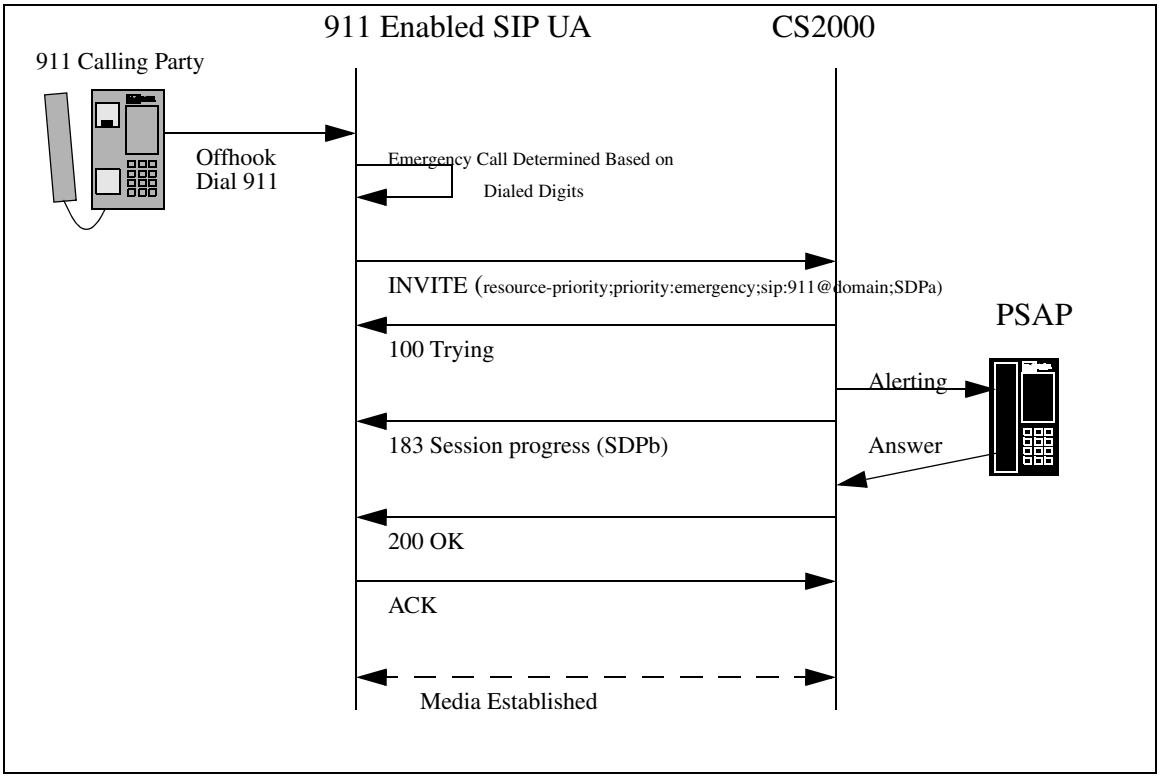
The Priority Header provided by the SIP UA client in the initial INVITE and all subsequent INVITEs will allow the CS2000 to differentiate between the 911 Enabled and generic SIP clients. The differences in 911 call processing by having Priority Header included in INVITE messaging are as follows:

- During the initial call setup, INVITE messages received with Resource and Priority Headers will receive preferential handling by CS2000 Overload Controls and thus will less likely to be rejected during overload times.
- INVITE with a 0 SDP and a Resource and Priority Headers received from a 911 Enabled SIP UA will be handled as a "Network Hold" Request for the 911 session and processed as such. The session and all its resources will be put on hold.
- An INVITE with 0 SDP and with NO Priority Header received during an established 911 session will be handled as a regular hold request (which are not supported on 911 calls) and thus will be denied. CS2000 will respond

with a 403 Forbidden message to deny the request. Figure 5 illustrates the message flow.

Figure 1 illustrates the messaging exchange occurring during the setup of the E911 Call when 911 Enabled SIP US is present in the network.

Figure 1 911 Call Setup with 911 Enabled SIP UA

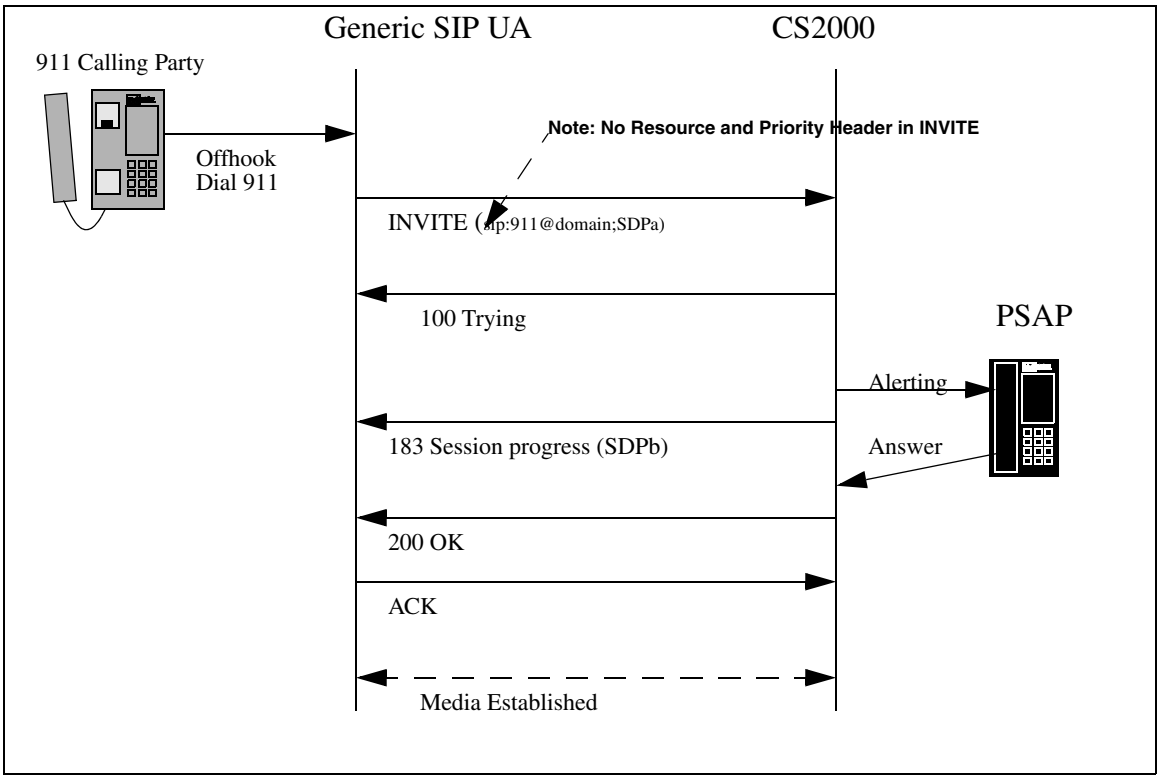


152.2.3.2 E911 Call Setup with a Generic SIP UA

Figure 2 illustrates the messaging exchange that occurs during the setup of the E911 call with a generic SIP UA. In contrast with the messaging received from the 911 Enabled SIP UA, there is no Resource-Priority and Priority:Emergency Headers in the sip INVITE received by the CS2000.

The main impact of not having these headers during the initial 911 call setup, is that the 911 call will NOT receive any preferential treatment from the CS2000 during the call setup stage.

Figure 2 911 Call Setup- Generic SIP UA



152.2.4 Caller Disconnect Message Handling

152.2.4.1 911 Caller Disconnect on 911 Enabled SIP UAs

Call flow in Figure 3 illustrates the disconnect/ message handling on the 911 Enabled SIP UA. The Handling of an invalid hold request is shown in Figure 4.

Upon detecting on hook from the 911 user, the SIP UA maintains all call resources and places the session on hold. An INVITE with 0 SDP and a combination of resource and priority headers is sent to CS2000 to request the session to be held. In the event that these headers are not included in the INVITE with 0 SDP, the hold request will be denied by the CS2000 and a sip 403 will be returned. See Figure 4.

Once the session has been successful put on hold, it will remain on hold until either the PSAP operator disconnects, or the 911 caller tries to re-connect to the session.

While the session is on hold, any incoming calls to the SIP user will receive BUSY Tone.

Figure 3 Disconnect Handling on the 911 Enabled SIP UA

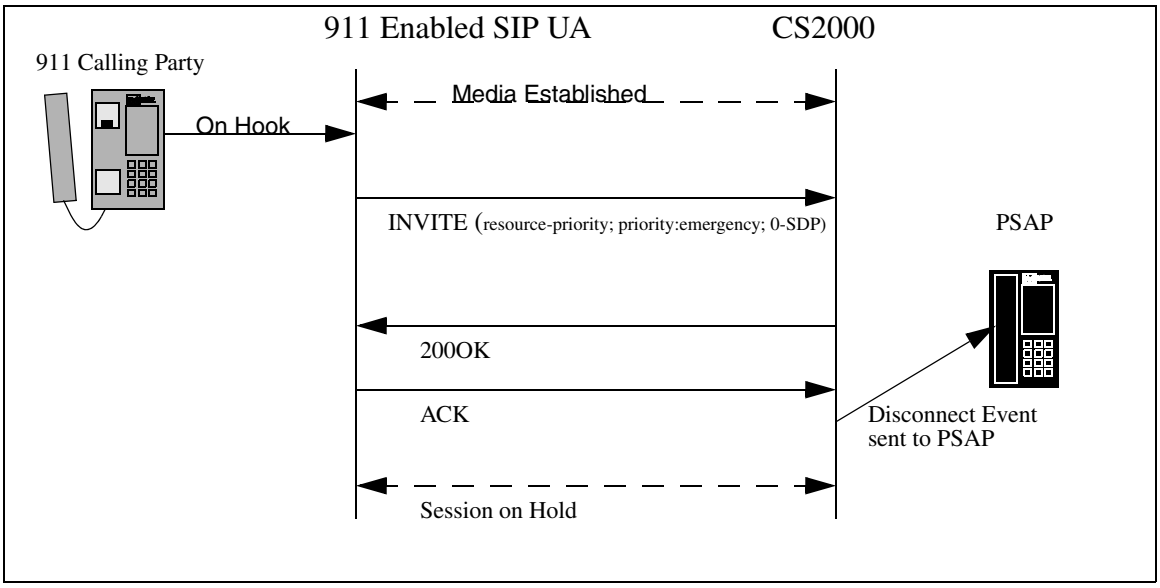


Figure 4 Invalid Hold Request

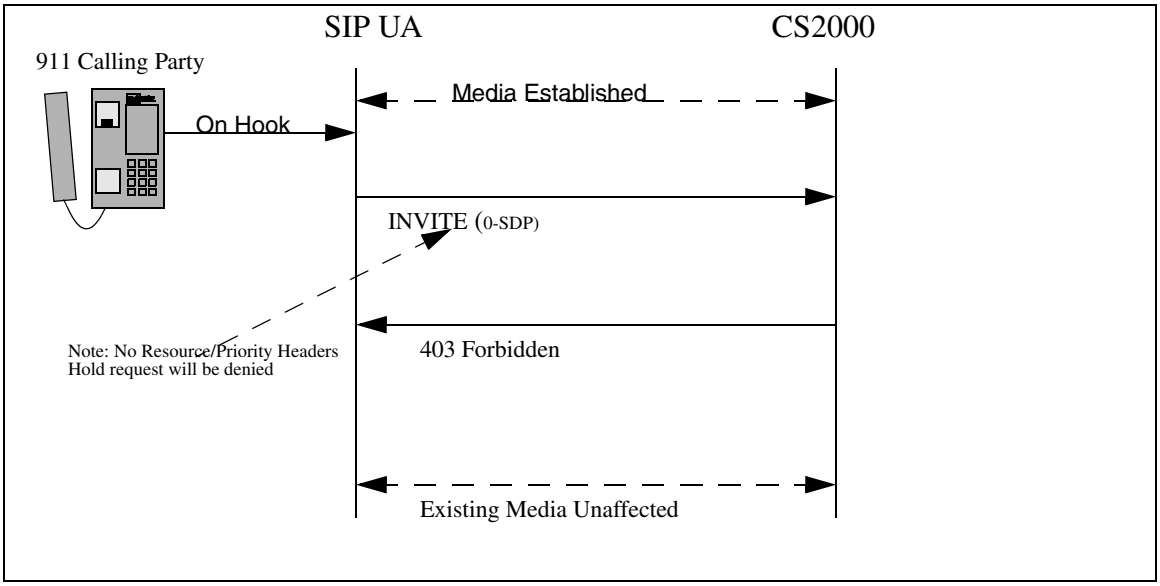


152.2.4.2 911 Caller Disconnect - Generic SIP UA Scenario

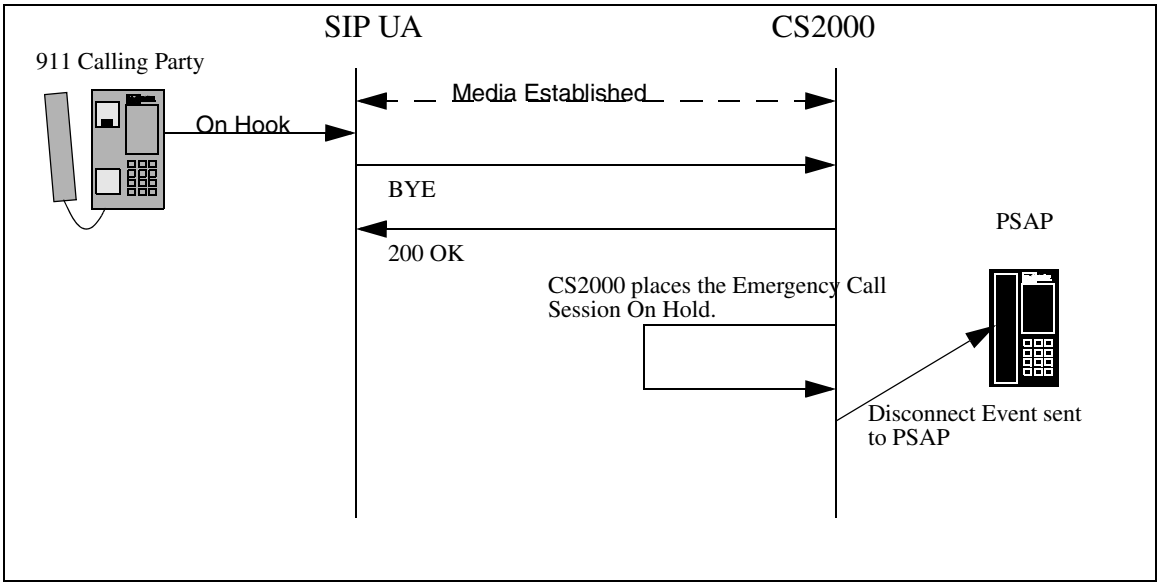
For generic SIP clients the user disconnect handling is illustrated in Figure 5. Typically SIP UA's don't have the logic to differentiate between 911 and regular calls and thus will take their media resources down as soon as the on-hook from the set is detected but prior to sending the BYE to the CS2000. This behavior makes it necessary for CS2000 to support the sip BYE message as a

request for network hold. Upon receipt of the BYE message the CS2000 session resources would be placed on hold and the PSAP operator notified of user's disconnect.

The session resources on the CS2000 will be held until either the PSAP operator disconnects, or the 911 caller goes off-hook and tries to originate a call.

While the session is on hold, any incoming calls to the SIP user will be sent to BUSY treatment.

Figure 5 Disconnect Handling - Generic SIP UA



152.2.5 Reconnect Following Activation of Network Hold

The 911 caller can "reconnect" to the existing 911 session by either of the following methods:

- If the SIP UA is 911 Enabled, simply going off-hook will re-establish the 911 session.
- In the Generic SIP UA scenario, the user will need to go off-hook and attempt to originate a call. SC2000 will respond to the incoming INVITE by reconnecting the client to the previous session.

Figures 6 and 7 illustrate the possible message flows for the reconnect scenarios.

Figure 6 Reconnect Handling with 911 Enabled SIP UA in the Network

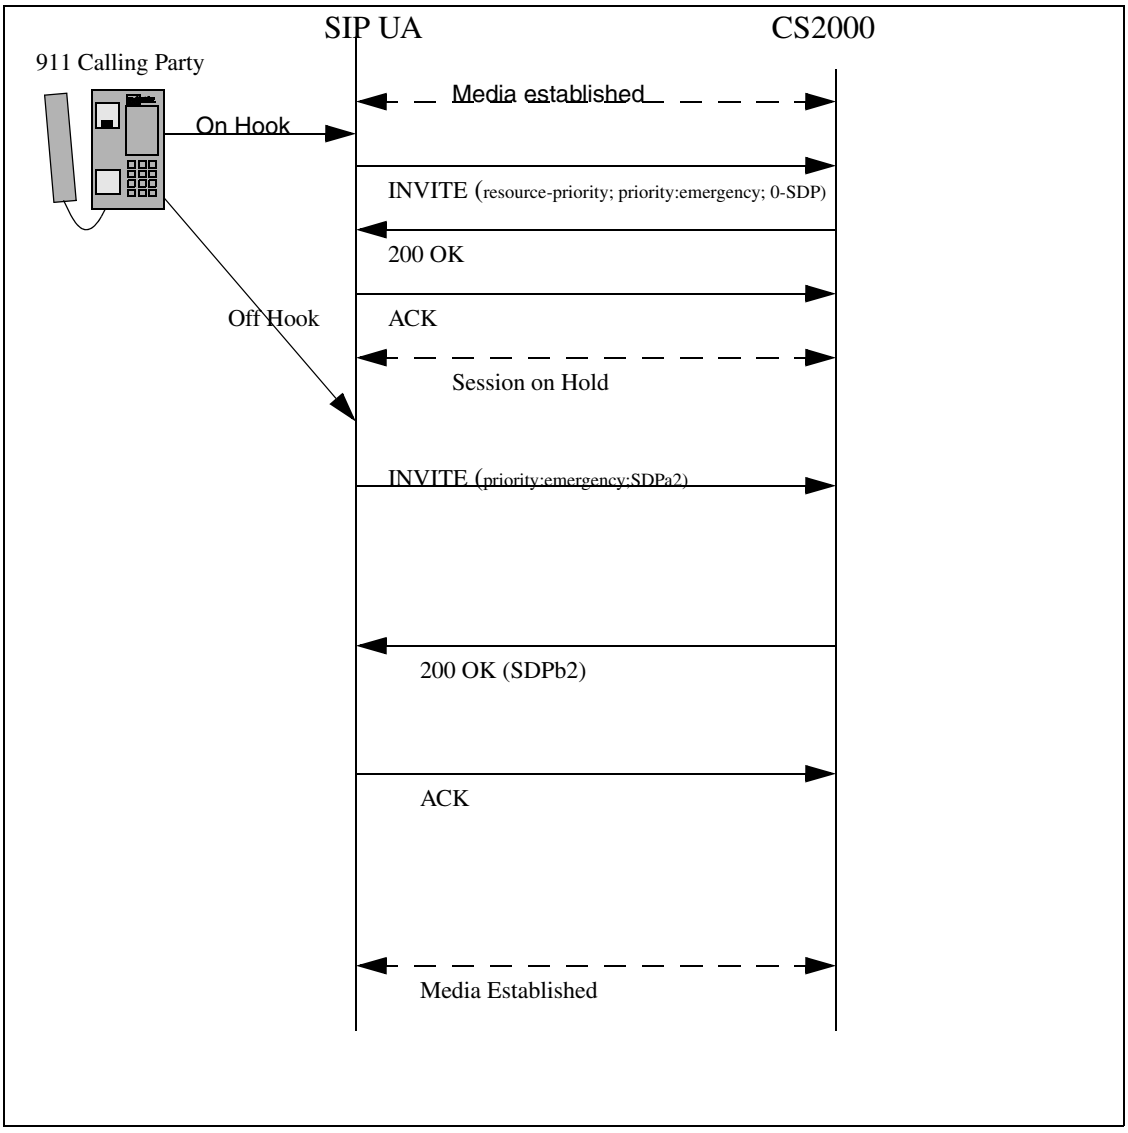


Figure 7 Reconnect Handling - Generic SIP UA

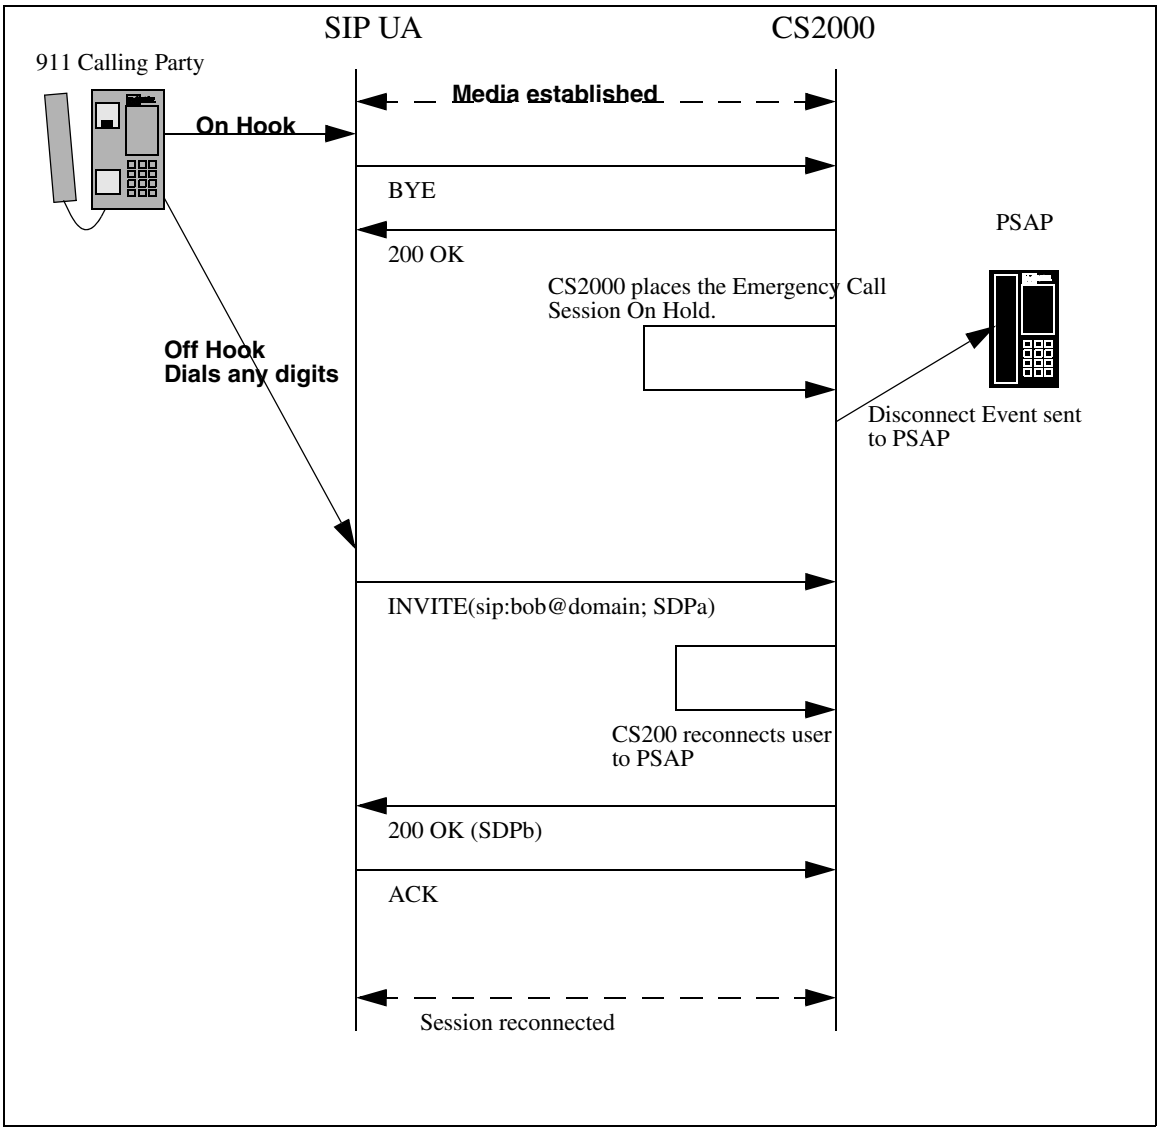
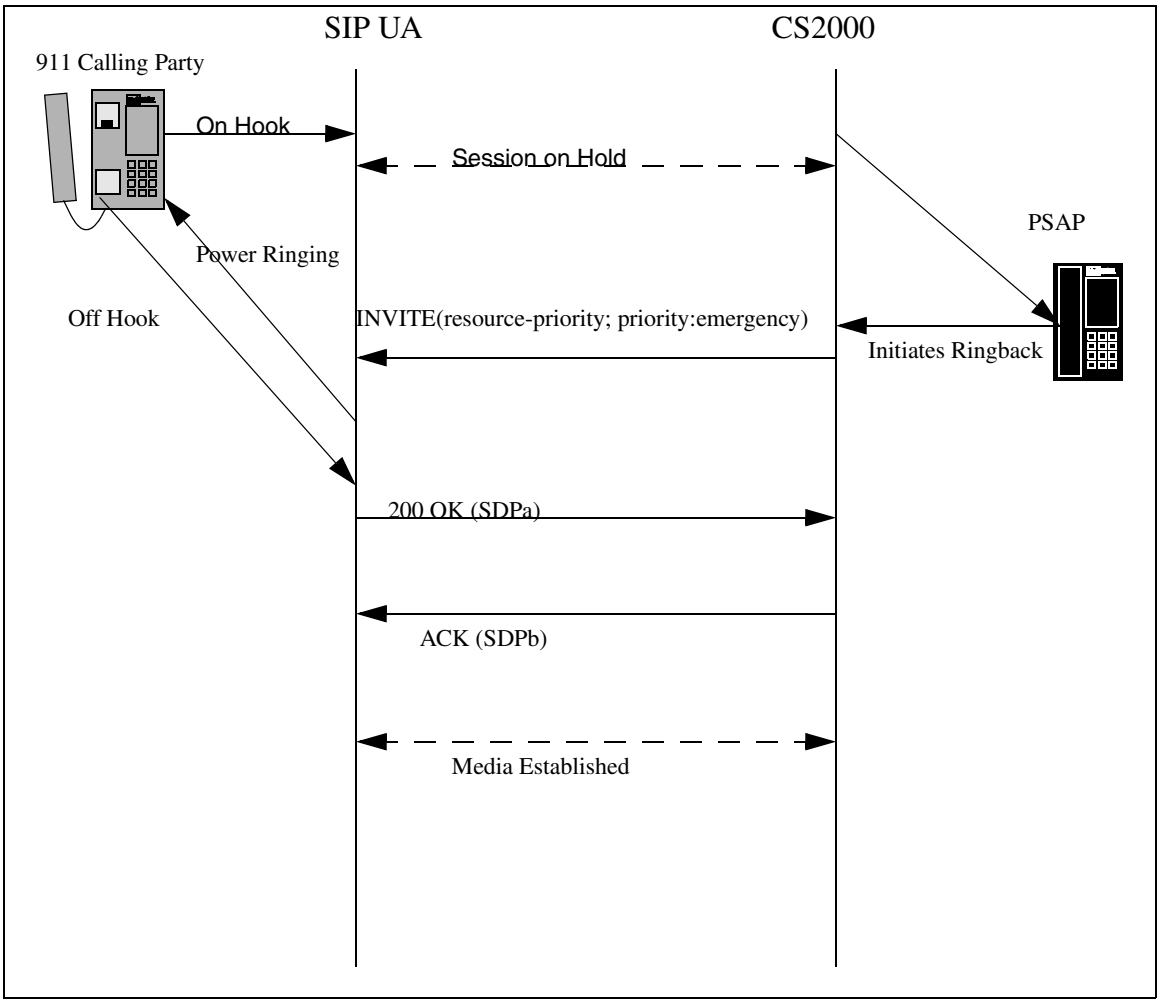


152.2.6 Ringback Activation following Network Hold

At any point while the call is being held the E911 PSAP operator can ring the 911 caller back. Once Ringback is activated, the CS2000 restores the held session and the SIP UA applies power ringing to the user's set.

Once the session is placed on hold, there is no difference in the message flows between the 911 Enabled SIP UA and other SIP UAs.

Figure 8 Ringback Handling in the Network

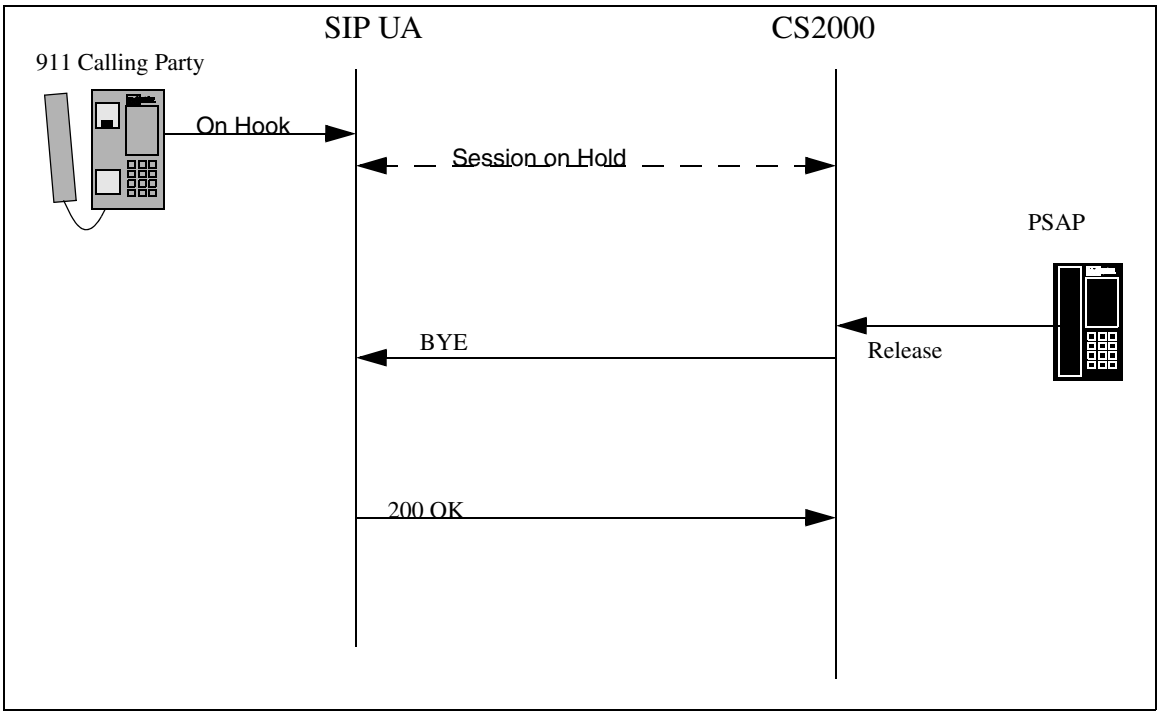


152.2.7 PSAP Disconnects following Network Hold

At any point while the call is being held the E911 PSAP operator can disconnect the session by going on hook

Figure 9 illustrates a Release received from the PSAP following the onhook from the SIP UA.

Figure 9 PSAP Disconnect Handling in the Network



152.3 Hardware Requirements or Dependencies

No new hardware dependencies are introduced beyond the general requirements for SIP Lines

152.4 Software Requirements or Dependencies

In addition to the general software requirements for SIP Lines and E911, this feature also introduces the support for the 911 Enabled SIP UA. Such a SIP UA differs from other Agents in that it has the smarts to identify emergency calls and handle them accordingly.

911 Enabled SIP UA's Dial plan specifically identifies the digit string '911' as an Emergency call. For such calls the "Resource-Priority" and "Priority:Emergency" Headers will be included in all sip INVITE messages sent to the CS2000.

The 911 Enabled SIP UA Service Profile will have the following a following provisionable boolean parameter: Emergency Call On-Hook Hold. If On-Hook Hold is set to true, then the on-hook from the 911 caller will be treated like a call hold and all session resources will be held. Once the On-Hook is detected an INVITE with the "Resource-Priority" and "Priority:Emergency" Headers and 0 SDP will be sent to CS2000 to request the hold.

Since PSAP can at any point request to alert the caller, the 911 Enabled SIP UA will either provide a distinctive power ringing if the Network's set is off-hook or a "howler" tone if the set is on-hook.

152.5 Limitations and restrictions

In case where a BYE message is received from SIP UA and the session is being held in the CS2000, simply going off hook by the user will not cause the session to be reconnected. The user will need to dial digits and an INVITE (sip:cdn@domain) will need to be received by CS2000 in order to reconnect the user to the PSAP operator.

152.6 Interactions

CS2000 will require the "911 Enabled" SIP UAs support all behaviors outlined above.

153: Functional Description (FN) A00012403

153.1 Feature name and Feature ID

A00012403 - Data Protection for SIP Lines

153.2 Description

This feature inherits all functionality from legacy lines.

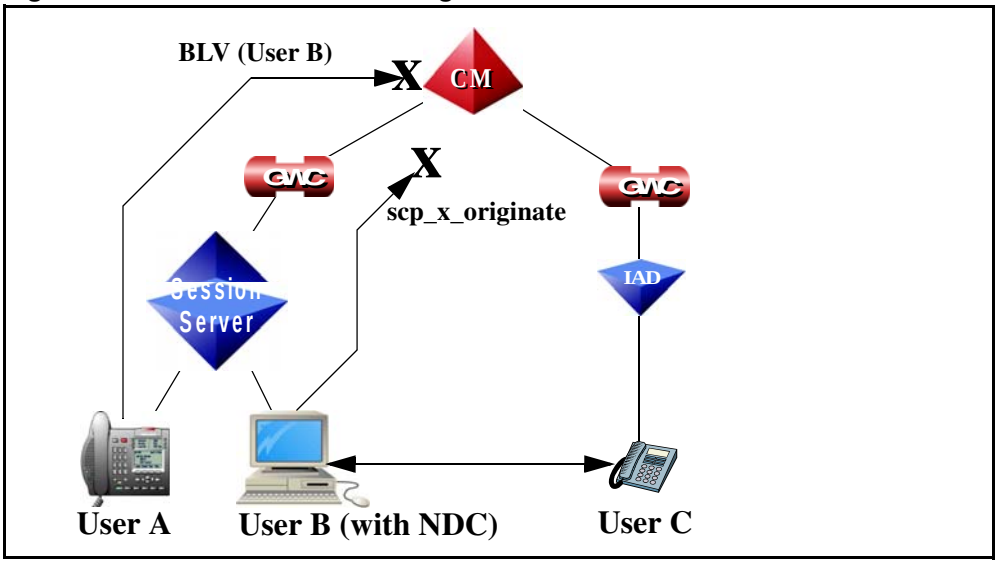
Data protection prevents interruption or mutilation of data calls caused by the application of warning tones and voice energy associated with attendant camp-on, busy verification, busy override and call waiting.

Data protection is provided by assigning the No Double Connect (NDC) option to a line. A line assigned NDC, cannot use the call transfer, or any of the conference features, nor participate when invoked from another subscriber. This option prevents the user of such a line from providing access to data or to computers from other, possibly unauthorized lines.

The NDC option is activated/deactivated via Data Modification Order (DMO).

No Double Connect (NDC) option has two roles: First is to prevent a user with NDC assigned from making multiple calls, Second is to ensure any feature that is incompatible with NDC does not operate on a user with NDC option.

Figure 1 Functional Behavior Diagram



User B (with NDC option) is in a call with User C. User A is prevented from activating a feature (e.g. Busy Line Verification) against User B. User B is prevented from making a new origination.

153.3 Hardware Requirements or Dependencies

None.

153.4 Software Requirements or Dependencies

None.

153.5 Limitations and restrictions

The NDC option is not compatible with the following line options:

This component is to validate the feature is compatible with the No Double Connect (NDC) option. Certain features cannot be assigned to a line with NDC option. These features are as follows:

3WC, 3WCPUB, CHD, CNF, CRT,CWD, CWI, CWO, CWT, CWTC, CWX, CXR, DCBX, DSCWID, FXR, HLD, LDSA, LDSO, LDSR, LDST, LNPTST, MPB, PCWT, PRK, VOWDN[1].

Incompatibility is assigned through table OPTOPT.

153.6 Interactions

Camp-on is not compatible with stations that have NDC assigned. If the customer group parameter is comp-on with tone, camp-on will not apply to stations assigned option NDC.

Call Transfer and Blind Call Transfer is not compatible with NDC.

Busy Verification is denied to stations assigned NDC.

Call Waiting, Call Waiting Origination, and Dial Call Waiting are incompatible with lines assigned NDC option.

Directed Call Pickup-Barge In is incompatible with lines assigned NDC option.

Executive Busy Override, also known as Executive Right of Way, Executive Busy Override, Executive Override, Override, Break-In, Barge-In, is incompatible with lines assigned NDC option.

Trunk Busy Verify is incompatible with NDC option, when the busy circuit is connected to a line with NDC option.

[1]See Glossary for Definition.

Click to Call, and PA Simring are not compatible with NDC. (These services must have 3WC option).

When the client device is programmed with 3xx/Redirect/Call Forward All, the NDC check will be made against the client as well as the target to which the redirect occurs.

153.8 Glossary

Term	Description
New term	Definition
3WC	Three Way Calling. The 3WC option allows the subscriber, on the assigned line, to place a call on hold. When the call is on hold, the subscriber can set up a request call to another subscriber. The subscriber that initiates the three-way call can switch speech paths between the held party and the talking party. The subscriber can connect all parties into a three port conference. When the three way call is in progress, the subscriber can drop the conference. When the subscriber drops the conference, the subscriber connects to a single-party call again.
3WCPUB	Three Way Calling Public Announcement. The 3WCPUB option allows all parties on a call extension from a 50B customer premises system (CPS) to bridge together. The parties do not wait for the controlling party to flash all the parties together.

Term	Description
CHD	Call Hold. The Call Hold (CHD) option allows a subscriber with a 500/2500 set to hold a call. If a party does not go off-hook, the subscriber can hold a call for any period of time. When this action occurs, the station with CHD can perform other tasks. These tasks include speed call programming or call pickup, as a call holds. The subscriber can only put one call on hold at a time.
CNF	Station Controlled Conference. The station Controlled Conference (CNF) option allows a station to have a conference call to a maximum of 30 parties. With the CNF option, the station does not require the help of an attendant for a conference call to a maximum of 30 parties. The members of the conference can belong to the same customer group or belong to different customer groups. The members also can belong to a station on a trunk. The JOIN option works with CNF to add a held party to a conference without having to hang up and redial the held party. CNF is a prerequisite to adding JOIN to the business set.
CRT	Call Redirect. Call Redirect (CRT) provides residential subscribers with the ability to transfer calls to a predefined routing directory number (DN) or to a voice mail DN. The transfer occurs when the subscriber flashes and dials the CRT access code during an established two-party call. After su8ccessful feature activation, the subscriber receives a confirmation treatment. Only the terminator in a two-party call can activate CRT. After activating, the terminator becomes the CRT controller.
CWD	The Dial Call Waiting (CWD) option allows a business set user to impose call waiting on a busy station. The busy station can be a 500/2500 set or a business set with a call waiting (CWT) feature key.
CWI	The Call Waiting Intragroup (CWI) option allows a subscriber to apply the CWT option to intragroup calls, in addition to those allowed with CWT.
CWO	The Call Waiting Originating (CWO) option allows an originating line to impose a call waiting tone automatically on a busy line.
CWT	The Call Waiting (CWT) option allows the system to alert a busy station when an incoming call attempts to reach the directory number (DN).
CWTC	The Call Waiting Conference (CWTC) option allows the subscriber to conference a waiting party.
CWX	The Call Waiting Exempt (CWX) option does not allow Dial Call Waiting (CWD) and Call Waiting Originating (CWO) to interrupt a business set user.
CXR	The call transfer option (CXR) allows the assignment of a call transfer type other than the type that the customer group has.

Term	Description
DCBX	The Directed Call Pickup Barge-In Exempt (DCBX) option allows a station to block the attempts of other stations with DCBI assigned to barge in.
DSCWID	Deluxe Spontaneous Call Waiting Identification (DSCWID) allows the subscriber to receive calling-party information during call waiting. The subscriber also receives this information with basic SCWID. The DSCWID presents the subscriber with a set of option to treat the incoming calls. These options include the following: - Answer the new call and put the current call on hold. - Disconnect the call. Answer the new call. - Forward the new call. - Connect the new call to a busy announcement. - Conference the new call with the current call.
FXR	The Fast Transfer (FXR) option reduces the number of keystrokes required to transfer a call. The user does not need o conference all parties before the user transfers calls.
HLD	The Permanent Hold (HLD) option allows a single-line set to put an active call on hold and return the handset to the handset cradle. The party on hold hears a ringback tone, a recorded announcement, music, or silence.
LDSA	The long distance signal activate (LDSA) line option (activation code *49 or 1149) allows the end user to activate or deactivate Long Distance Alerting (LDA) on a line. The operating company personnel can assign the LDSA line option through SERVORD.
LDSO	The Long Distance Signal Option (LDSO) option provides Long Distance Alerting (LDA) subscribers with a different ring and a different tone.
LDSR	The Long Distance Signal Ringing (LDSR) option provides Long Distance Alerting Enhancement (LDAE) subscribers with a a distinctive ring when the subscriber line is idle.
LDST	The Long Distance Signal Tone (LDST) option provides Long Distance Alerting Enhancement (LDAE) subscribers with a distinctive ring when the subscriber line is busy.
LNPTST	The system assigns the local number portability test (LNPTST) option to a single-party residential (1FR RES) line to allow a local number portability (LNP) test call. The system assigns this option through SERVORD. The SERVORD blocks subscription to this option by any other type of line. The only line option compatible with LNPTST is Digitone (DGT). The SERVORD does not allow assignment of LNPTST and line options that are not compatible on the same line.

Term	Description
MPB	The Multi-Party Bridging (MPB) option allows a multi-party group with a maximum of four subscribers with a different line equipment to associate in a multiparty group. The liens appear to the subscribers to be different parties of a multiparty line. Each member of a MPB group has a different directory number and a different line equipment number. The MPB option creates a bridge among subscriber lines that wires cannot bridge. Wires cannot bridge subscriber lines because these lines do not have analog appearance in the central office. An example of these lines are lines that connect to an integrated digital loop carrier.
PCWT	The Precedence Call Waiting Terminating
PRK	The Call Park (PRK) option allows a business user to park a call against the directory number (DN) of the user. Retrieval of the parked call can occur from any station. When the call is parked, the user can originate and receive calls on that DN.
VOWDN	The Virtual Office Worker (VOW) feature allows telecommuters who do not have dedicated physical phone sets to access their dedicated directory number (DN) and associated features and options. They do this by logging into their dedicated DN from any of a pre-designated group of phone sets. Once logged in, all features and options operate normally, and all calls to the dedicated DN terminate to the set on which the login occurred. All predesignated sets that are to be used by VOWs need to have the VOWDN line option assigned within the customer groups that are to offer VOW functionality. The VOWDN option is not compatible with any other line options/features except SETMODEL, DGT, DISP, M0200, and NAME.

154: Functional Description (FN) A00012410

154.1 Feature name and Feature ID

A00012410 - Support SIP lines for Malicious Call Hold

154.2 Description

This feature expands the existing Malicious Call Hold (which is datafilled as the CLF option), service supported in the CS2K Core to SIP Lines.

A line with the CLF (Calling Line Identification with Flash) option, activates and deactivates the CLF functionality with a flash and VSC (Vertical Service Code). The line is the terminating party of the call. The Core generates a log and records information about the Originator of the MCH caller.

When the terminating agent of the SIP lines, initiates the MCH feature, a message with an authorization code is sent to the CS2K The CS2K will terminate the call and service the request action.

154.3 Hardware Requirements or Dependencies

Not Applicable

154.4 Software Requirements or Dependencies

Not Applicable

154.5 Limitations and restrictions

The following are the restrictions and limitations of this service:

- This MCH feature will be initiated on a SIP Client that has only one call prior to invoking the malicious call feature.
- This MCH feature will only supported for 2 (two) calls on the same VSC. That is, if the client enter the VSC with more than 2 calls, then the feature will not be activated.
- This feature will support any client that has been integrated with the CS2K
- B party control in not part of NA MCH feature.

154.6 Interactions

All existing MCH interactions works the same way with the SIP Lines. No new interaction anticipated.

154.7 Glossary

Term	Description
CLF	Clear Line Identification with Flash
MCH	Malicious Call Hold
NA	North American
VSC	Vertical Service Code
SIP	Simple Internet Protocol

155: Functional Description (FN) A00012470

155.1 Feature name and Feature ID

A00012470 Compact Call Agent - Support for NA/Intl Hybrid Market

A00012766: SDM/CBM800 connected with BRISC to CBM850 connected with CCA cutover.

Note: The scope of the requirements has been expanded to include both North American and International markets.

155.2 Description

155.2.1 Overview

This activity supports the Packet Ready 2005 (PR-2005) marketing initiative to convert existing BRISC (SNSE70EM, SN70EM) core offices to CS-2000 Compact (CCA) based Hybrid offices.

The cutover activity builds on the procedures already supported for CS-2100 Compact (Enterprise) who have supported the BRISC to Compact cutover since the SE06 release.

The following additional components are supported over the CS-2100 Hybrid:

- SDM or CBM-800 on the BRISC are converted to CBM-850 connected to the Compact during the overall cutover process.
  This is developed as part of activity A00012766.
  (The requirement to cutover from an SDM on BRISC, to the same SDM on CCA is being addressed by the SDM/CBM team as a post-SN09FF activity.)
- ICM (Intelligent Call Manager) EIU application is supported over the cutover from BRISC to CS-2000 Compact. However, given the lack of a secure IP address on the CCA for use the ICM application, it is recommended that the use of this functionality be limited to ICM systems that are securely connected to the CCA (for example, the ICM system is in the same office, or connected to the same private network as the CCA).
- As part of ICM compact support, an additional external (publicly routable) IP address is supplied as the Core address for ICM. This IP address is hardened and filtered for security purposes. This is currently seen as an SN10 activity, and is not currently supported as part of this activity.
- There is no longer any need to migrate FLIS based SS7 links to a USP-Compact after the core cutover. FLIS based SS7 links are supported on the CCA after the cutover.

- Baseline for the cutover is (I)SN09. This requires that the TDM office be brought up to (I)SN09 baseline prior to beginning the compact cutover.
- The set of PMs and applications supported in CS 2000 Compact is slightly different than in CS2100 Compact.

155.2.2 Office Cutover\

155.2.2.1 Cutover Strategy

The strategy for performing the CM to Compact-Core cutover for the North American and International Markets is based on CM to XA-Core Cutover methodology and on previous development done to support CM to Compact Core in ISN06/SE06.

All of these procedures are based on the existing software upgrade methodology (One Night Process, or ONP). This core-to-core ONP is accomplished by having the Compact-Core behave as an “inactive” CPU, while the CM Core behaves as the “active” CPU. Data and activity can then be transferred to the new core by a TABXFR, PRESWACT, and NoRestartCutover, similar to those processes used during a standard ONP.

The cutover tools assist the personnel involved in installation and software delivery to manage the retrofit process throughout the entire retrofit. The tools are delivered on the *NONRES Installation/Commissioning Tools Tape or CD* as a set of loadable modules that and are loaded onto both the CM and Compact cores for the duration of the cutover. After the Compact-Core cutover has been completed, the tools are removed.

A special cutover hardware tool called the Cut-Over Device (COD) which was developed for the CM to XA-Core cutover is also used. The COD acts as a switchbox in the links from both the CM and Compact Cores to the MS. It performs conversion of the DS-512 and OC-3 protocols used between the CM and Compact-Core and the MS respectively. The COD simplifies and increases the reliability of the Cutover procedure by making it easy to switch individual links between the CM and Compact Cores, test for the correct link connectivity, setup a data transfer link between the two cores, and perform a switch of activity (SWACT) between the two cores.

In the CM to Compact Call Agent Cutover procedure, the CODs are installed in a portable XA-Core shelf. There are both SNSE and SN versions of the CODs. (Figure 4)

155.2.2.2 ICM Cutover Overview

To support ICM over the Core cutover requires that the ICM systems be shutdown briefly, and the Core IP address be changed to the CCA core address, and the system is restarted once the Core Cutover has occurred. There are many ICM configurations possible, involving Nortel or 3rd party ICM systems, which may or may not be operating through a proxy. These systems

are usually located on the ICM customer premises. There may be several ICM systems supported off the DMS.

As part of the planning activities for the cutover, the ICM customer(s) must be involved to capture the specifics of their ICM configurations, to review the plan for the cutover, and to secure their participation in the pre-testing and night of cutover activities. They must also participate in any changes required to firewall rules in order to support connectivity to the new Core IP address.

ICM connectivity pre-test will be performed a few days prior to the night of cutover. This involves testing ICM connectivity to the CCA from within the office, and also from the customer sites. It is recommended that each ICM customer should perform the steps to pretest ICM connectivity to the CCA from their site, in concert with the onsite tech.

On the night of cutover, the ICM customer will execute the ICM cutover steps for their ICM system, coordinated with the actual core cutover.

155.2.2.3 Synopsis

The purpose of this activity is to provide support to convert an office running (I)SN09 on a CM core to (I)SN09FF running on a Compact core.

Also, provides support to convert an SDM/CBM800 running in SN09 to CBM850 running SN09FF load in parallel with the conversion of CM core to Compact Call Agent.

There are many aspects to this cutover, (roughly in order of execution), including:

- Advance Planning and Preparation
- Bring office h/w to SN06 baseline, upgrade it to supported hardware and s/w to SN06 baseline, s/w upgrade to SN09, as required.
- Upgrading MS hardware and software to baseline as required during the procedure.
- Load and Tool Delivery
- Commissioning the new Compact Core (including the Core and IO blades, Disk storage server, and LAN).
- Installing and Commissioning/Configuring the new CBM850 and establish the communication to newly commissioned CCA (IMs and NTPs are provided in the section **3.2.3.4.3**).
- Installation of specialized cutover tools to aid in the process.
- Integration of Cutover devices (CODs)
- MS Boot Testing
- Integration of the DMS/TDM LAN with the CS-LAN IP network

- Perform the downstream connectivity testing from CBM850.
- Perform the billing application pretest on CCA and CBM850.
- ICM connectivity pre-testing to the CCA
- ManB all the CBM850 applications.
- Transferring and converting switch data from the CM to the Compact Core.
- Rts all the CBM850 applications.
- Make sure that the SBA schedules are activated.
- Prepare ICM for cutover.
- Switching activity from the CM core to the Compact Core.
- Perform the billing application post test on CCA and CBM850.
- Switching ICM applications from communicating with the core via the TDM LAN EIU to the CCA. Bring ICM systems insv, and perform call testing.
- If downstream is configured on the SDM/CBM800, send the billing files to downstream.
- Bsy and OffL the DS512/OC3 card on the CCA, which is used for connecting the SDM/CBM800.
- Removal of the cutover tools, including CODs, upgrade the MS CMIC cards to OC-3.
- Removal of TDM EIU LAN equipment.
- Decommissioning the CM core.
- Optional consolidation of LAN equipment.

155.2.2.4 Procedure Overview

Figure 1, "Cutover Procedure Summary of Activities and Impact" below gives an overview of the end to end cutover procedure. Notice that there are activities occurring both before and after the Night of Cutover (Z-date). The overall time frame listed in the figure is an approximation only. Actual time frames are determined by the Installation team in consultation with the customer and are captured in the CM-Compact Cutovers Planning Guide.

The procedure supports Single Cabinet Compact configurations (Non-Geographic Survivable).

Figure 1 Cutover Procedure Summary of Activities and Impact

Office Configuration	Activity in Office	Impact to Customer	Timeline
	**Baselining/Installation/Commissioning**		
	• Upgrade office to h/w and s/w baseline for cutover: may include as required: - JNET to ENET conversion - Migrate to supported PMs - S/W upgrades	• Various, depending on upgrade procedure	• Z-30-Z-15 •
	• Upgrade MS hardware to baseline	• MS Simplex for h/w upgrade (1-2 hrs)	
	• Commission CCA & ERS	• No impact to inservice office	• Z-14
	• Install & Commission CBM850.	• No impact to inservice office	• Z-13 •
	**Integration/Data Transfer Phase**		
	• Integrate CODs in CMIC links	• Each MS Link OOS during integration	• Z-5
	• Perform MS Boot Testing	• Each MS in simplex for 2 hours	• Z-4, Z-3
	• Integrate ERS8600 into TDM-side LAN	• No impact to inservice ofc.	• Z-2
	• Appl pretest CCA-CBM850	•	•
	• ICM connectivity pre-test	No impact to inservice ofc.	• Z-2
	• Establish Data Transfer Config. - one COD is switched to CCA	• No impact to inservice ofc.	•
	• Transfer SLM data to CCA via SLMXFR	Office runs with three MS-core-links for duration of data transfer	Z (Day/ Night of Cutover)
	• Setup Volume mapping (volalias)		
	• Perform ONP TABXFR, EIU IP Tables not transferred	• CM remains InSync	
	**Switch of Activity Phase**		
	• Establish Cutover SWACT config.- Two CODs are switched to CCA	• Office runs with two MS-core-links	• Z (Day/ Night of Cutover)
	• Prepare ICM for cutover	•	
	• Prepare CBM-850 appls for cutover	•	
	• Switch activity to CCA via NoRestartCutover	• TSI < 15s; PSIs < 30;Two MS-core-links, EIU IP Applications < 5min.	
	• Switch Remaining CODs to CCA		
	• Verify CBM850 applications		
	• ICM cutover to new Core IP	•	
	• Remove NIIKEY Files	•	
	**De-Commissioning Phase**		
	• De-integrate CODs, install OC3 PB's on MS CMICs	• MS Simplex for 1 hour.	• Z+2, Z+3
	• De-Integrate TDM LAN from EIU		•
	• Remove EIU datafill from CCA		•
	• Decommission EIU		•
	•		• Z+4-5
	• Decommission CM/SLM		• Z+7
			• Z+7
	Z=Cutover Night		

155.2.2.5 Components

The following sections describe the components of the Hybrid cutover. They are roughly in order of execution,.

155.2.2.5.1 Software and Hardware Baseline

This portion of the activity identifies the Software and Hardware baseline required as the starting configuration. If necessary, activities may be needed pre-cutover to bring the office to baseline. For example, if a JNET office is to be converted, it would need to be upgraded to an ENET prior to applying the CM to Compact Cutover procedure.

Examples of upgrades that might be required:

- JNET to ENET conversion
- CM hardware upgrades to SN70EM or SNSE70EM
- Migration of services away from unsupported PMs to supported PMs (for example - moving from Series 1 PMs to XPMs)
- DPP/BMC conversion to CBM-800.
- Software upgrade of the entire office to (I)SN09 baseline

End goal is to have the office on the (I)SN09 s/w release with only hardware supported over the cutover.

Supported hardware:

- SNSE70EM or SN70EM BRISC processor
- ENET
- CBM800 or SDM
- IOM
- Series II peripherals: MTM, SMS, ESMU, SMU, ESMA, SMA, LGC, RSCS, LTC, LGCi, DTC, LTCi, SPM, DTCI, IW-SPM

155.2.2.5.2 MS Hardware and Software Upgrade

The following elements of the MS hardware are upgraded during the process, as required:

- MS Processor card upgraded to NT9X13DG (SN) or NT9X13NB (SNSE), (if required). This task is done as part of the office hardware base lining activities.
- MS CMIC Port cards upgraded to NT9X17AD (if required). This is done at the same time as the MS Processor card upgrade, during the hardware baselines phase.
- MS Mapper Card is updated if required.

- Each upgrade of the MS hardware requires the MS unit to be powered down during the card replacement.

155.2.2.5.3 Compact Core Commissioning

The compact core is installed and commissioned according to the installation IM. This portion of the system is commissioned prior to connecting it to the MS to begin the Cutover procedure.

Part of the commissioning process is to datafill the IP provisioning tables with the correct IP datafill for the Compact Core. The tables that need to be provisioned are:

- IPNETWRK[1]
- IPHOST

The other tables that were traditionally involved with IP provisioning on CM based cores are not required to be datafilled and are to be left empty. These are:

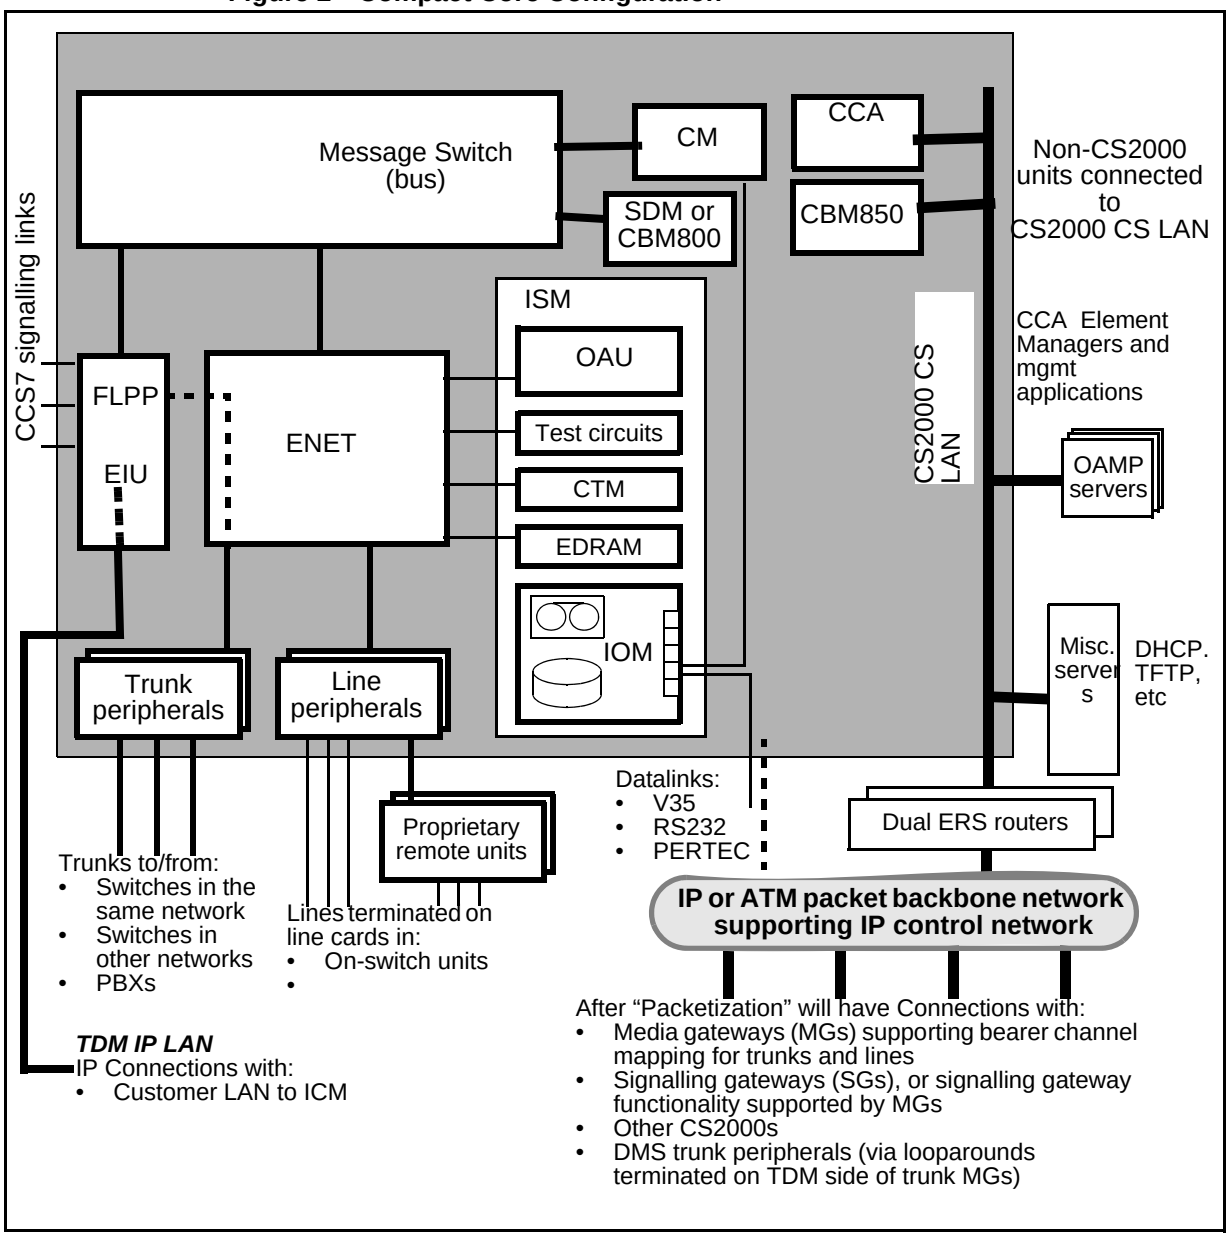
- IPROUTER
- IPTHRON
- IPPROTO
- RMCONFIG

At the end of this phase, and prior to COD and LAN integration, the Compact Core is set to be the Inactive Core using the NIIKEY files.

Figure 2, "Compact Core Configuration" shows the configuration after this step.

[1]The installer must be provided with he appropriate EFILEs to do this provisioning. IPNETWRK needs to have one IP address defined as well as the SCRNFLAG setting. The CM core can support up to 16 IP addresses. These will get collapsed down to one new Compact Core IP address.

Figure 2 Compact Core Configuration



155.2.2.5.4 CBM850 Commissioning and Configuring

The CBM850 is installed and configured according to the installation IM (24-2610) for the SN09 load. Establish the communication between newly commissioned Compact core and CBM850. Make sure that CBM850 communicates with Compact core.

Use the following NTPs/IMs to configure the applications on CBM850.

Table 1 CBM-850 Documents

Application	NTP/IM
CBM850 Commissioning	24-2610
Security and Administration	NN10358-611.03
SuperNode Billing Application	NN10363-811.03
GDD application	NN10353-511.03
Log Delivery Service	NN10353-511.03
OM Data Delivery	NN10361-711.03
Passport Log Streamer	NN10440-450
GR740PT	NN10440-450
DNBD Call Data Delivery (NA load)	NN10190-113
DNBD Call Data Delivery (International load)	NN10194-113 NN10449-113
DDMS	NN10347-461.03

Configure the DDMS applications on the CBM850. But, do not bring the DDMS applications (**OSS Comms Svcs & OSS and Application Svcs**) to InSv state on the CBM850.

Make sure all the other applications are inservice on the CBM850 after configuring them.

NOTE:

If downstream configuration required for the SBA and same downstream is used for both SDM/CBM800 and CBM850 systems, a new directory need to be created in the downstream for the CBM850 billing file transfer. While configuring the SBA schedules on CBM850 the new directory information has to be provided to avoid overwriting the billing files in the downstream.

SBA schedules can not be activated when there is no active stream running on CBM850. The schedules will be activated only during billing pretest.

WARNING

When SBA schedules are configured on CBM850, do not use the same downstream directory info used in SDM/CBM800 configurations. Create a new directory in the downstream system and configure the schedules with the new directory information to transfer the billing files to downstream.

155.2.2.5.5 Provisioning of New external Core IP address

A requirement for ICM on the CS 2000 Compact Hybrid is to have an externally visible IP address for the Core, to allow external ICM applications to communicate with the core. Since normally the Core IP address is only visible on the internal CS-LAN, the security of this new IP address is important.

This is currently being pursued as an SN10 activity.

In the interim, it is recommended that the cutover procedure be limited to offices with ICM systems that are either co-located with the CCA, or can be connected to the CS-LAN in a secure manner (for example, on the same private lan).

155.2.2.5.6 Load Delivery

Loads, and software tools are delivered on SLM tapes or CDs. The following are expected:

- CM cutover tools
- Compact-Core Cutover tools on CD.
- Compact-Core Loads on CD:
  - (I)SN09FF Compact-Core platform (LINUX) image and MC (Message Controller) image.
  - (I)SN09FF Compact-Core Application (SOS) and MS images.
- SN09FF CBM850

These loads, and software tools are transferred from tape or CD to SLM disk volume or Compact disk volume as appropriate.

155.2.2.5.7 Site Preparation

Site preparation includes activities such as:

- Verifying connectivity to the switch
- TABAUDIT - used to verify the validity and integrity of the table data

- PRECHECK - used to verify the switch preparedness for the ONP.

155.2.2.5.8 Cutover Software Tools Installation

During the Cutover Tools installation phase, the software tools are installed and initialized on both the CM and Compact cores. The software tools consist of loadable modules. Scripts are provided to facilitate the loading of the tools.

Two new modules (SDMCBMTG & CCACMDCM) are introduced in CM as part of the cutover tools for the SDM/CBM800 to CBM850 cutover activity. New loading and unloading scripts are introduced to load and unload the cutover tools on CM.

If billing pre-test need to be performed, then the following modules need to be transferred to the Compact Call Agent.

CRSGENUI
CRSGENP
CRSGENCI
BCRUGENI

loadcmtl: New script to load the cutover tools on the CM.

The list of modules require for the SN/SNSE CM core:
XARETNRG
XARCMDUI
XAMCLUI
XAMCLDAD
XAMCLKID
SLMXFRUI
SLMXFRBG
SLMXFRCI
VOLNAMUI
VOLNAMCI
CUTSWCT
CUTSWTCI
CUTTODTX
XARETCI
XAMCLCM
VOLNAMCM
CMMTCC
XARCMDCM
XARCLNCM
SDMCBMTG
CCACMDCM

unldcmtl: New script to unload the cutover tools on the CM

A brief summary of each of the commands, accessed via the XARETRO CI follows:

XARETINIT
This command initializes retrofit software and prepares the system software for an Compact Core retrofit.

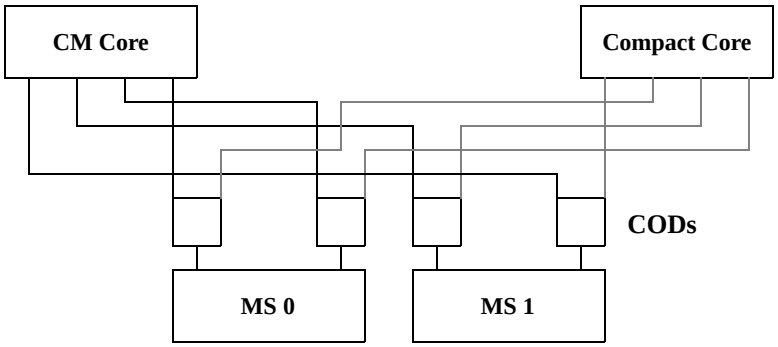
STATUS
This command provides a report of the state of the Compact Core retrofit. For each procedure within the retrofit procedure, a report is given on the progress which has been made.

LINKTEST
This command is used to test the CMIC links and to verify that they are able to carry messaging (see "Figure 3 Office Configuration with new CMIC links, CODs integrated" on page 1501 for a description of the links to be tested):

- the CM Core (Old Core) to COD links, the COD to MS links and the COD to Compact-Core (New Core) links for CM to Compact Cutovers.

Each link is tested separately, as the CODs are integrated.

Figure 3 Office Configuration with new CMIC links, CODs integrated



MATECORELINK
The MATECORELINK command is used to establish a communication path between the CM and CA cores. The communication path allows a graceful means to transfer office data and activity to the new core.

VOLALIAS
The VOLALIAS command is used to establish the name mapping from the CM SLM volume to the Compact Core disk volume. The SLM volume names are replaced with the corresponding Compact Core disk volume names.The SLM to Compact Core volume name translation mechanism is required to

eliminate mismatches in application data between the SLM volume name and the Compact Core disk volume name.

In addition to the above, Table Reformat support is provided to translate SLM volume names in office tables during TABXFR.

VOLNAMXFR
The VOLNAMXFR command is used to transfer the names of the SLM disk volume names from the CM to the Compact Core. This information is used to setup the FROM portion of the VOLALIAS volume mapping.

SLMXFR
This CI increment supports SLM file transfer activity from SLM disk to Compact Core disk during CM to Compact Core cutover. This is needed because the SuperNode/SNSE CM Core to Compact Core Retrofit will replace SLM disk and tape devices with NFS mounted disk volumes on the Compact Core.

CUTSWACTCI
This CI increment provides a mechanism similar to NORESTARTSWACT to be used for SuperNode/SNSE CM to Compact Core Cutover. Specifically the following commands are provided:

- NORESTARTCUTOVER - This performs the switch of activity from the old core to the new core. For Cutover, the NoRestartCutover switch of activity is from an insync SuperNode or SNSE CM core, to an insync Compact Core.

- SWACTTRAK - This provides a time trace of the activities occurring during the NoRestartCutover switch of activity.

RESET
The RESET command is used to reset the status of the policing software. This enables the user to begin a new retrofit without unloading and reloading the software tools.

CI@RTIF Function
A CIBINCOM interface is provided at the CM RTIF after the switch of activity to the compact core. This allows text based commands, including NODISP MAP commands, to be performed at the CM RTIF. This functionality allows executions of various commands required to prepare the CM core to initiate an abort cutover.

COREGOACTIVE
The COREGOACTIVE command can be performed on the CM core after a switch of activity to the compact core in order resume activity/callp on the CM core. This is used to support aborts back to the CM core. Impact is equivalent

to a COLD RESTART. It would be executed from the CI@RTIF prompt on the CM.

SUSPEND/RESUME
The SUSPEND and RESUME commands are used on the active CM core to either suspend or resume the cutover procedure respectively. The SUSPEND command is used by the TELCO to allow commands to be executed that would normally not be permitted during the retrofit window. Once these non-retrofit commands are completed, the cutover set of permissions can be resumed, via the RESUME command, without loss of cutover progress data. One example of commands that are normally disallowed during cutover is MATELINK RTS which would put the active CM core in splitting.

155.2.2.5.9 Cutover Device (COD) Integration

The cutover devices (CODs) are integrated into the MS links. The CODs are expected to be shipped to site in a Portable XA-Core cabinet. It is not necessary for the Compact cutover to have the portable XA-Core shelf populated with any of the XA-Core cards. Only the 4 CODs are needed in their correct slot positions.

“Figure 4 SuperNode COD” on page 1504 and “Figure 5 SNSE COD” on page 1505 show diagram of the SN and SNSE COD devices respectively. While the SN and SNSE CODs are very similar in appearance, they are not interchangeable. The type of COD is easily identified by the label **SN** or **SNSE** at the top of the COD. These labels are highlighted in the figures.

The toggle switch (S1) is used to switch the link from the CM to the XA positions. The XA position connects the MS to the Compact Core.

“Figure 6 COD locations on an XA-Core Shelf” on page 1506 shows a rear view of the XA-Core portable shelf showing the COD locations within the shelf. The CODs must be inserted in the correct slots:

- COD 0 - Slot 14R
- COD 1 - Slot 13R
- COD 2 - Slot 6R
- COD 3 - Slot 5R

Figure 4 SuperNode COD

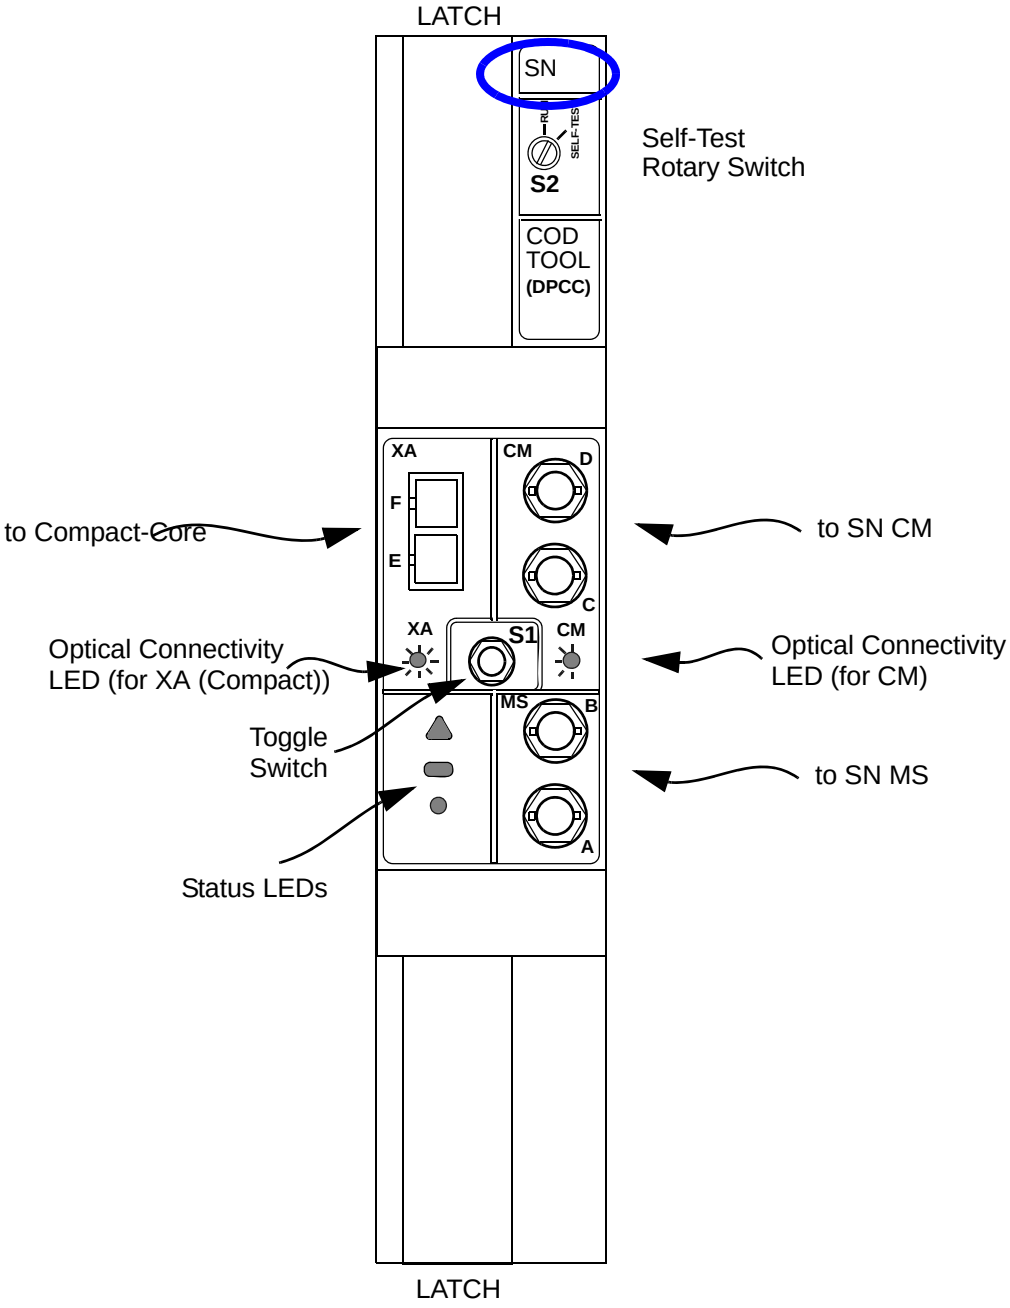


Figure 5 SNSE COD

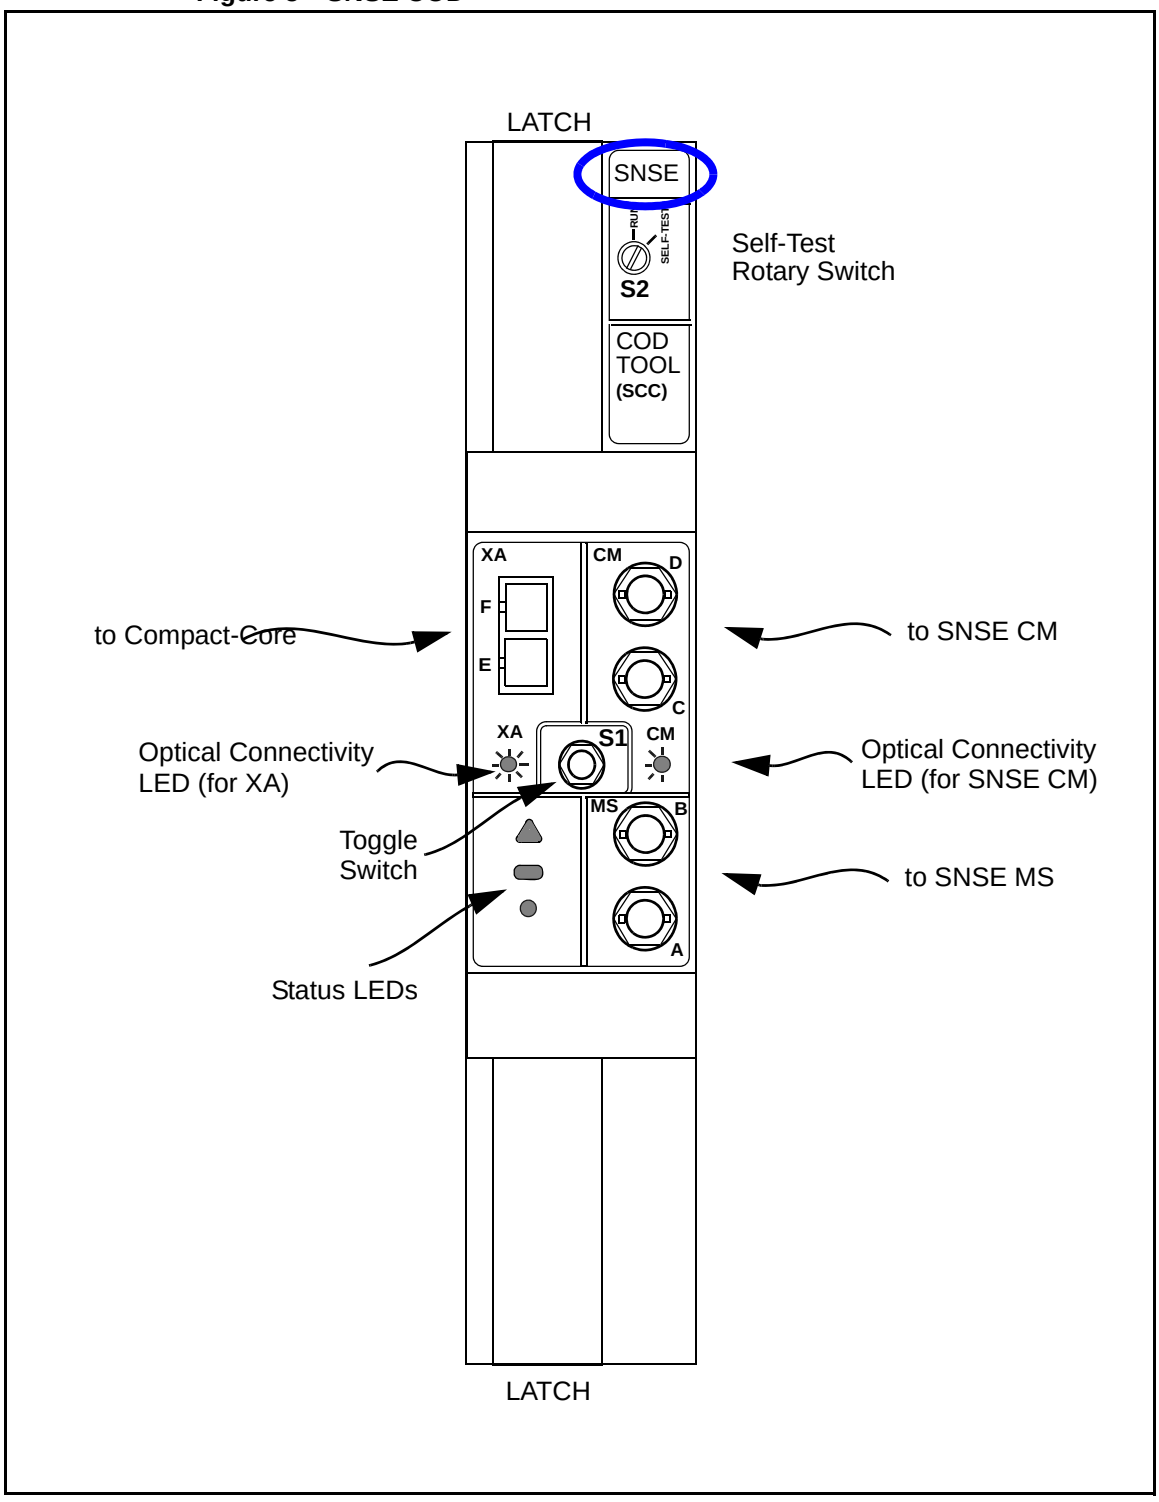

Figure 6 COD locations on an XA-Core Shelf

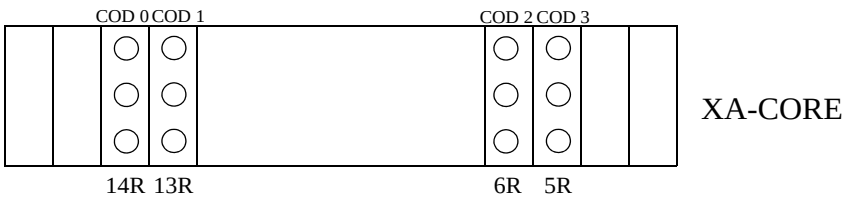

Rear View

155.2.2.5.10 MS BOOT testing

The MS boot testing procedure verifies connectivity between the Compact and the MSes, and ensures that the MSes can be loaded from the Compact.

In turn, each MS is BSYed on the CM side. The Compact core is booted active, with the appropriate CODs switched to the Compact side. The MS is booted over each CMIC link.

155.2.2.5.11 CBM-850 Application Pre-test

This procedure tests that the Compact can talk to the CBM-850 and that CBM applications can be successfully brought insv.

Make sure that all applications are InSv in the CBM850 except DDMS applications (**OSS Comms Svcs & OSS and Application Svcs**). This will ensure that the CBM850 applications are able to communicate with the CCA core.

Perform the downstream testing to make sure CBM850 can communicate with the downstream. Execute *ping* command on CBM850 with IP address of all the configured downstreams and make sure that the *ping* command works fine. This will ensure that CBM850 can communicate with all the configured downstream systems.

CBM850 Billing Pretest

This testing will be performed prior to the ONP to make sure billing records are transferred to CBM850 from CCA as well as to downstream from CBM850. Make sure that the applications on the CBM850 are configured and in-service.

- Setup of the MATECORELINK in the data transfer configuration (1 link to Compact).
- VOLNAMXFR to transfer the volume names from the CM to the Compact.
- VOLALIAS to provide a mapping from CM to Compact volume names.

Transfer Billing datafill
- Transfer the billing related tables from CM to Compact Core

ca_sos> xfronly CRSFMT
ca_sos> xfronly CRSMAP
ca_sos> xfronly SDMBILL

Disable MATECORELINK
- Bsy matecorelink
cm_map> xaretro
cm_map> matecorelink bsy

- Toggle the COD back to CM side
- Rts the CMIC port for the link on CM
  - SN CM : mapci;mtc;ms;shelf 0; card 25; rts 1 port 0
  - SNSE CM : mapci;mtc;ms;shelf 0; card 4; rts 1 port 1
- At this point all the COD switches should be toggled to CM.

Suspend XARETRO tool
- Suspend the tool until it is needed again.
cm_map> xaretro
cm_map> suspend

ca_sos> xaretro
ca_sos> suspend

Boot the CCA as Active
- Disable the NIIKEY
- Dump the IMAGE on CCA
- Set the boot file on CCA with the dumped image
- Reboot the Compact Call Agent blades

Perform the test
- Downloading of data dictionary successful
  >cbmmtc appl
    - verify that the application “tasl” is InSv
      (may take up to 15 minutes to download)
- Make sure that config data migration is done

Activate the SBA Schedules on CBM850:
- Follow the procedure given in **Appendix section 3.9.5** to activate the configured schedules.
- Verify that the schedules are activated using the procedure given in **Appendix section 3.9.6.**

Billing testing on CBM850 and Compact core:
- If AMA streams are configured
 - load the *crsgen* tool on Compact core (available as part of the cutover tools)
  ca_map> load crsgenui
  ca_map> load crsgenp
  ca_map> load crsgenci
  ca_map> load bcrugeni
  - with SBA InSv on the CBM850
  ca_map> crsgen ama setrate 200
  ca_map> crsgen ama start
  wait for 1 minute
  ca_map> crsgen ama stop

  - with SBA ManB on the CBM850
  ca_map> crsgen ama setrate 200
  ca_map> crsgen ama start
  wait for 1 minute
  ca_map> crsgen ama stop
 - RTS SBA on the CBM850 and perform the clean-up
 - unload the crsgen tool from CCA
  ca_map> unload bcrugeni
  ca_map> unload crsgenci
  ca_map> unload crsgenp
  ca_map> unload crsgenui
- If OCC stream is configured
  - with SBA InSv on the CBM850
  ca_map> cdrtst
  ca_map> cdrcrank 10 8 10

  - with SBA ManB on the CBM850
  ca_map> cdrtst
  ca_map> cdrcrank 10 8 10
 - RTS SBA on the CBM850 and perform the clean-up

Refer to the **Appendix section** of this feature for more detail on how to validate the Billing Normal and Backup modes.

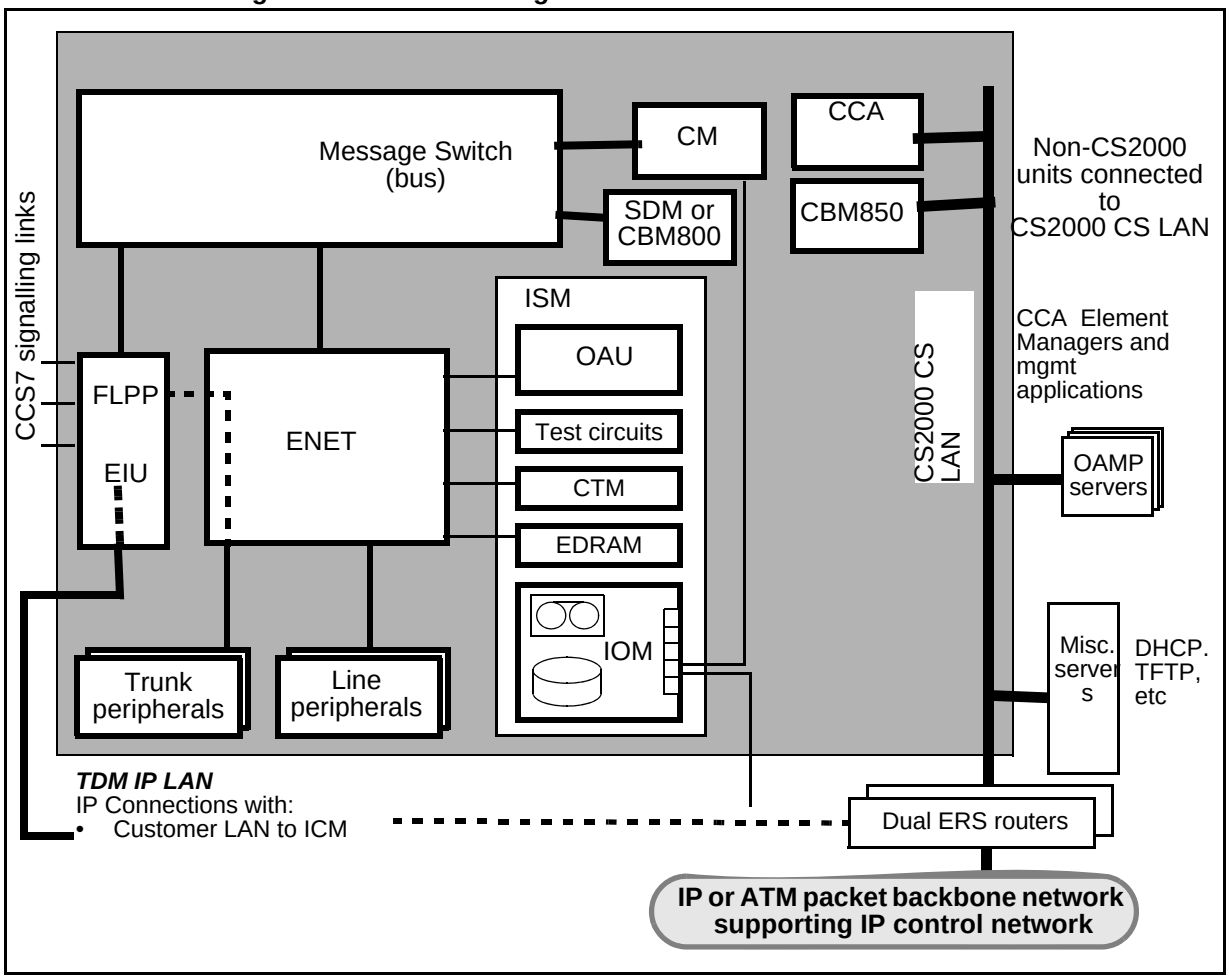
- Restore the matecore link back to CM (all the CODs are toggled to CM position).
- Boot the compact core as inactive with the patch current load prior to the ONP.

155.2.2.5.12 TDM LAN Integration with Packet LAN

During this phase any TDM LAN equipment is integrated into the packet LAN equipment.

Figure 7, "TDM LAN Integrated With Packet LAN" shows generically how the TDM LAN is integrated with the packet LAN. For each type of TDM LAN, the actual specifics will vary. A PC or other device should be used to test that the two LANs have been correctly integrated.After the integration, the IP traffic will continue to flow between the CM core and the down-stream IP application off of the EIU. No IP traffic will flow between the Compact Core and the down-stream IP application.

Figure 7 TDM LAN Integrated With Packet LAN



155.2.2.5.13 ICM connectivity pre-testing to the CCA

The intent of the pre-testing is to verify TCP connectivity on port 2500 to the CCA IP address. The tests will be performed a few days prior to the night of cutover.

TCP port scan of port 2500 on CCA IP address is used to pre-test the ICM connectivity.

Depending on how the ICM system is connected to the central office, additional rules on firewall(s) may be required to support ICM connectivity to the new core. In order to derisk ICM connectivity issues on the Night of Cutover, connectivity pre-testing should be performed from both:

1. Central Office site, on the TDM lan.

2. Customer ICM site(s)

Figure 8, "ICM connectivity Pre-testing" shows some example ICM systems connected to the Central office, and the connectivity testing done from each site.

TCP Port 2500 test

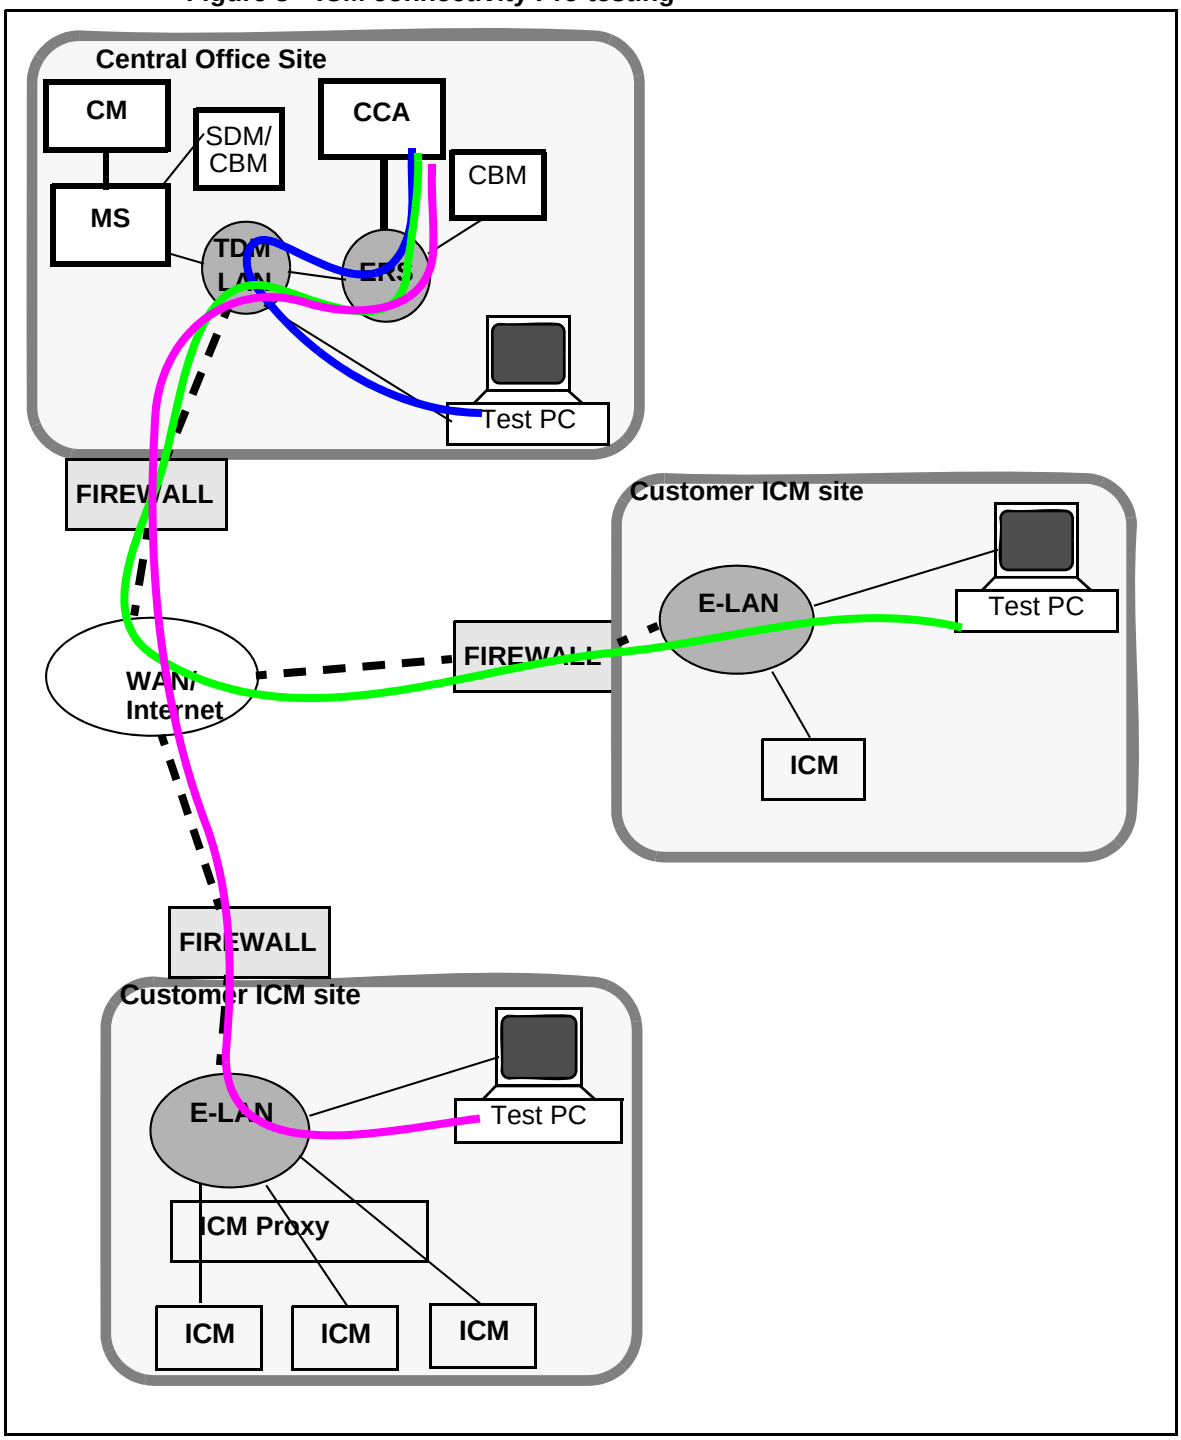
The TCP port test tests only TCP connectivity to port 2500 (port used by ICM/ SCAI); it does not validate any SCAI functionality in the SOS image, and does not require any special datafill in the SOS image, thus this is a much simpler test.

A port scan tool can be used to test the responsiveness of port 2500 on the CCA IP address. The desired response is that port 2500 is open on the CCA ip address.

Alternately, telnet can be used to attempt to test the connectivity to port 2500. (e.g. telnet <cca_ip_address> 2500)
Note that the desired response is that the telnet connection is rejected (since the CCA is not setup to support telnet on port 2500). If the request times out, this indicates that there is no connectivity to the CCA IP address.

Given the simplicity of the TCP port 2500 tests, and the easy availability of the software on the test PCs, the port scan or the telnet test is used to pre-test the ICM connectivity, at least for testing from the ICM customer site.

Figure 8 ICM connectivity Pre-testing



155.2.2.5.14 Transfer and Conversion of Switch data from CM to Succession CS-2000 Compact

This phase includes:

- Make sure that the Billing pretest is completed.
- ManB all the CBM850 applications (appctrl -b all)
- Setup of the MATECORELINK in the data transfer configuration (1 link to Compact).
- VOLNAMXFR to transfer the volume names from the CM to the Compact.
- VOLALIAS to provide a mapping from CM to Compact volume names.
- SLMXFR to transfer selected files from the CM to the Compact.
- TABXFR to transfer office datafill from the CM image to the compact image.

  Special steps are taken at this point to not transfer any of the office tables from the CM core that contain CM IP address and routing datafill. The following tables are not transferred:

  — IPNETWRK

  — IPHOST

  — IPROUTER

  — IPPROTO

  — IPTHRON

  — RMCONFIG

  The following tables are transferred:

  — ENSITES

  — ENTYPES

  — EXNDINV

- Software Optionality Control (SOC): As per ONP, any SOCs that are available on the active CM core are automatically transferred to the inactive Compact Core (Tables SOCOPT, SOCVAR, SOCFEAT). Any new software optionality control that need to be activated in the Compact Core that are not already active in the CM core, is not covered automatically and will need to be handled manually. [1]

155.2.2.5.15 Switching Activity from CM to Compact

The switching activity phase involves:

- Establishing the Switch of activity CMIC configuration - a second CMIC is toggled to the compact core for a total of 2 links, one from each MS. The MATECORELINK is then re-established on the second CMIC.

[1]SOCs for SMDR and SMDI may need to be handled manually, as SOC for these applications was introduced into Compact Core for these applications in SN04.

- Performing PRESWACT to prepare both cores for the switch of activity, and transfer dynamic data to the Compact.
- Prepare IP applications for cutover. Insure that all IP connections that are established over the EIU are properly disconnected.
  - The NETMAN tool can be used to insure that all IP connections are down.
- Do not run the **StatusCheck** under **bcsupdate; swactci** before the cutover.
- Rts all the applications on the CBM850 (appctrl -r all)
- If DDMS application is configured on CBM850, perform the following steps to bring up the DDMS applications.
  - unpermit the DDMS users on the CCA (e.g. unpermit sdm01)
  - permit the DDMS users on the CCA with default password
  - Bsy & Rts the DDMS applications (**OSS Comms Svcs & OSS and Application Svcs**) on the CBM850
- Make sure that all the SBA schedules are activated on the CBM850. Follow the procedure given in **Appendix section 3.9.6.**
  - If not activated, follow the procedure in **Appendix section 3.9.5** to activate the same.
- Make sure all the application on the CBM850 is InSv state (cbmmtc appl). It might take 10-15 minutes.
- ICM customers shut down their ICM systems and change IP address to CCA IP.
- Performing the NORESTARTCUTOVER to perform the actual switch of activity from the CM to the Compact, and recovery of the office.[1]
- Switching all CODs to the Compact Core.
- ICM customers restart their ICM systems, verify connectivity to the CCA Core, and proceed to test ICM calls.
- Performing office testing to ensure that the new load is running correctly.
- Perform the billing application posttest on CCA and CBM850. Refer **Appendix section 3.9.2** to run the test.
- If downstream is configured on the SDM/CBM800, send the billing files to the downstream. Refer **Appendix section 3.9.3** to transfer the billing files to downstream.
- Bsy and OffL the DS512/OC3 card on the CCA, which is used for connecting the SDM/CBM800.
- Performing POSTSWACT to cleanup after the switch of activity.

[1]As per all ONP's on CM, the applicator should be connected via the modem interface on the IOC and should not be using TELNET to connect to the CM.

- Soak min of 24 hours.

155.2.2.5.16 Cutover Tools Removal

This phase removes the COD devices from the MS links, integrating the NT9X63 OC3 paddleboards into the MS shelf. At this point, the Portable shelf can be removed from service.

Then, the Cutover software tools are removed from the Compact Core.

It is not necessary to remove the software Cutover tools from the CM core, as it will be decommissioned.

155.2.2.5.17 CM Core Decommissioning

This phase results in the CM core and SLM being removed from the CM shelf.

155.2.2.5.18 DMS TDM IP Hardware Decommissioning

This phase results in removal of all the DMS TDM IP hardware from the office and corresponding datafill from the compact image. The steps involved in this are:

- Removal of EIU hardware from the LPP/LIS/FLIS:
  - — Ethernet Interface Paddleboard Card - NT9X85AA,
  - — Ethernet Interface Card - NT9X84AA,
  - — Integrated PBUS and FBUS Card - NTEX22BB
  - — Media Access Unit (MAU) - a commercially available unit,
  - — Attachment unit interface cable.
- Removal of EIU datafill from table LIUINV.

155.2.2.6 Summary of changes to documentation

This section lists the documents used in the SL-100 CM to Compact cutover, and indicates in general the changes required to make documentation suitable for the NA and Intl CM to Compact cutover.

General changes required to multiple documents:

- Change references to MSL-100 product to DMS-100 Family product supported by this cutover procedure.
- Change references from SE06 to (I)SN09 (CM) or (I)SN09FF (Compact).
- References to IMs or other documents within these documents must be changed to refer to the new or changed documents.
- CCA software and tools are no longer delivered on DAT tape - most DAT tapes have been replaced by CD; SOS load comes on DVD.

The new procedures for CBM-850 application testing need to either be inserted at the appropriate points in existing documents, or have new documents created:

- CBM-850 application pre-test: (executed prior to the night of cutover) This could potentially be a new IM document.
- Billing pretest procedure for CCA/CBM850.
- Billing posttest procedure for CCA/CBM850.
- Billing testing Procedure for SDM/CBM800 during the abort. This is required for both the abort (prior and after switch activity)
- Sending the Billing files to downstream.

Table 2 MSL-100 Cutover Documentation

Document	Title	Changes Required
02-0526	SuperNode CM/SLM to Compact Hybrid Cutover Planning Guide	Bringing office hardware to SN06 baseline and upgrade it to supported h/w; s/w baseline to SN06 baseline, then upgrade it to SN09. The cutover will be done from SN09 to SN09FF
02-0872	SNSE CM/SLM to Compact Hybrid Cutover Planning Guide	Bringing office hardware to SN06 baseline and upgrade it to supported h/w; s/w baseline to SN06 baseline, then upgrade it to SN09. The cutover will be done from SN09 to SN09FF
24-1469	Compact Core Software Tools Loading	Need to add additional modules introduced for CM and new scripts to load and unload the modules on CM. Need to add the billing pre-test modules introduced for CCA. These tools need to be transferred only if billing pre-test is required.
24-0879	SLM Data Transfer for SNSE/CM to Compact Core Upgrades	
24-1471	SLM Data Transfer for SN/CM to Compact Core Upgrades	
24-0877	MS Boot Testing for SNSE CM/SLM to Compact Core Upgrades	
24-1470	MS Boot Testing for SN/CM to Compact Core Upgrades	

Document	Title	Changes Required
78-0534	COD Integration for SN/CM to Compact Core Upgrades	
78-0538	COD De-Integration for SN/CM to Compact Core Upgrades	
78-0874	COD Integration for SNSE/CM to Compact Core Upgrades	
78-0878	COD Deintegration for SNSE/CM to Compact Core Upgrades	
24-1626	Patch-Current S/W Loading for SN/ SNSE CM/SLM to Compact Core Upgrades	
78-0539	SN/CM to Compact Core Cutover	
78-0873	SNSE/CM to Compact Core Cutover	
78-0873	SuperNode MS System Upgrade for XA-CORE	
65-6131	SuperNode SE: MS System Upgrade for XA-CORE	
78-1466	Portable XA Installation/Removal for Compact Core Hybrid	
30-1473	Clean Up for CM to Compact Core Hybrid Upgrades	
24-0971	CS2000 Compact Call Agent/ STORM Software Installation and Commissioning	Not related to cutover, although used in installation/commissioning of CCA – should be no change.
555-4001-213	Meridian SL-100 SN/SNSE CM to Compact Core upgrade Method of Procedure	- Remove the DPP/BMC billing references. - Remove references to SMDR billing over EIU. - Remove the step and procedure used to perform the STATUSCHECK on CM core after the preswact and before the norestartcutover.

155.2.3 Cutover Aborts

Aborts of the procedure are provided for two main scenarios:

- Prior to switching activity to the Compact.
  Generally, the abort involves stopping the process, and switching all CODs back to the CM core.
  Make sure that all the applications on SDM/CBM800 becomes in-service after the abort.
  Perform the billing testing on SDM/CBM800. Refer **Appendix section 3.9.4** to test the billing on SDM/CBM800.
  If applications are in-service (appctrl -q all) in CBM850, bsy all the applications (appctrl -b all).

- After switching activity to the Compact.
  Once the switch of activity has occurred, up to the point where the new load has been accepted, abort back to the CM is possible using the following method:
  - If necessary, migrate SS7 links from USP-Compact back to FLIS.
  - Switch all CODs back to the CM side.
  - Perform a COREGOACTIVE command from the XARETRO CI on the CI@CM-RTIF.
  - Perform a COREGOINACTIVE command on the compact core.
  - For offices which have ICM, the core address on each of the ICM systems (or ICM proxy as appropriate) will need to be changed back to the old CM core IP address. Note that this requires coordination with the ICM customer(s) who have the ICM systems on their site(s).
  - Make sure that all the applications on SDM/CBM800 becomes in-service after the abort. It might take up to 15 minutes.
  - Perform the billing testing on SDM/CBM800. Refer **Appendix section 3.9.4** to test the billing on SDM/CBM800.
  - If downstream is configured and billing records are collected in the CBM850, send the billing files to the downstream. Refer **Appendix section 3.9.3** to transfer the billing files to downstream.
  - Bsy all the application on the CBM850 (appctrl -b all)

It is recommended that the office undergo a data freeze during the acceptance period, as Journal files from the compact core will not be applicable to the CM core.

Once the CODs have been removed, abort is no longer possible.

155.3 Hardware Requirements or Dependencies

The following table lists hardware needed for the core cutover procedure.

Table 3 Cutover Hardware Requirements

Part Number	Title/Description
DSLX22AA	CMIC DS-512 to OC-3 Switchbox (SuperNode)
DSLX22BA	CMIC DS-512 to OC-3 Switchbox (SuperNodeSE)
NTLX01DA	Portable XA-Core

The following table provides a description of the MS baseline requirements for support of the CM to Compact Core Cutovers. Where indicated the components may be upgraded as part of the procedure, otherwise the baseline requirements must be met prior to beginning the process.

Table 4 MS Hardware Baseline (MS):

PEC	PRODUCT DESCRIPTION	COMMENTS
NT9X13DG Rel 01+	MS Processor (16 Meg.)	Upgraded SN MS/LMS CPU (NT9X13DD/DC/DB*)
NT9X17AD Rel 06+	MS 4-PORT PCP	Upgraded NT9X17AA - Upgraded ONLY for CMIC links
NT9X53AD Rel 05+	MS Clock Card	Needed to I/F with NTLX44AA
NT9X63 AB Rel 01+	OC3 2-PORT Paddleboard (with E3MLIC)	Replaces NT9X20AA/ NT9X62AB. Upgraded during procedure.
9X15AA Rel 50+	Mapper card	
* Currently deployed standard product.		

SDM Hardware Baseline:
Please refer to the “SDM Hardware Baseline” document under the following link for the SN09 SDM hardware baseline information.

http://livelink-ott.ca.nortel.com/livelink/livelink.exe?func=ll&objId=7908447&objAction=browse&sort=name

CBM800/CBM850 Hardware Baseline:
Please refer to the “CBM Product Specification 22/09” document under the following link for the SN09 CBM800 hardware baseline information.

http://livelink-ott.ca.nortel.com/livelink/livelink.exe?func=ll&objId=11892249&objAction=browse&sort=name

Please refer to the “CBM Product Specification” document under the following link for the SN09FF CBM850 hardware baseline information.

http://livelink-ott.ca.nortel.com/livelink/livelink.exe/fetch/6809740/13197707/7331141/7330811/12172432/CBM_Product_Specification_23_9.1?nodeid=12172204&vernum=0

155.4 Software Requirements or Dependencies

SDM/CBM800 & CM Software Baseline:

- SDM/CBM800 running in SN09 software baseline. All the SN09 patches need to be applied on the SDM/CBM800 prior to the cutover.
- CM running in SN09 software baseline. All the SN09 core patches need to be applied on the CM prior to the cutover.

CBM850, CCA and Cutover tools Requirement:

- (I)SN09FF Compact Call Agent software baseline.
- CM cutover tools on SLM tape.
- Compact-Core Cutover tools on CDs.
- SSPFS CDs for the CBM850.
- SN09FF CDs for the CBM850.
- SN09FF Compact-Core platform (LINUX) image and MC (Message Controller) image on CDs.
- SAM21 Load on CD.
- SN09FF nodata Compact-Core Application (SOS) and MS images on DVD.

155.5 Limitations and restrictions

This activity supports the cutover of CM core to Compact TDM/Hybrid Core.

- Only offices containing ENET are supported. JNET is not supported.
- Offices containing SDM/CBM800 are supported in the FROM configuration. The SDM/CBM800 is converted to a CBM850 during the cutover.
- Only the ICM IP communication based application is supported during the cutover:
  Other IP based applications are not supported over the cutover, although in most cases the application may be restarted after the cutover using the new core IP address.
- Both Supernode and Supernode SE are supported.

- SN70EM and SNSE70EM CMs are supported. SN50, SN60 or previous CMs are not supported
- Only common applications between SDM/CBM800 and CBM850 are supported during the cutover.

155.6 Interactions

This activity interacts with activity A00012766 for the SDM/CBM conversion.

155.7 Glossary

Term	Description
SNSE	SuperNode Size Enhanced
CBM	Core and Billing Manager
COD	Cut Over Devices
3PC	Third-Party Core, now called CS-2000 Compact.
SN	SuperNode
CCA	Compact Call Agent
ONP	One Night Procedure
CM	Compact Module
SDM	Supernode Data Manager
SBA	Supernode Billing Application

155.8 Reference Documents

Document	Title/Description
MOP 555-4001-213	Meridian SL-100 SN/SNSE CM to Compact Core upgrade MOP

155.9 Appendix

155.9.1 Billing Pretest: Validating Billing Normal & Backup modes

Billing testing will be performed for the SMDR, BC and CDR250 billing records on the Compact Core.

CBM850 setup:
- On the CBM850 verify that TASL and SBA are InSv
  -- From the CBM850: cbmmtc appl

- Verify that the billing stream AMA on the CBM is Active
billmtc
CONFSTRM
list ama

Generate Billing records On Compact Core for AMA stream:
Load the *crsgen* tool on CCA (available as part of the cutover tools)
ca_map> load crsgenui
ca_map> load crsgenp
ca_map> load crsgenci
ca_map> load bcrugeni

crsgen ama setrate 200
crsgen ama start
wait for 1 minute
crsgen ama stop

Generate Billing records On Compact Core for OCC stream:
cdrtst
cdrcrank 10 8 10

Verify the billing for AMA streams:
Verify the CBM850 setup
From the steps above, Start generating billing records using **crsgen**

/cbmdata/00/billing/ama/open> query
AMA:
PrimarySubStream: InSv
Number of Records in Open Files: 1485
ClosedNotSent Files Available: 0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
Date and time unavailable.

/cbmdata/00/billing/ama/open> closec ama
Closed 020001.030002.00001.01.2

/cbmdata/00/billing/ama/open> query
AMA:
PrimarySubStream: InSv
Number of Records in Open Files: 0
ClosedNotSent Files Available: 1
Records within the ClosedNotSent files: 1600

Date of Last File Sent:
Date and time unavailable.

If downstream is configured on CBM850,
Send billing files downstream from CBM850:
billmtc
filesys
sendfile ama
- Verify that the downstream is receiving the file.
Note: This billing file will have the dummy records so, this file should not be processed for any billing purpose on the downstream system. Also, cleanup the dummy billing files from the downstream.

To verify Billing in backup mode, do the following:
From the CBM “cbmmtc” manbusy SBA
>cbmmtc appl
>bsy <SBA appl number>

Take a snapshot on Compact core logical backup volume:

>diskut
>lv
>lf <backup volumes for the ama stream>

- Make sure that there no backup files in all the configured backup volumes for the ama stream.

From the steps above, Start generating billing records using **crsgen**

Verify on Compact core that the logical backup volume is receiving billing file:

>diskut
>lv
>lf <configured volumes>

Those logical volumes should have incremental backup files.

To verify Billing in backup mode can recover do the following:

From the CBM “cbmmtc” manbusy SBA
>cbmmtc appl
>rts <SBA appl number>

On the Core, go to the map level: *mapci;mtc;appl;sdmbil;post ama*

The ama billing state should change automatically to rcvry and then into InSv

```
      MS    IOD    Net     PM     CCS     Lns    Trks    Ext    APPL
     MSpair AMA  B   .      .      .      .      ...   1Crit   .
      *C*    *C*                                        *C*

12
13 Status
14 Query
15
16
17 Audit
18
  OPERATOR
```

Note: Make sure that you are receiving the amount of billing files that were on the core (SCA). The amount of files generated from the tool should match the amount received on the CBM when billing recovered from backup mode.

Unload the crsgen tool from Compact core:

```
ca_map> unload bcrugeni
ca_map> unload crsgenci
ca_map> unload crsgenp
ca_map> unload crsgenui
```

Verify the billing for OCC streams:
To verify the CDR250 billing format, repeat the above steps for the OCC stream.

Billing cleanup to be ready for the cutover:
From “CBMMTC appl” map level, ManBsy SBA
From the unix prompt on the CBM active unit:
>cd /cbmdata/00/billing/ama
/cbmdata/00/billing/ama>ls -lrt (to list everything under the ama directory)
/cbmdata/00/billing/ama> rm -rf * (remove all files and directories under ama directory to cleanup everything)
From “CBMMTC appl” map level, RTS SBA

From the unix prompt on the CBM active unit, verify that all directories got recreated):
/cbmdata/00/billing/ama> ls -lrt (All directories should have been recreated)

Note:
- If AMA stream is tested, Make sure that the crsgen tool is unloaded from the Compact core.
- If downstream is tested, Make sure that the dummy billing files from the downstream is cleaned up.

WARNING
During the billing pre-test on CCA, the following swerrs may be observed. Please ignore the swerrs only during billing pre-test.

```
CSNNC09BS     SWER    DEC07 15:24:58 0700

155.9.2 CBM850 Billing Posttest

This testing will be performed immediately after the *norestartcutover* to make sure billing records are transferred to CBM850 from CCA as well as to downstream from CBM850.

Verify the billing on CBM850 for configured streams:
Make sure that the SBA application is in-service in CBM850 (cbmmtc appl).

Run the following command to verify the billing record collection in cbm850:
query
AMA:
PrimarySubStream: InSv
Number of Records in Open Files: 9800
ClosedNotSent Files Available: 0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
Date and time unavailable.

OCC:
PrimarySubStream: InSv
Number of Records in Open Files: 106
ClosedNotSent Files Available: 0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
Date and time unavailable.

Run the query command again, if there are calls processed on the core, the number of records will increase for the streams.
#query

AMA:
PrimarySubStream: InSv
Number of Records in Open Files: 23912
ClosedNotSent Files Available: 0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
Date and time unavailable.

OCC:
PrimarySubStream: InSv
Number of Records in Open Files: 420
ClosedNotSent Files Available: 0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
Date and time unavailable.

If, downstream is configured, verify that the billing files are transferred to the downstream as per the configured schedules.

155.9.3 Sending billing files to Downstream

Procedure to send the unsent billing files from SDM/CBM800/CBM850 to the downstream.

```
# closec ama
billmtc
filesys
sendfile ama
```

- Repeat the above steps for all the configured streams.
- Verify that the downstream is received the billing file.

155.9.4 SDM/CBM800 Cutover abort Billing test

This testing will be performed immediately after the fallback to make sure billing records are transferred to SDM/CBM800 from SN/SNSE CM as well as to downstream from SDM/CBM800.

Make sure that the SBA application is in-service in SDM/CBM800.

Run the following command to verify the billing record collection in SDM/CBM800:

```
# query
AMA:
    PrimarySubStream:                   InSv
    Number of Records in Open Files:    2058
    ClosedNotSent Files Available:      0
    Records within the ClosedNotSent files: 0
    Date of Last File Sent:
        Fri Nov  4 10:27:11 2005

OCC:
    PrimarySubStream:                   InSv
    Number of Records in Open Files:    212
    ClosedNotSent Files Available:      0
    Records within the ClosedNotSent files: 0
    Date of Last File Sent:
        Fri Nov  4 10:28:42 2005
```

Run the query command again, if there are calls processed on the core, the number of records will increase for the streams.

```
#query

AMA:
    PrimarySubStream:                   InSv
    Number of Records in Open Files:    7154
    ClosedNotSent Files Available:      0
    Records within the ClosedNotSent files: 0
    Date of Last File Sent:
        Fri Nov  4 10:27:11 2005

OCC:
    PrimarySubStream:                   InSv
```

```
Number of Records in Open Files:        762
ClosedNotSent Files Available:          0
Records within the ClosedNotSent files: 0
Date of Last File Sent:
      Fri Nov  4 10:28:42 2005
```

If downstream is configured on the SDM/CBM800, verify that the billing files are transferred to downstream as per the schedules configured.

155.9.5 Activating the SBA Schedules on CBM850

Make sure that the SBA application is in-service in CBM850.

If there are any schedules configured for SBA, then follow the steps below.

Execute the following commands on CBM850 to activate the SBA schedules.

```
# billmtc
SCHEDULE
Change ama

File_Format_Type       : 'DNS'
Destination            : 'AMA1'
Protocol               : 'FTPW'
Primary_Destination    : '47.129.82.27'
Primary_Port           : '21'
Alternate_Destination  : '47.129.82.27'
Alternate_Port         : '21'
Start_Time             : '00:00'
Stop_Time              : '23:59'
Interval               : '120'
Remote_Storage_Directory: '/home/ksamy/CBMSBA'
Remote_Login           : 'ksamy'
Remote_Password        : '******'
Maximum_Retries        : '3'
Retry_Wait_Time        : '1'
File_Extension         : ''
Field_Separator        : '.'
Active                 : 'No'

Enter the field name to be changed. Stream, File_Format_Type and
Destination cannot be changed.

Enter 'All' to be prompted for all field names.
Press Enter to accept 'All'.
Enter Field_Name: Active

WARNING: Billing files associated with this tuple will not transfer
downstream when Active is set to No.
```

Valid active values are {'No', 'n', 'Yes', 'y'}.
Press Enter to accept 'No'.
Enter Active: **Yes**

Stream : 'AMA'
File_Format_Type : 'DNS'
Destination : 'AMA1'
Protocol : 'FTPW'
Primary_Destination : '47.129.82.27'
Primary_Port : '21'
Alternate_Destination : '47.129.82.27'
Alternate_Port : '21'
Start_Time : '00:00'
Stop_Time : '23:59'
Interval : '120'
Remote_Storage_Directory: '/home/ksamy/CBMSBA'
Remote_Login : 'ksamy'
Remote_Password : '******'
Maximum_Retries : '3'
Retry_Wait_Time : '1'
File_Extension : ''
Field_Separator : '.'
Active : 'Yes'

Valid actions are {'Save', 'Edit', 'Abort'}.
Press Enter to accept 'Edit'.
Enter Action: **Save**

Schedule tuple changed.

Press Return to Continue.

Repeat the above steps for all the configured schedules.

Activating the RTB Schedules:

If RTB is configured on CBM850, follow the below steps to activate.

billmtc
SCHEDULE
RTB

bsy OCC DIRP OCCCLNT
rts OCC DIRP OCCCLNT
Query OCC

Stream : OCC
Destination list :

DIRP OCCCLNT **INSV**

Repeat the above steps for all the RTB configurations.

155.9.6 Checking the SBA Schedule status on CBM850

Make sure that the SBA application is in-service in CBM850.

If there are any schedules configured for SBA, then follow the steps below.

Run the following commands on CBM850 to get the status of each configured schedules on CBM850.

billmtc
SCHEDULE
list OCC

Stream : 'OCC'
File_Format_Type : 'DIRP'
Destination : 'OCC1'
Protocol : 'RFTPW'
Primary_Destination : '47.129.82.27'
Primary_Port : '21'
Alternate_Destination : '47.129.82.27'
Alternate_Port : '21'
Start_Time : '00:00'
Stop_Time : '23:59'
Interval : '5'
Remote_Storage_Directory: '/home/ksamy/CBMRTB'
Remote_Login : 'ksamy'
Remote_Password : '******'
Maximum_Retries : '3'
Retry_Wait_Time : '1'
File_Extension : ''
Field_Separator : '.'
Active : 'Yes'
Press Enter to continue ('Abort' quits)...

Make sure that the Active field is set to “Yes”.

Repeat the list command for all the configured streams and make sure that the Active field is set to “Yes” for all of them.

Checking the RTB status:

```
# billmtc
SCHEDULE
RTB
Query OCC

Stream : OCC
Destination list :
-------------------------------------------------
DIRP OCCCLNT                    INSV
```

Make sure that the RTB status is INSV.

Repeat the above steps for all the configured RTB tuples.

156: Functional Description (FN) A00012478

156.1 Feature name and Feature ID

A00012478 - Compact Call Agent: Geo Support for GigE

This feature supports GigE interface for sparing or synchronizing data between the two MCG905-270 CCAs for both Geo and non-Geo configurations.

156.2 Description

This feature enables synchronization of data between two Compact Call Agent (CCA) blades over a Gigabit Ethernet link. The current design uses Fiber Channel (FC) for keeping data synchronized. This feature will provide an additional option of synchronization over Gigabit Ethernet (GigE) depending on the customers' needs.

GigE is an ethernet technology that provides an alternative for high-speed data transmission (1 gigabit per second) to achieve memory synchronization between active and inactive CCA. The principal benefits of GigE are:

- It provides a low cost, reliable and fast data transmission solution. GigE is based on the Ethernet protocol and Ethernet standards are the most deployed network backbone solution.
- It is scalable and upgradable. It may be possible to upgrade data synchronization over GigE to 10 GigE in the future.

Other benefits include:

- A GigE link has a lower cost to provision and maintain than a Fiber Channel link for Geo applications. For customers who do not own optical transport between geo sites, GigE has a lower lease cost then Fiber Channel.
- It is expected that a GigE link for Geo applications will allow greater distances between sites to be supported.

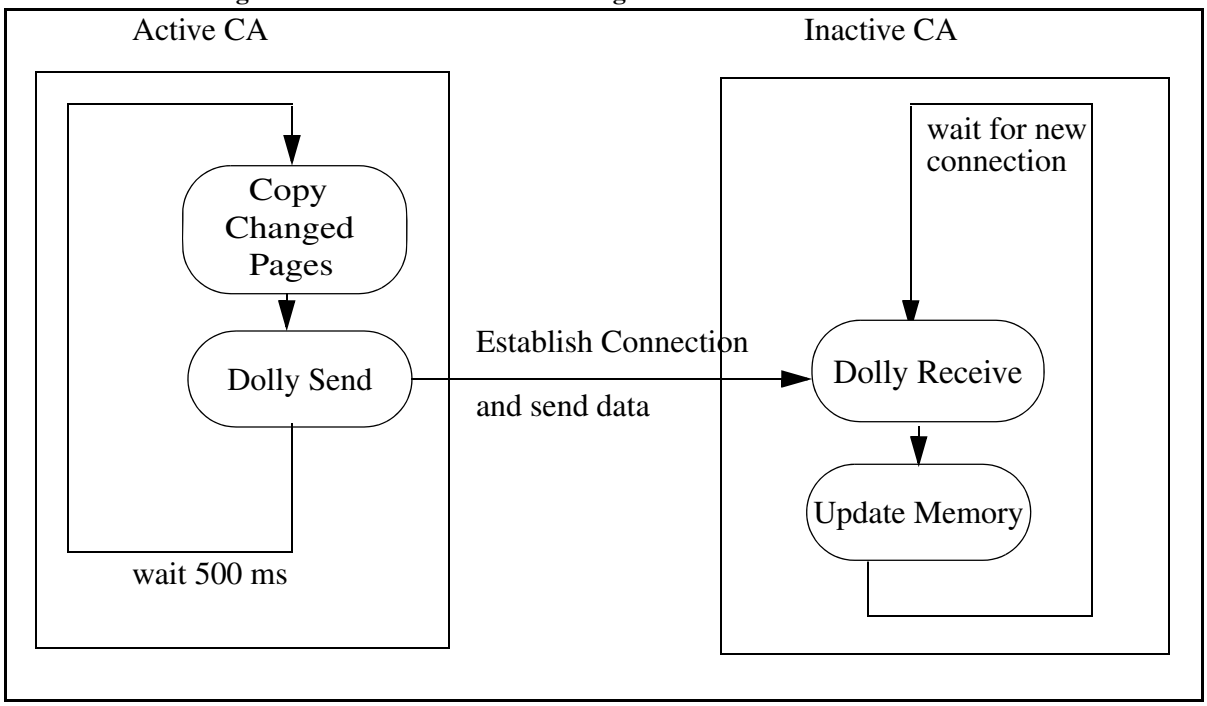
The desired behavior of this feature is to provide an ethernet transport option between two MCPN905-based CCA cards. The MCPN765-based CCA cards do not support the GigE ports and hence will continue to use Fiber Channel.

This feature will provide high synchronization bandwidth for the Dolly process. Dolly is a linux process running on both the active and inactive CCA. The instance of Dolly running on the active CCA is responsible for sending the "dirty" or "changed" memory pages to the inactive CCA. The instance of

Dolly running on the inactive CCA is responsible for receiving those changed pages and passing them to PEEL to update memory [Figure 1].

All changed pages are collected and copied into a buffer on the active CCA every 500 milliseconds. The Dolly process running on the active CCA will establish connection over the GigE link with the Dolly process running on the inactive CCA. Once the connection is established, data transmission will start. Any packet loss will be retransmitted to ensure that the inactive does not have a corrupt image due to loss of information. Upon completion of data transmission, the inactive CCA will copy the received data into memory and wait for the next new connection.

Figure 1 Functional Behavior Diagram



- This feature will provide an in-service method to change the FC connection to GigE (and vice-versa) for both Geo and non-Geo configurations with MCPN905-based CCA.
- Support to select either FC or GigE will be provided by the SAM21 Element Manager GUI. The work is documented in feat.A00012581.
  - — The EM GUI will have a separate Sparing Link Type tab to allow selection of either Fiber Channel or Gigabit Ethernet link for sparing or data synchronization between the CCA cards.

— Once the link selection has been made through the EM GUI, that information will be written in the *"extrainfo"* file on the configured Bootp server.

- The MCPN905-based software load will have support for both FC and GigE links between the CCA cards and it will be up to the customer to choose either of the two links (FC, only if they have FC PMC) but not both at the same time.
- This feature shall continue to support the FC links for MCPN765-based Compact Call Agent cards for both Geo and non-Geo configurations.
- For both Geo and non-Geo configurations, a new configuration path supported for upgrade will be

  — from MCPN905-based CCA with FiberChannel set up as synchronization link to MCPN905-based CCA with GigE set up as synchronization link; and vice-versa

156.2.1 Reference Configuration

The Gigabit Ethernet port of the PIM11 on the PrPMC815 card will be used for synchronizing data between the Call Agent cards.

The Fiber Channel connection will remain configurable as it is today, whenever the Fiber Channel hardware and driver are present.

156.2.1.1 Non-Geographic Survivability Mode Configuration

On a standard CS2000-Compact with MCPN905 (NTRX51HZ) CCA cards synchronization of data between the CCA units will be done over a direct and dedicated Gigabit Ethernet link (1000BaseT connection). This will be a point-to-point connection. An example is shown in Figure 2.

156.2.1.2 Geographic Survivability Mode Configuration

- On a Geographically Survivable CS2000-Compact with MCPN905 (NTRX51HZ) CCA cards synchronization of data between the two CCA units will be done via the CS-LAN router. An example is shown in Figure 2, using ERS 8600.
- Configuration of CCA interactions with the local CS-LAN router in each site will be configured on each CCA blade using the setgeoconfig script tool as it is done today. No changes are being made to that procedure.
- The internal architecture of the CS-LAN router should enable building secure VLANs. When port-based VLANs are configured, each VLAN is completely separated from another (broadcast domain). Its unique hardware architecture allows each packet to be analyzed independently of the preceding one. This mode guarantees complete traffic isolation by allowing discarding of untagged traffic on tagged port or tagged traffic on untagged ports. Even if a tagged port receives traffic with a VLAN Id

which identifies a VLAN from another customer configured on the switch, this traffic is completely discarded.

In other words - any traffic within this type of VLAN cannot exit the VLAN, nor can traffic from another VLAN be sent to a port within this VLAN when the IP default gateway is not set. This enables us to use an IP address for the sparing or synchronization of data on the MCPN905-based CCA GigE card without having to advertise it. Traffic will be confined between both CCA cards whether connected directly via a point-to-point fibre or via the CS-LAN router.

- The CS-LAN router must also support JUMBO frames. For example, the 8608SX(E), 8608GT(E), 8608GB(E), 10GE I/O modules and the 2 Gig ports of the 8632TXE board have the ability to forward 9600 (MTU) jumbo frames.
- The CS-LAN router may require an additional module (if it is not already equipped) with 1000BaseT GBIC support for Gigabit Ethernet transmission. For example, the ERS 8600 CS-LAN will require an additional 8608 module quipped with a 1000BaseT GBIC to support GigE. An example of the configuration procedure is shown in Figure 3.
- For configuring the GigE link on any CS-LAN router the engineering guidelines must be followed.
- Please refer to Appendix A for a step by step example in OTT3 about how to configure ERS 8600 to enable sparing over GigE in Geographic Survivable lab.

Figure 2 An example of data synchronization or sparing over GigE on MCPN905 CCA

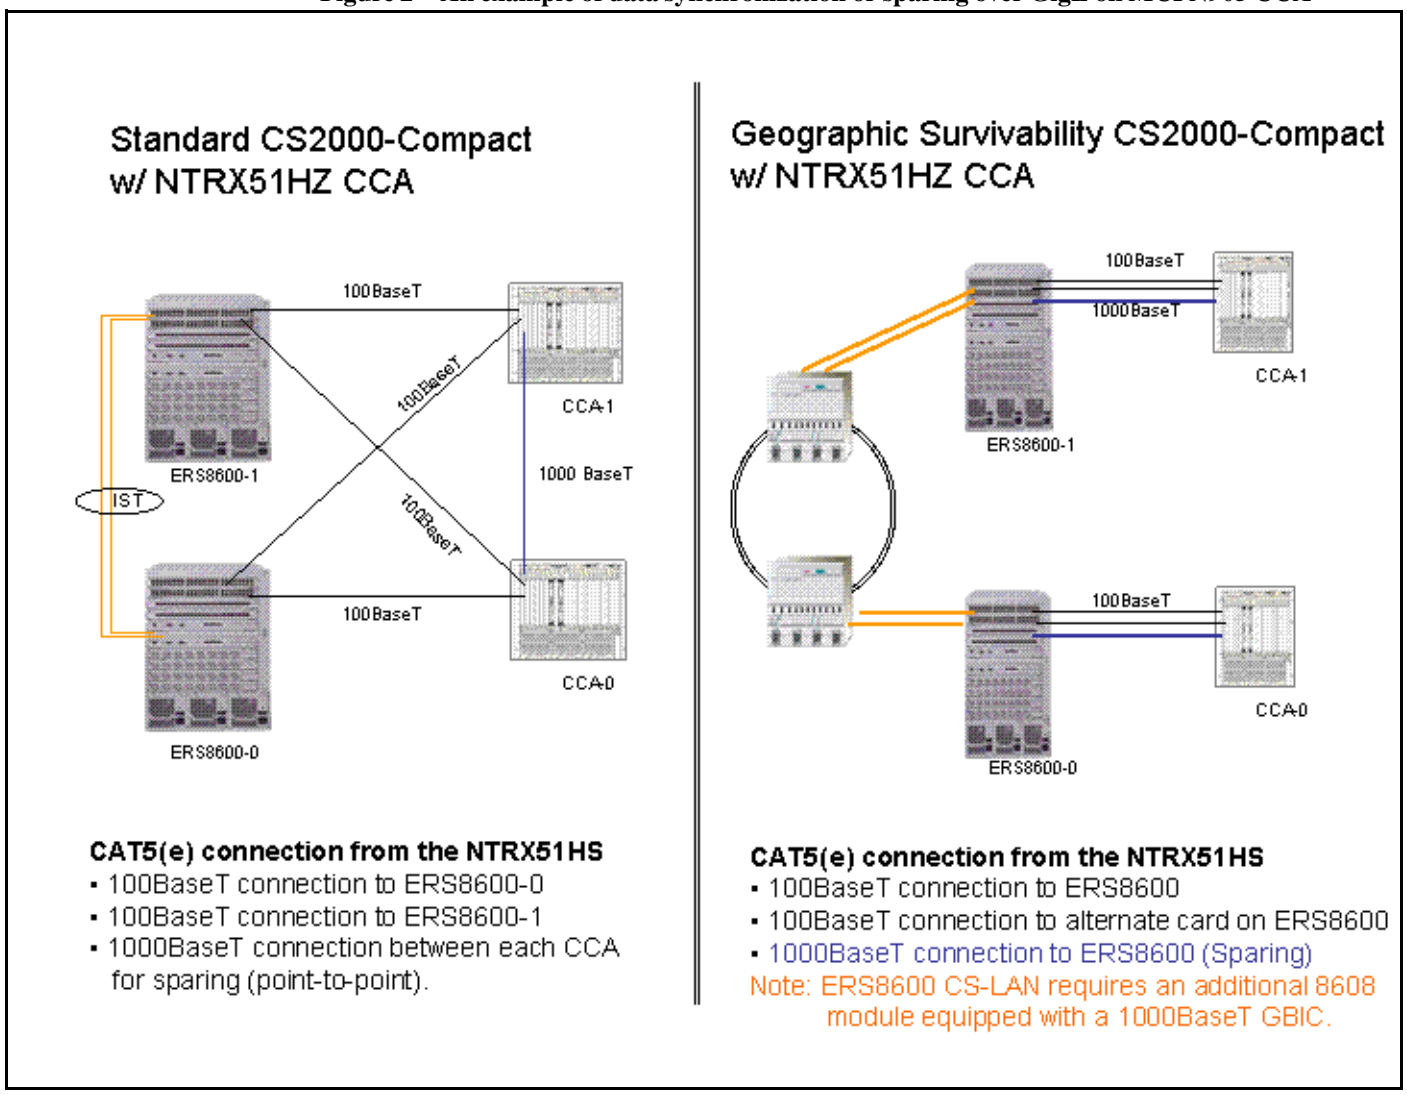


Figure 3 An Example of CSLAN configuration for sparing over GigE on MCPN905 CCA using ERS 8600 router

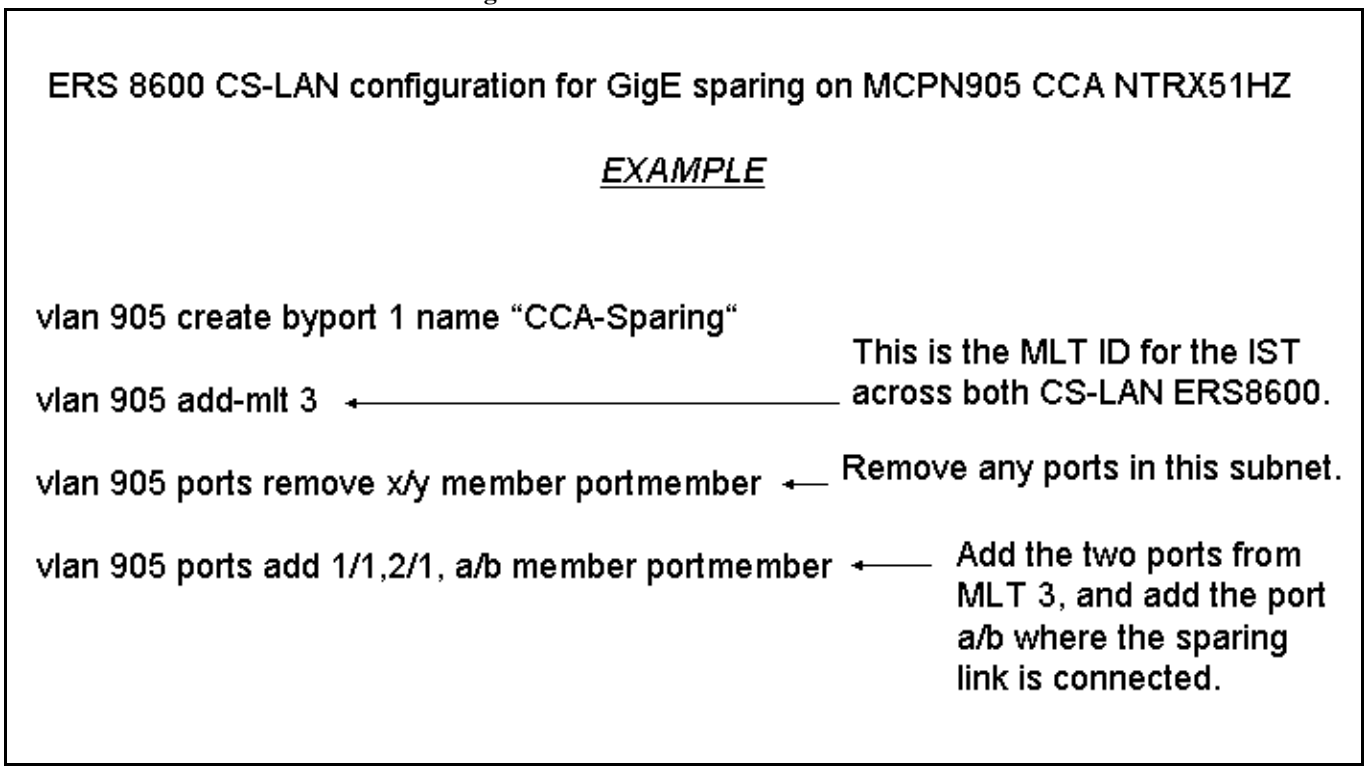

Figure 4 An example of a migration from FC to GigE

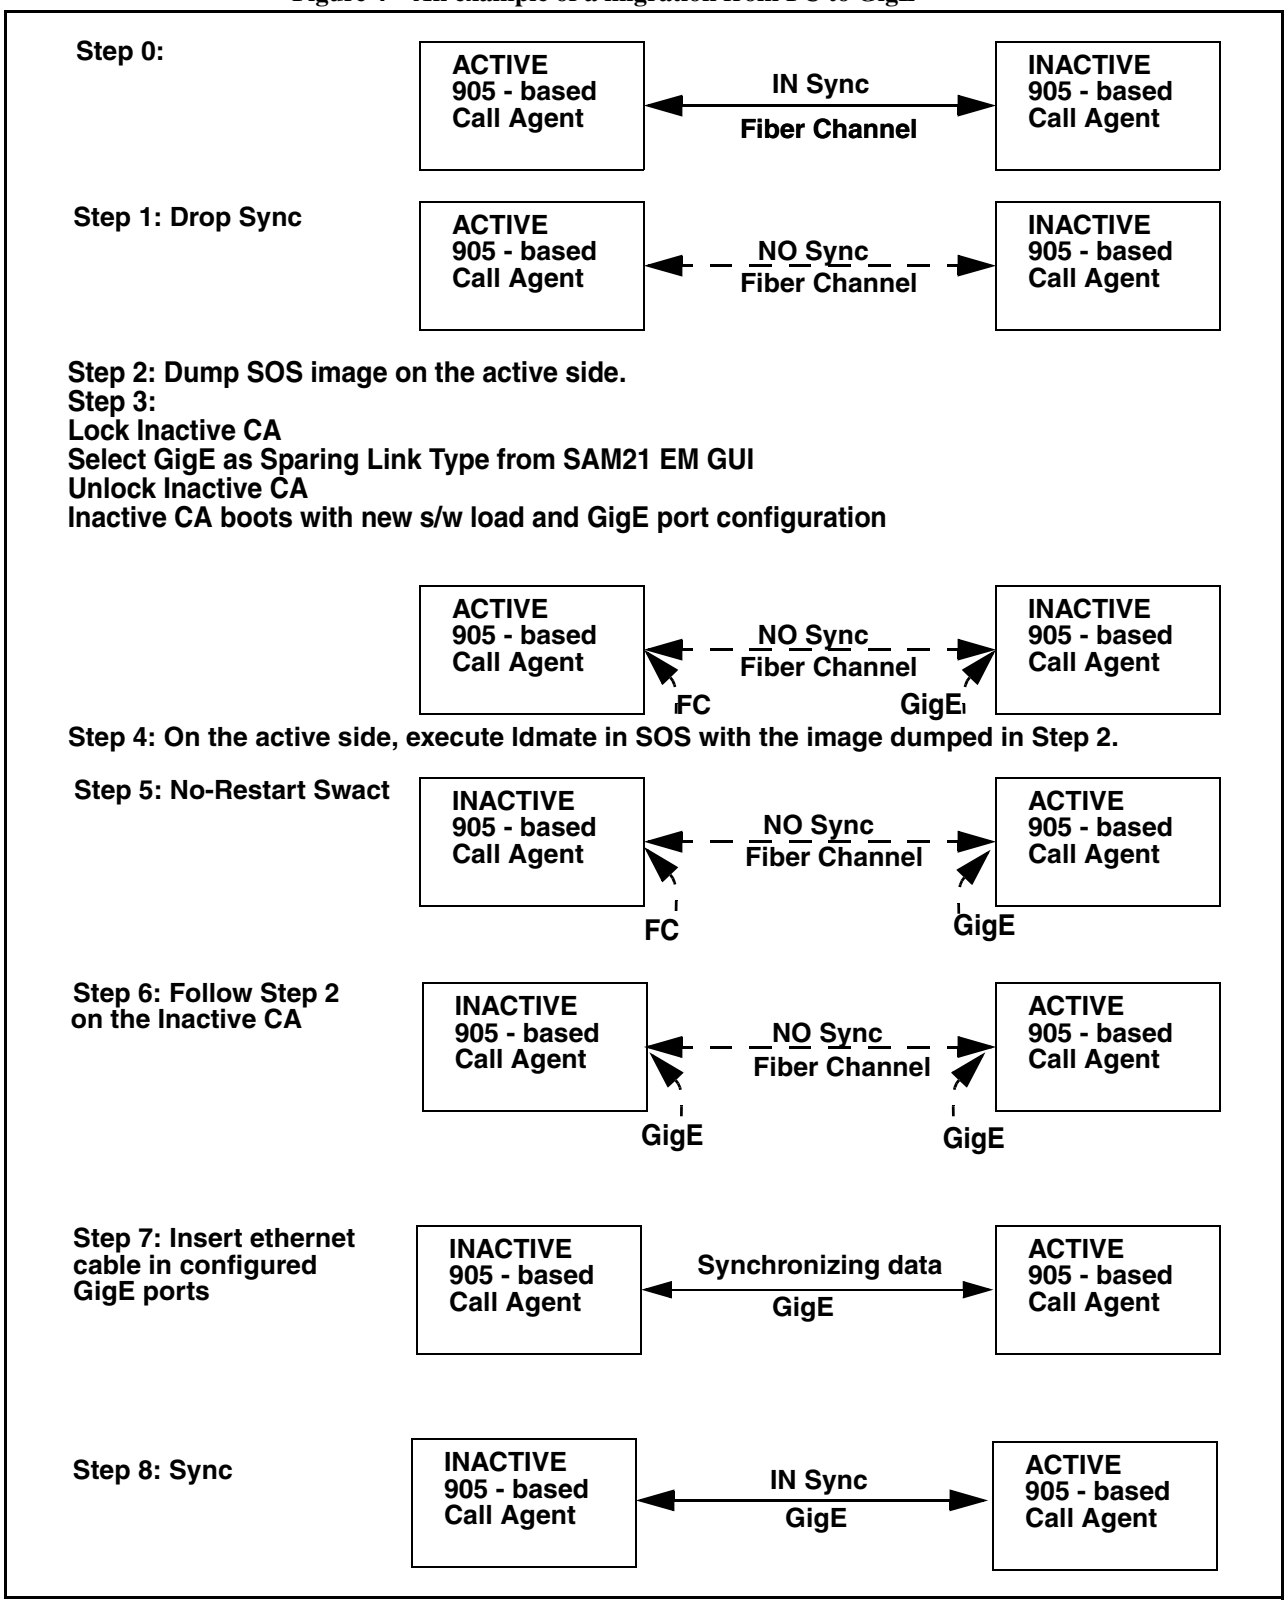
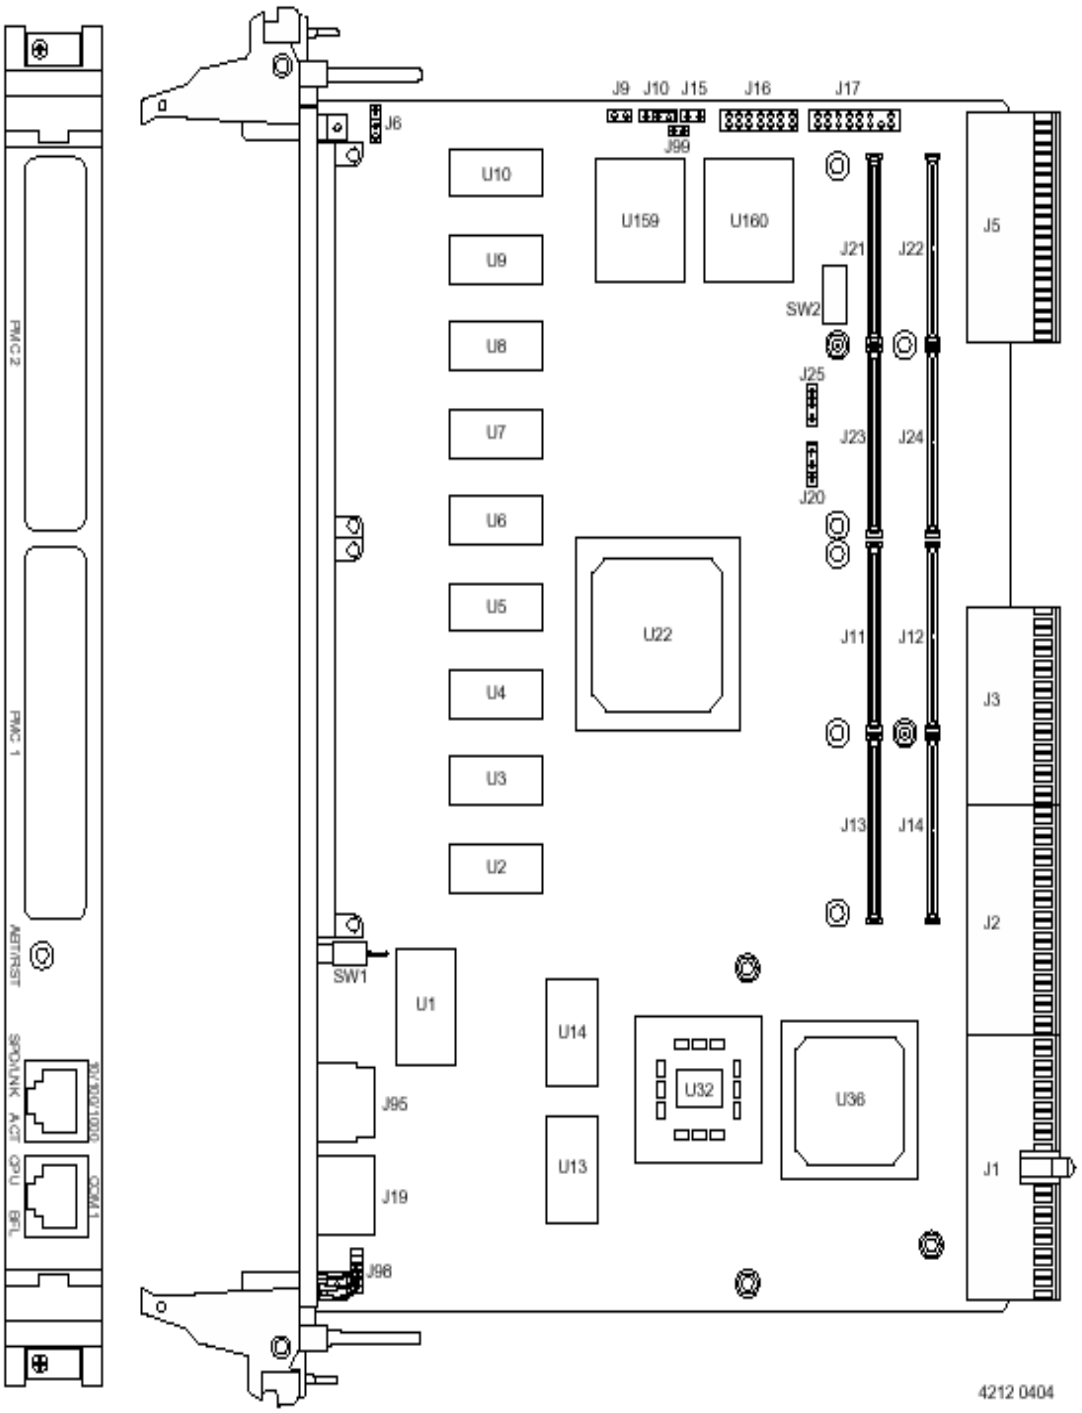


156.2.2 Upgrade scenario

The following upgrade scenarios are for both non-Geo and Geo survivable CS2000-CCA.

156.2.2.1 Hardware and Software upgrade

- In order to use Gigabit Ethernet for data synchronization or sparing, the two CCA blades must be MCPN905-based.
- The two MCPN905-based CCA blades must be equipped with a software load that supports data synchronization over Gigabit Ethernet link.
- The 1000BaseT cable must be inserted in the configured GigE ports on the PrPMC815 before attempting to bring the blades in synchronization.
- For geo configurations, a CS-LAN router is required that supports Gigabit Ethernet.
- It requires specific hardware configuration in order to enable the GigE port on the PrPMC815. On the 905 itself, PMC1 is at the middle of the board (connectors J11 to J14). PMC2 at the top (connectors J21 to J24). On the transition module the PIM for PMC1 is in the middle of the transition module J11. PIM2 is at the top J24.
  For 3pc-905 blade, if both PrPMC815 and FC PMC are present, PrPMC815 must be installed in PMC2 which is at the top of the board and FC PMC must be installed in PMC1 which is in the middle of the board. The rear transition module should be aligned with the position of PrPMC815 so it must be installed in PIM2 which is at the top of the board. If only PrPMC815 is present, PrPMC815 and rear transition module must be installed at the same position as described above.



156.2.2.2 System Impact of Failure Scenarios

In case, there is a fault in the 1000BaseT cable, there will no sparing of data over GigE link. This can cause a potential outage since the switch will be in simplex.

156.2.2.3 Recovery Behavior

If there a problem in the upgrade scenario above, the upgrade can be aborted and the system reverted back to the original configuration.

For example, if a failure happens during an upgrade from a MCPN905-based CCA with synchronization over Fiber Channel to an MCPN905-based CCA with synchronization over GigE, the failure can be corrected by reverting back to using Fiber Channel for synchronization on the MCPN905-based CCA by selecting Fiber Channel as the Sparing Link Type from the SAM21 EM GUI, since the new software load will support FC as well.

156.3 Hardware Requirements or Dependencies

1. For both Geo and non-Geo configurations, a 1000BaseT Gigabit Ethernet cable is required.
2. For Geo-Survivable configurations, the CS-LAN router must be equipped to support Gigabit Ethernet transmissions. For example, the ERS8600 CS-LAN will require an additional 8608 module equipped with a 1000BaseT GBIC.

156.4 Software Requirements or Dependencies

1. SN09FF load (or higher) for Call Agent
2. SN09FF load (or higher) for SAM21 Element Manager GUI

156.5 Limitations and restrictions

- To minimize loss of calls during a migration from FC to GigE, a no-restart swact may be used only
  - — when the CPU utilization is less than 40% and the number of changed pages count is less than 2200,
  - — on the same CCA software load on both CCA blades.

The CPU Utilization can be seen from the tool CAPCI. The number of changed pages can be calculated by checking the SLUTIL field in CAPCI. SLUTIL represents the number of changed pages divided by the maximum sparing link (or synchronization) bandwidth. The maximum sparing link bandwidth is usually set to 6000 pages unless specified otherwise.

$$\text{SLUTIL} = \frac{\text{number of changed pages}}{6000} \times 100$$

156.6 Interactions

Feature A00012581 is directly related to this feature. The SAM21 EM GUI which provides the customer to input the Sparing Link Type is covered under feature A00012581.

156.9 Customer documentation impacts

This feature affects some logs, alarms, and element management as follows:

1. For the custom log changes all the appearnces of "FC" are renamed to "SL", i.e.

   Dec 5 15:35:17 172.16.16.70 logman: CCA335 MAJOR FLT Link Connectivity ^M Unit Number : 1, ACTIVE ^M Description : Link0: SYSB, mateCon: BAD, netCon: BAD; Link0 Mode: FULL_DUPLEX; Link1: INSV, mateCon: OK, netCon: OK; Link1 Mode: FULL_DUPLEX; BLink: INSV, mateCon: OK; **SL**: INSV;

2. Same for the alarm changes, all the appearances of "FC" are renamed to "SL", i.e.

```
Alarm Severity Description
2 CAMtc LnkCon major Link0: INSV, mateCon: OK, netCon: OK;
3 Sys Link0 Mode: FULL_DUPLEX;
4 Con Link1: INSV, mateCon: OK, netCon: OK;
5 Appl Link1 Mode: FULL_DUPLEX;
6 BLink: SYSB, mateCon: BAD;
7 SL: SYSB;
```

3. In CCAMTC, the "FC" for the carrier sparing state is replaced by "SL", i.e.

```
CallAgent SYS CON APPL Unit: 1
C MisM NTP . simplx
M
CoreMtc Jam: Link0: Link1: BLnk: SL: Appl:
0 Quit Unit0 Inact no . Act . Inact . . nosync /waiting
2 CAMtc Unit1 Act no . Act . Inact . . nosync .
```

4. There is a new query util "QuerySL" in CCAMTC slot 16 all mtc levels to query the type is sparing link, i.e.

```
CallAgent SYS CON APPL Unit: 1
C MisM NTP . simplx
M
CoreMtc Jam: Link0: Link1: BLnk: SL: Appl:
0 Quit Unit0 Inact no . Act . Inact . . nosync /waiting
2 CAMtc Unit1 Act no . Act . Inact . . nosync .

11
12
13 LogQuery
14 Alarm
15 QueryIP
16 QuerySL
17 Help
18 Refresh Sparing Link (SL) Type: Gigabit Ethernet
root
```

5. In SAM21 EM, there is a new tab window for 905 card for the customer to choose which sparing link to use, "Fiber Channel" or "Gigbit Ethernet".

157: Functional Description (FN) A00012506

157.1 Feature name and Feature ID

A00012506 - Border Control Point (BCP) Operational Measurement (OM) Enhancements

157.2 Overview

157.2.1 Operational Measurements

Operational measurements (OMs) provide statistical information on the server operations and performances. OMs are represented in terms of groups, which contain registers (counters and gauges) that provide performance-related data. The Management Module (SysMgr) scans OM Group registers at configured intervals. The OM information associated with a selected component is then viewable by administrators in the OM Browser at any selected point in time (corresponding to the launching of the OM Browser). There are two types of OMs: active and holding. Active OMs are displayed as they are reported by the server to the management server/management console. Holding OMs have already been archived to files on the server hosting the active Management Module. The OM scan cycle is configurable using the OAM configuration options available in the System Management Console. OM scan cycles are configured per Network Element (NE). The configured value can be changed via the “Configuration Parameters” (see Figure 1: NE Configuration Parameters), under the “Parm Group: OM” shown in Figure 2: OM Parm Group Configuration Parameters.

Figure 1: NE Configuration Parameters

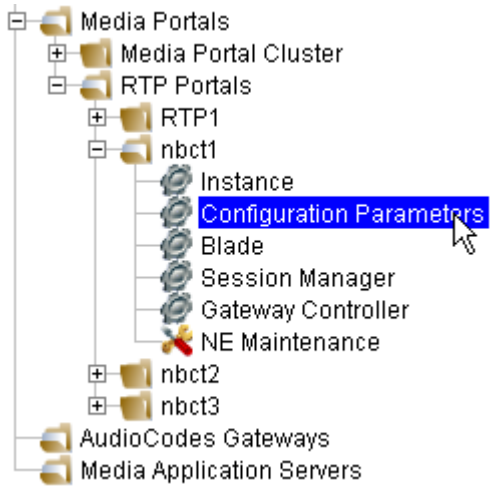

Figure 2: OM Parm Group Configuration Parameters

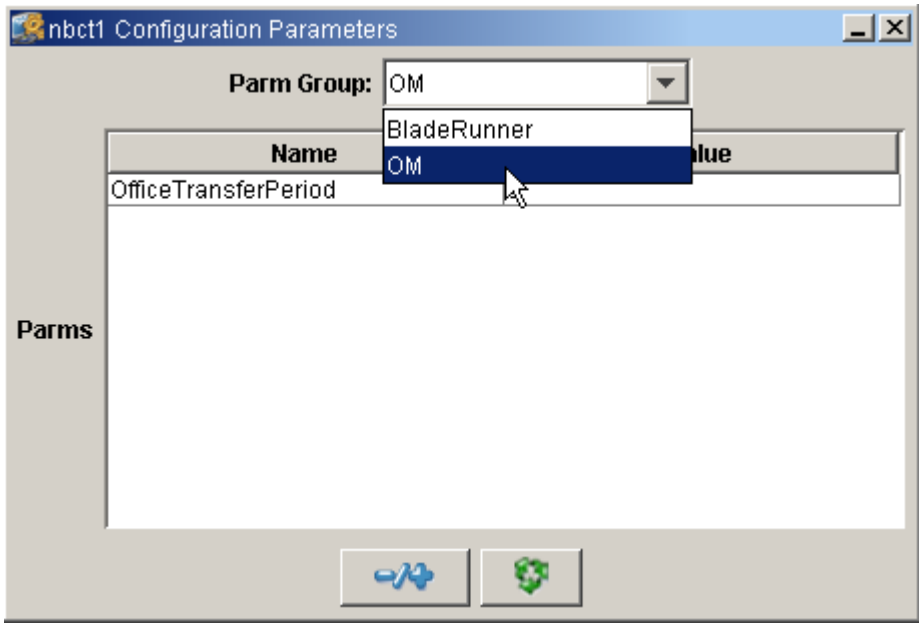
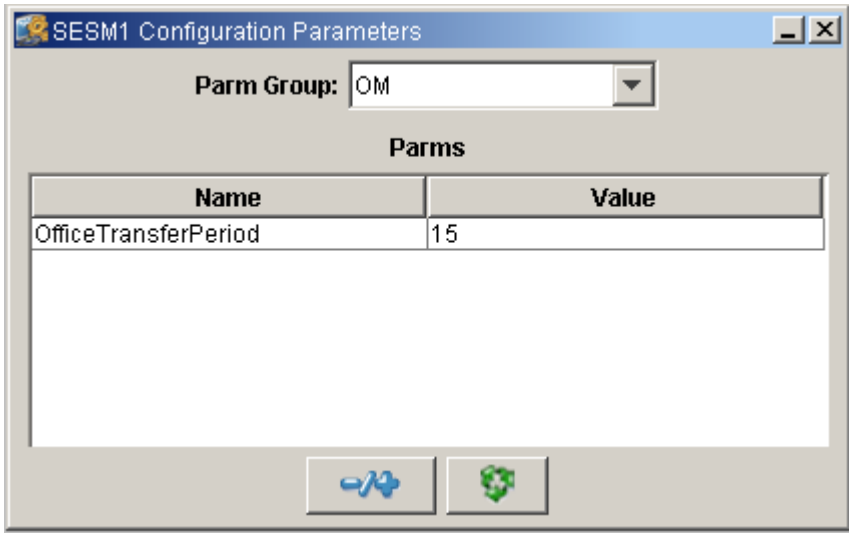


The parameter that controls how often OM's are collected is named "OfficeTransferPeriod" and the value is specified in minutes. Valid values for this parameter are 5, 15, 30 or 60 minutes.

Figure 3: OfficeTransferPeriodConfiguration Parameter



The OM Framework handles pushing OMs collected to IEMS.

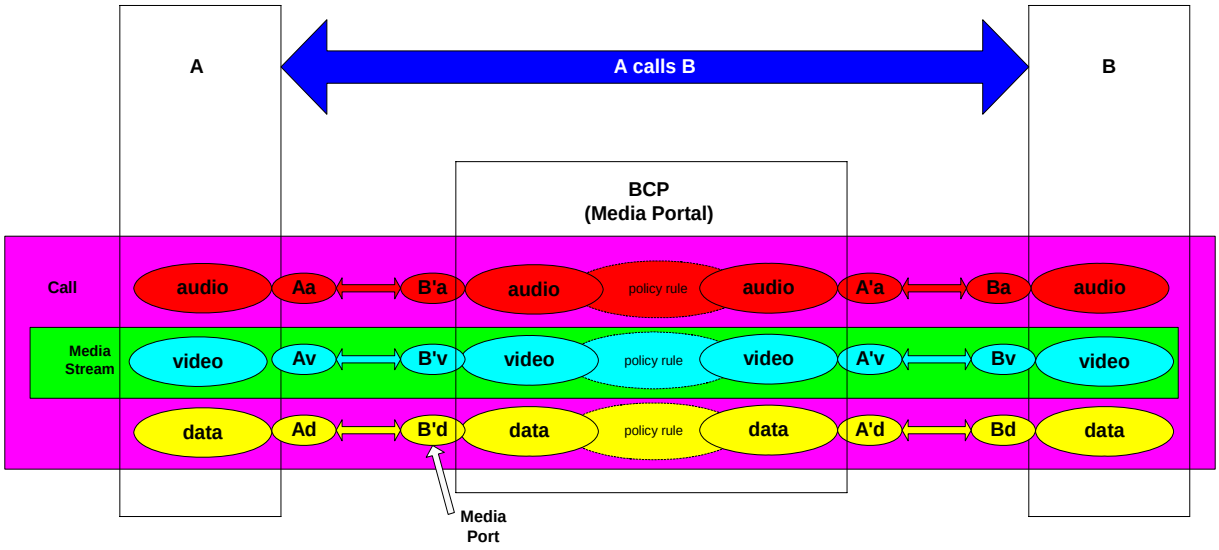
157.2.2 BCP

The BCP was previously referred to as the RTP Media Portal. Renaming existing references to RTP Media Portal is beyond the scope of this feature,

hence; the old terminology is used where needed to maintain consistency with what exists today.

BCP only understands ports and streams. Figure 4: BCP Media Streams shows an example of a basic “A calls B” scenario that involves three media streams. A media stream is successfully created once a policy rule connects two connections on the BCP. In the example shown below, the BCP knows that six ports have been allocated and that three policy rules have been created.

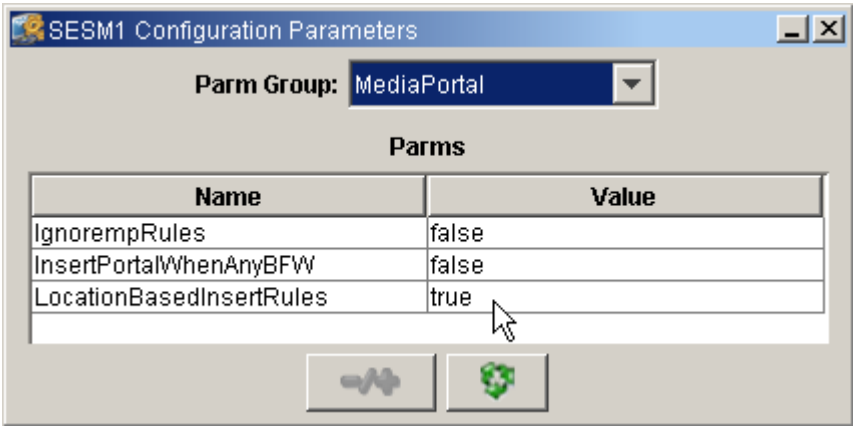
Figure 4: BCP Media Streams



157.2.2.1 BCP Insertion Configuration

The configuration parameters shown in Figure 5: SESM MediaPortal Configuration Parameters may need to be modified depending on network configuration for the Session Manager to insert a BCP for a given call.

Figure 5: SESM MediaPortal Configuration Parameters



IgnorempRules (default setting is false):
If set to true, the SESM would completely ignore BCP insertion rules, meaning the SESM would not insert any BCP to any call in the MCS system. This parameter should only be set to true when there is no BCPs configured in the MCS system. When this parameter is set to true, the settings for "InsertPortalWhenAnyBFW" and "LocationBasedInsertRules" are ignored.

InsertPortalWhenAnyBFW (default setting is false):
This parameter is only used when "LocationBasedInsertRules" is set to false. If "LocationBasedInsertRules" is not enabled, the SESM would use the non-"LocationBasedInsertRules" which is the default setting of the SESM BCP insertion rule. If non-"LocationBasedInsertRules" is used, by default, the SESM does not insert a BCP to a call unless one of the following criteria is met:

- If either or both of originating and terminating clients' domain configurations on the PROV have "AlwaysUseMediaPortal" set to true with this call.
- If either or both of the origination and terminating clients are behind the firewall or NAT (BFW). Basically, with the legacy insertion rule, if there is any BFW client in the call, a BCP should be inserted. However, due to the consideration of the effective usage of BCP resources, it is assumed that if both clients are BFW and in the same domain, most likely they are behind the same firewall or NAT, they should be able to communicate with each other without having to consume any BCP resources. Therefore, in this case, a BCP is not inserted unless the "InsertPortalWhenAnyBFW" is set to true to override the assumption.
- If the call is traversed through two interfaces (public/private), a BCP is inserted.
- If the call is originated from or terminated to a device which is unable to handle media changes, a BCP is inserted.
- If privacy is required for this call, a BCP is inserted.

LocationBasedInsertRules (default setting is false):
This is the enhanced BCP insertion rule that is based on the location infrastructure of the virtual network topology. If this parameter is set to true, the SESM would ignore the legacy BCP insertion rules (e.g. firewall clients, InsertPortalWhenAnyBFW, AlwaysUseMediaPortal domain, etc). By default, the SESM inserts a BCP to every call unless there is a Routability Group provisioned via the Provisioning Module for the call with the originating and terminating clients' location to suppress BCP insertion. Note that even though the originating and terminating clients are at the same location, a BCP is still inserted to the call if no Routability Group is configured with the location. When this parameter is set to true, the setting of "InsertPortalWhenAnyBFW" is ignored.

157.3 Description

This activity provides operational measurement enhancements for Border Control Point (BCP) usage. These enhancements are intended to provide some degree of parity between the GWC and the SIP Session Manager view of BCP performance measurements. Refer to Table 1: Session Manager vs GWC OMs for details on where the two diverge. This activity requests that additional Performance Measurements related to the BCP usage be generated on:

- Each controlling Session Manager
- Each Border Control Point

Table 1: Session Manager vs GWC OMs

OM	Session Manager	GWC
sesmSuccessCalls (GWC equivalent: “GWC successful calls” 5/10)	1 call = many BCPs Media streams for a single call may be distributed over multiple BCPs (e.g. audio + video + data).	1 call = 1 BCP Media streams for a single call are co-located on a single BCP.
sesmFailedCalls (GWC equivalent: “GWC failed calls” 5/10)	1 call = many BCPs Media stream for a single call may be distributed over multiple BCPs (e.g. audio + video + data) For example: a multimedia call (audio + video + data) would fail if any of the 3 policy rules on any of the BCPs suffered a failure.	1 call = 1 BCP Media streams for a single call are co-located on a single BCP.
mediaPortalCount (GWC equivalent: “Number of provisioned Media Proxies”)	The number of BCPs configured in the Management Console to support this Session Manager	The number of BCPs provisioned to support this GWC.
sesmSuccessStreams (GWC equivalent: “Media Proxy successful calls” 5/10)	(per-Stream) The number of stream setup requests (policy rules) that were successfully processed by this BCP.	(per-Call) The number of calls successfully setup by this BCP.
sesmFailedStreams (GWC equivalent: “Media Proxy failed calls” 5/10)	(per-Stream) The number of stream setup requests (policy rules) that were not successfully processed by this BCP.	(per-Call) The number of calls that failed to be setup by this BCP.

157.3.1 Session Manager OMs

157.3.1.1 Media Portal

There are three new OM Registers added to the OM Group “MediaPortal” defined in Table 2: OM Group Media Portal - New OM Registers. Figure 6: Example GUI snapshot of MediaPortal OM Group shows the new OM Registers in the OM Browser GUI.
